For the *stage 1 Hyp mode* instructions, the last letter of the instruction name is **R** for the read operation and **W** for the write operation.

See also [Encoding and availability of the address translation instructions on page G4-4684](#).

ATS1C**, Address translation stage 1, current Security state

Any VMSAv8-32 implementation supports the ATS1C** instructions. They can be executed by any software executing at PL1 or higher, in either Security state.

The ATS1C** instructions are [ATS1CPR](#), [ATS1CPW](#), [ATS1CUR](#), and [ATS1CUW](#) and, when [ARMv8.2-ATS1E1 is implemented](#), [ATS1CPRP](#) and [ATS1CPWP](#). These instructions perform the address translations of the PL1&0 translation regime.

In an implementation that includes EL2, when executed in Non-secure state, these instructions return the IPA that is the output address of the stage 1 translation. [Figure G4-1 on page G4-4560](#) shows the different translation regimes.

———— Note ————

The Non-secure PL1 and PL0 modes have no visibility of the stage 2 address translations, that can be defined only at PL2, and translate IPAs to be PAs.

See [Determining the PAR format on page G4-4686](#) for the format used when returning the result of these instructions.

ATS12NSO**, Address translation stages 1 and 2, Non-secure state only

A VMSAv8-32 implementation supports the ATS12NSO** instructions only if it includes EL2. In an implementation that includes EL2, in AArch32 state, they can be executed:

- By software executing in Non-secure state at EL2. This means by software executing in Hyp mode.
- If the implementation includes EL3, when EL3 is using AArch32, by software executing in Secure state at PL1.

The ATS12NSO** instructions are [ATS12NSOPR](#), [ATS12NSOPW](#), [ATS12NSOUR](#), and [ATS12NSOUW](#).

In an implementation that includes EL3, when EL3 is using AArch64 and EL1 is using AArch32, any execution of an ATS12NSO** instruction at Secure EL1 is trapped as an exception that is taken to EL3.

In an implementation that does not include EL2, but includes EL3, when EL3 is using AArch32 these instructions are not UNDEFINED but each instruction behaves in the same way as the equivalent [ATS1C**](#) instruction.

If an implementation does not include EL2 and does not include EL3 then these instructions are CONSTRAINED UNPREDICTABLE, with the permitted behavior that the instructions are UNDEFINED, see [Unallocated System register access instructions on page K1-6100](#).

ARM deprecates use of these instructions from any Secure PL1 mode other than Monitor mode.

In Secure state and in Non-secure Hyp mode these instructions perform the translations made by the Non-secure PL1&0 translation regime.

These instructions always return the PA and final attributes generated by the translation. That is, for an implementation that includes EL2, they return:

- The result of the two stages of address translation for the specified Non-secure input address.
- The memory attributes obtained by the combination of the stage 1 and stage 2 attributes.

———— **Note** —————

From Hyp mode, the **ATS1C**** and **ATS12NSO**** instructions both return the results of address translations that would be performed in the Non-secure modes other than Hyp mode. The difference is:

- The **ATS1C**** instructions return the Non-secure PL1 view of the associated address translation. That is, they return the IPA output address corresponding to the VA input address.
- The **ATS12NSO**** instructions return the EL2, or Hyp mode, view of the associated address translation. That is, they return the PA output address corresponding to the VA input address, generated by two stages of translation.

See [Determining the PAR format on page G4-4686](#) for the format used when returning the result of these instructions.

ATS1H*, Address translation stage 1, Hyp mode

A VMSAv8-32 implementation supports the **ATS1H*** instructions only if it includes EL2. They can be executed by:

- Software executing in Non-secure state at PL2. This means by software executing in Hyp mode.
- Software executing in Secure state in Monitor mode.

The **ATS1H*** instructions are **ATS1HR** and **ATS1HW**. In an implementation that includes EL3, these instructions are **CONSTRAINED UNPREDICTABLE** if executed in a Secure PL1 mode other than Monitor mode, see [Hyp mode VA to PA address translation instructions on page K1-6116](#).

If an implementation does not include EL2 then these instructions are **CONSTRAINED UNPREDICTABLE**, with the permitted behavior that the instructions are **UNDEFINED**, see [Unallocated System register access instructions on page K1-6100](#).

These instructions perform the translations made by the Non-secure EL2 translation regime. The instruction takes a VA input address and returns a PA output address.

These instructions always return a result in a 64-bit format **PAR**.

G4.13.2 Encoding and availability of the address translation instructions

Software executing at PL0 never has any visibility of the address translation instructions, but software executing at PL1 or higher can use the unprivileged address translation instructions to find the address translations used for memory accesses by software executing at PL0 and PL1.

———— **Note** —————

For information about translations when the stage of address translation is disabled see [The effects of disabling address translation stages on VMSAv8-32 behavior on page G4-4567](#).

[Table G4-34](#) shows the encodings for the address translation instructions, and their availability in different implementations in different PE modes and states.

Table G4-34 Address translation instructions in AArch32 state

opc1	CRm	opc2	Name	Type	Description
All VMSAv8-32 implementations, in all modes, at PL1 or higher, see ATS1C**, Address translation stage 1, current Security state on page G4-4683					

Table G4-34 Address translation instructions in AArch32 state (continued)

opc1	CRm	opc2	Name	Type	Description
0	c8	0	ATS1CPR	WO	PL1 stage 1 read translation, current state
		1	ATS1CPW	WO	PL1 stage 1 write translation, current state
		2	ATS1CUR	WO	Unprivileged stage 1 read translation, current state
		3	ATS1CUW	WO	Unprivileged stage 1 write translation, current state
c9	0	0	ATS1CPR^a	WO	PL1 stage 1 read translation, current state, PSTATE.PAN ^a
		1	ATS1CPW^a	WO	PL1 stage 1 write translation, current state, PSTATE.PAN ^a
Implementation includes EL2, in Non-secure Hyp mode and Secure PL1 modes, see ATS12NSO** , Address translation stages 1 and 2, Non-secure state only on page G4-4683					
0	c8	4	ATS12NSOPR	WO	Non-secure PL1 stage 1 and 2 read translation
		5	ATS12NSOPW	WO	Non-secure PL1 stage 1 and 2 write translation
		6	ATS12NSOUR	WO	Non-secure unprivileged stage 1 and 2 read translation
		7	ATS12NSOUW	WO	Non-secure unprivileged stage 1 and 2 write translation
Implementation includes EL2, in Non-secure Hyp mode and Secure Monitor mode, see ATS1H* , Address translation stage 1, Hyp mode on page G4-4684					
4	c8	0	ATS1HR	WO	Hyp mode stage 1 read translation
		1	ATS1HW	WO	Hyp mode stage 1 write translation

a. **Instruction only supported when ARMv8.2-ATS1E1 is implemented.**

The result of an instruction is always returned in the [PAR](#). The [PAR](#) is a RW register and:

- In all implementations, the 32-bit format [PAR](#) is accessed using an MCR or MRC instruction with CRn set to c7, CRm set to c4, and opc1 and opc2 both set to 0.
- The 64-bit format [PAR](#) is accessed using an MCRR or MRRC instruction with CRm set to c7, and opc1 set to 0.

Address translation instructions that are not available in a particular implementation are reserved and CONSTRAINED UNPREDICTABLE. For example:

- In an implementation that does not include EL2, the encodings with an opc1 value of 4 are reserved and CONSTRAINED UNPREDICTABLE. These are the [ATS1H*](#) instructions.
- In an implementation that does not include either EL2 or EL3, the encodings with opc2 values of 4-7 are reserved and CONSTRAINED UNPREDICTABLE. These are the [ATS12NSO**](#) instructions.

The CONSTRAINED UNPREDICTABLE behavior of these encodings is that they are UNDEFINED, see [Unallocated System register access instructions on page K1-6100](#).

G4.13.3 Determining the PAR format

The PAR is a 64-bit register, that supports both 32-bit and 64-bit PAR formats. This section describes how the PAR format is determined, for returning a result from each of the groups of address translation instructions. The returned result might be the translated address, or might indicate a fault on the translation, see *Handling of faults and aborts during an address translation instruction*.

ATSIC** instructions

Address translations for the current state. From modes other than Hyp mode:

- TTBCR.EAE determines whether the result is returned using the 32-bit or the 64-bit PAR format.
- If the implementation includes EL3, the translation performed is for the current Security state and, depending on that state:
 - The Secure or Non-secure TTBCR.EAE determines the PAR format.
 - The result is returned to the Secure or Non-secure instance of the PAR

Instructions executed in Hyp mode always return a result to the Non-secure PAR, using the 64-bit format.

ATS12NSO** instructions

Address translations for the Non-secure PL1 and PL0 modes. These instructions return a result using the 64-bit PAR format if at least one of the following is true:

- The Non-secure TTBCR.EAE bit is set to 1.
- The implementation includes EL2, and the value of HCR.VM is 1.

Otherwise, the instruction returns a result using the 32-bit PAR format.

Instructions executed in a Secure PL1 mode return a result to the Secure PAR. Instructions executed in Hyp mode return a result to the Non-secure PAR.

ATS1H* instructions

Address translations from Hyp mode. These instructions always return a result using the 64-bit PAR format.

Instructions executed in Secure Monitor mode return a result to the Secure PAR. Instructions executed in Non-secure Hyp mode return a result to the Non-secure PAR.

G4.13.4 Handling of faults and aborts during an address translation instruction

When a stage of address translation is enabled, any corresponding address translation instruction requires a translation table lookup, and this might require a translation table walk. However, the input address for the translation might be a faulting address, either because:

- The translation table entries used for the translation indicate a fault.
- A stage 2 fault or an external abort occurs on the required translation table walk.

VMSAv8-32 memory aborts on page G4-4649 describes the faults that might occur on a translation table walk in AArch32 state.

How the fault is handled, and whether it generates an exception, depends on the cause of the fault, as described in:

- *MMU fault on an address translation instruction*.
- *External abort during an address translation instruction on page G4-4687*.
- *Stage 2 fault on a current state address translation instruction on page G4-4688*.

MMU fault on an address translation instruction

In the following cases, an MMU fault on an address translation is reported in the PAR, and no abort is taken. This rule applies:

- To a faulting address translation instruction executed in Hyp mode, or in a Secure PL1 mode.

- To a faulting address translation instruction executed in a Non-secure PL1 mode, for cases where the fault would generate a stage 1 abort if it occurred on the equivalent load or store operation.

Using the PAR to report a fault on an address translation instruction gives more information about how these faults are reported.

Note

- The Domain fault encodings shown in [Table G4-26 on page G4-4670](#) are used only for reporting a fault on an address translation instruction that uses the 64-bit PAR format. That is, they are used only in an implementation that includes EL2, and are used for reporting a Domain fault on either:
 - An *ATS1C*** instruction executed in Hyp mode.
 - An *ATS12NSO*** instruction executed when the value of HCR.VM is 1.These encodings are never used for fault reporting in the *DFSR*, *IFSR*, or *HSR*.
- For an address translation instruction executed in a Non-secure PL1 mode, for a fault that would generate a stage 2 abort if it occurred on the equivalent load or store operation, the stage 2 abort is generated as described in *Stage 2 fault on a current state address translation instruction on page G4-4688*.

Using the PAR to report a fault on an address translation instruction

For a fault on an address translation instruction for which no abort is taken, the PAR is updated with the following information, to indicate the fault:

- The fault code, that would normally be written to the Fault status register. The code used depends on the current translation table format, as described in either:
 - *PL1 fault reporting with the Short-descriptor translation table format on page G4-4668*.
 - *PL1 fault reporting with the Long-descriptor translation table format on page G4-4670*.See also the Note at the start of *Determining the PAR format on page G4-4686* about the Domain fault encodings shown in [Table G4-26 on page G4-4670](#).
- A status bit, that indicates that the translation operation failed.

The fault does not update any Fault Address Register.

External abort during an address translation instruction

As stated in *External abort on a translation table walk on page G4-4659*, an external abort on a translation table walk generates a Data Abort exception. The abort can be synchronous or asynchronous, and behaves as follows:

Synchronous external abort on a translation table walk

The fault status and fault address registers of the Security state to which the abort is taken are updated. The fault status register indicates the appropriate external abort on a Translation fault, and the fault address register indicates the input address for the translation.

The PAR is UNKNOWN.

Asynchronous external abort on a translation table walk

The fault status register of the Security state to which the abort is taken is updated, to indicate the asynchronous external abort. No fault address registers are updated.

The PAR is UNKNOWN.

Stage 2 fault on a current state address translation instruction

If the PE is in a Non-secure PL1 mode and executes one of the [ATS1C**](#) instructions, then a fault in the stage 2 translation of an address accessed in a stage 1 translation table lookup generates an exception. This is equivalent to the case described in [Stage 2 fault on a stage 1 translation table walk](#) on page G4-4656. When this fault occurs on an [ATS1C**](#) address translation instruction:

- A Hyp Trap exception is taken to Hyp mode.
- The [PAR](#) is UNKNOWN.
- The [HSR](#) indicates that:
 - The fault occurred on a translation table walk.
 - The operation that faulted was a cache maintenance instruction.
- The [HPFAR](#) holds the IPA that faulted.
- The [HDFAR](#) holds the VA that the executing software supplied to the address translation instruction.

G4.14 About the System registers for VMSAv8-32

The System registers and System instructions that are accessible in AArch32 state are almost all in the encoding space described in *The AArch32 System register interface* on page G1-4408. This section gives general information about these registers, which comprise:

- Registers in the (coproc==0b1111) encoding space, that provide control and status information for the PE in Non-debug state.
- Registers in the (coproc==0b1110) encoding space, including:
 - Debug registers.
 - Trace registers.
 - Legacy execution environment registers.

VMSAv8-32 organization of registers in the (coproc==0b1110) encoding space on page G4-4704 summarizes the registers in the (coproc==0b1110) encoding space, and indicates where these registers are described, either in this manual or in other architecture specifications.

VMSAv8-32 organization of registers in the (coproc==0b1111) encoding space on page G4-4707 summarizes the registers in the (coproc==0b1111) encoding space, and indicates where in this manual these registers are described.

This section gives general information about the AArch32 System registers, and the conventions used in describing these registers.

———— Note —————

Many implementations include other interfaces to some System registers, for example a memory-mapped interface to some debug System registers. These are described in the appropriate sections of this manual.

This section is organized as follows:

- *About AArch32 System register accesses.*
- *Classification of System registers* on page G4-4692.
- *Synchronization of changes to AArch32 System registers* on page G6-4768.
- *Fixed values in register diagrams* on page G4-4701.
- *Principles of the ID scheme for fields in ID registers* on page G4-4701.

G4.14.1 About AArch32 System register accesses

The following subsections give more information about accesses to the AArch32 System registers:

- *Ordering of reads of System registers.*
- *Accessing 32-bit System registers* on page G4-4690.
- *Accessing 64-bit System registers* on page G4-4691.

Ordering of reads of System registers

Reads of the System registers can occur out of order with respect to earlier instructions executed on the same PE, provided that both:

- Any data dependencies between the instructions, as specified in *Synchronization of changes to AArch32 System registers* on page G6-4768, including read-after-read dependencies, are respected.
- The reads to the register do not occur earlier than the most recent *Context synchronization event* to its architectural position in the instruction stream.

———— Note —————

In particular, the values read from System registers that hold self-incrementing counts, such as the Performance Monitors counters or the Generic Timer counter or timers, could be accessed from any time after the previous *Context synchronization event*. For example, where a memory access is used to communicate a read of such

counters, an ISB must be inserted between the read of the memory location that is known to have returned its data, either as a result of a condition on that data or of the write being completed, and the read of the Generic Timer counter, if it is necessary that the Generic Timer counter returns a count value after the memory communication.

Accessing 32-bit System registers

Software accesses most 32-bit System registers using the generic MCR and MRC System register access instructions, specifying some or all of the parameters {coproc, CRn, opc1, CRm, opc2}, where:

coproc	Identifies the primary region of the System register encoding space. Takes one of the values: p14 Encoded as 0b1110. p15 Encoded as 0b1111.
CRn	Takes a value in the range c0-c15, encoded the corresponding 4-bit binary value, 0b0000-0b1111. In the (coproc==0b1110) encoding space, the opc1 value identifies the System register functional group, and CRn is the most significant identifier for the required register within that group. In the (coproc==0b1111) encoding space, CRn is the most significant identifier for the required register.
opc1	Takes a value in the range 0-7, encoded as its 3-bit binary value. In the (coproc==0b1110) encoding space, the opc1 value identifies the System register functional group, and can take the following values: 0 Debug System registers. 1 Trace System registers. 7 Legacy Jazelle System registers. In the (coproc==0b1111) encoding space, opc1 can take any value in the range 0-7.
CRm	Takes a value in the range c0-c15, encoded the corresponding 4-bit binary value, 0b0000-0b1111.
opc2	Takes a value in the range 0-7, encoded as its 3-bit binary value. opc2 is optional in the MCR and MRC instruction syntax, and if no value is specified the encoding defaults to 0b000.
Rt	A general-purpose register to hold a 32-bit value to transfer to or from the System register. Takes a value in the range R0-R14, encoded as the corresponding 4-bit binary value, 0b0000-0b1110.

This means an MCR or MRC access to a specific 32-bit System register uses:

- A unique combination of coproc, CRn, opc1, CRm, and opc2, to specify the required System register.
- A general-purpose register, Rt, for the transferred 32-bit value.

See also:

- [MCR on page F5-3249](#).
- [MRC on page F5-3271](#).

A small number of AArch32 debug System registers are accessed using LDC or STC instructions. In these cases, the register to be accessed is identified in the instruction syntax by the use of p14, c5 where:

p14	Identifies that the access is to the (coproc==0b1110) encoding space.
c5	Identifies the target debug System register.

See the instruction descriptions:

- [LDC \(immediate\) on page F5-3140](#).
- [LDC \(literal\) on page F5-3142](#).
- [STC on page F5-3478](#).

The only uses of LDC and STC permitted in ARMv8-A are:

- An LDC access to load data from memory to `DBGDTRTXint`, see [LDC \(immediate\) on page F5-3140](#) and [LDC \(literal\) on page F5-3142](#).
- An STC access to store data to memory from `DBGDTRRXint`, see [STC on page F5-3478](#).

A small number of AArch32 System registers are accessed using MRS, MSR, VMRS, or VMSR instructions, see the appropriate register and instruction description for more information, see:

- [MRS on page F5-3275](#).
- [MSR \(immediate\) on page F5-3285](#),
- [MSR \(register\) on page F5-3287](#).
- [VMRS on page F6-4017](#).
- [VMSR on page F6-4020](#).

Note

- For example:
 - The [APSR](#), [CPSR](#), and [SPSR](#) are accessed using MRS or MSR instructions.
 - The [MVFR0](#), [MVFR1](#), and [MVFR2](#) are accessed using VMRS or VMSR instructions.
 - In addition, the banked register forms of the MRS and MSR instructions can be used to access some System registers that are associated with PE modes other than the mode in which the PE is currently executing, see [MRS \(Banked register\) on page F5-3277](#) and [MSR \(Banked register\) on page F5-3281](#).
-

Accessing 64-bit System registers

Software accesses a 64-bit System register using the generic MCRR and MRRC System register access instructions, specifying the parameters {coproc, CRm, opc1}, where:

coproc	Identifies the primary region of the System register encoding space. Takes one of the values: p14 Encoded as 0b1110. p15 Encoded as 0b1111.
CRm	Takes a value in the range c0-c15, encoded the corresponding 4-bit binary value, 0b0000-0b1111. In the (coproc==0b1110) encoding space, the opc1 value identifies the System register functional group, and CRm is the most significant identifier for the required register within that group. In the (coproc==0b1111) encoding space, CRm is the most significant identifier for the required register.
opc1	Takes a value in the range 0-15, encoded as its 3-bit binary value. In the (coproc==0b1110) encoding space, the opc1 value identifies the System register functional group, and can take the following values: 0 Debug System registers. 1 Trace System registers. In the (coproc==0b1111) encoding space, opc1 can take any value in the range 0-15.
Rt	A general-purpose register to hold bits[31:0] of the value to transfer to or from the System register. Takes a value in the range R0-R14, encoded as the corresponding 4-bit binary value, 0b0000-0b1110.
Rt2	A general-purpose register to hold bits[63:32] of the value to transfer to or from the System register. Takes a value in the range R0-R14, encoded as the corresponding 4-bit binary value, 0b0000-0b1110.

This means an MCRR or MRRC access to a specific 64-bit System register uses:

- A unique combination of coproc, CRm and opc1, to specify the required 64-bit System register.
- Two general-purpose registers, each holding 32 bits of the value to transfer.

This means a PE can access a 64-bit System register using:

- An MCRR instruction to write to a System register, see [MCRR on page F5-3251](#).
- An MRRC instruction to read a System register, see [MRRC on page F5-3251](#).

When using an MCRR or MRRC instruction the System register access is 64-bit atomic.

Some 64-bit registers also have an MCR and MRC encoding. The MCR and MRC encodings for these registers access the least significant 32 bits of the register. For example, to access the [PAR](#), software can:

- Use the following instructions to access all 64 bits of the register:
MRRC p15, 0, <Rt>, <Rt2>, c7 ; Read 64-bit PAR into Rt (low word) and Rt2 (high word)
MCRR p15, 0, <Rt>, <Rt2>, c7 ; Write Rt (low word) and Rt2 (high word) to 64-bit PAR

- Use the following instructions to access the least significant 32 bits of the register:
 MRC p15, 0, <Rt>, c7, c4, 0 ; Read PAR[31:0] into Rt
 MCR p15, 0, <Rt>, c7, c4, 0 ; Write Rt to PAR[31:0]

G4.14.2 Classification of System registers

Features provided by EL3 and EL2 integrate with many features of the architecture. Therefore, the descriptions of the individual System registers include information about how these Exception levels affect the register. This section:

- Summarizes how EL3 and EL2 affect the implementation of the System registers, and the classification of those registers.
- Summarizes how EL3 controls access to the System registers.
- Describes an EL3 signal that can control access to some registers in the (coproc==0b1111) encoding space.

It contains the following subsections:

- [Banked System registers](#).
- [Restricted access System registers on page G4-4694](#).
- [Configurable access System registers on page G4-4694](#).
- [EL2-mode System registers on page G4-4695](#).
- [Common System registers on page G4-4698](#).
- [The CP15SDISABLE input signal on page G4-4699](#).
- [Access to registers from Monitor mode on page G4-4700](#).

———— Note ————

EL3 defines the register classifications of Banked, Restricted access, Configurable, and Common. EL2 defines the EL2-mode classification.

It is IMPLEMENTATION DEFINED whether each IMPLEMENTATION DEFINED register is Banked, Restricted access, Configurable, EL2-mode, or Common.

Banked System registers

In an implementation that includes EL3 using AArch32, some System registers are Banked. Banked System registers have two copies, one Secure and one Non-secure. The SCR.NS bit selects the Secure or Non-secure instance of the register. [Table G4-35](#) shows which registers in the (coproc==0b1111) encoding space are Banked in this way, and the permitted access to each register. No registers in the (coproc==0b1110) encoding space are Banked.

Table G4-35 Banked (coproc==0b1110) System registers

Banked register	Permitted accesses ^a
ACTLR , Auxiliary Control Register	Read/write only at PL1 or higher
ACTLR2 , Auxiliary Control Register 2	Read/write only at PL1 or higher.
ADFSR , Auxiliary Data Fault Status Register	Read/write only at PL1 or higher
AIFSR , Auxiliary Instruction Fault Status Register	Read/write only at PL1 or higher
AMAIR0 , Auxiliary Memory Attribute Indirection Register 0	Read/write only at PL1 or higher
AMAIR1 , Auxiliary Memory Attribute Indirection Register 1	Read/write only at PL1 or higher
CNTP_CTL , Counter-timer Physical Timer Control register	Read/write only at PL0 or higher ^b
CNTP_CVAL , Counter-timer Physical Timer CompareValue register	Read/write at PL0 or higher ^b
CNTP_TVAL , Counter-timer Physical Timer TimerValue register	Read/write at PL0 or higher ^b

Table G4-35 Banked (coproc==0b1110) System registers (continued)

Banked register	Permitted accesses^a
CONTEXTIDR , Context ID Register	Read/write only at PL1 or higher
CSSELR , Cache Size Selection Register	Read/write only at PL1 or higher
DACR , Domain Access Control Register	Read/write only at PL1 or higher
DFAR , Data Fault Address Register	Read/write only at PL1 or higher
DFSR , Data Fault Status Register	Read/write only at PL1 or higher
IFAR , Instruction Fault Address Register	Read/write only at PL1 or higher
IFSR , Instruction Fault Status Register	Read/write only at PL1 or higher
MAIR0 , Memory Attribute Indirection Register 0	Read/write only at PL1 or higher
MAIR1 , Memory Attribute Indirection Register 1	Read/write only at PL1 or higher
NMRR , Normal Memory Remap Register	Read/write only at PL1 or higher
PAR , Physical Address Register	Read/write only at PL1 or higher
PRRR , Primary Region Remap Register	Read/write only at PL1 or higher
SCTLR , System Control Register ^c	Read/write only at PL1 or higher
TPIDRPRW , EL1 only Thread ID	Read/write only at PL1 or higher
TPIDRURO , User Read-only Thread ID	Read-only at PL0 Read/write at PL1 or higher
TPIDRURW , User Read/Write Thread ID	Read/write at PL0 or higher
TTBCR , Translation Table Base Control	Read/write only at PL1 or higher
TTBCR2 , Translation Table Base Control 2	Read/write only at PL1 or higher
TTBR0 , Translation Table Base 0	Read/write only at PL1 or higher
TTBR1 , Translation Table Base 1	Read/write only at PL1 or higher
VBAR , Vector Base Address Register	Read/write only at PL1 or higher

- a. Any attempt to execute an access that is not permitted results in an Undefined Instruction exception.
- b. PL0 access is configurable, see the register description for more information.
- c. Some bits are common to the Secure and the Non-secure copies of the register, see [SCTLR, System Control Register](#) on page G6-5106.

A Banked System register can contain a mixture of:

- Fields that are Banked.
- Fields that are read-only in Non-secure PL1 or PL2 modes but read/write in the Secure state.

The System Control Register [SCTLR](#) is an example of a register of that contains this mixture of fields.

The Secure copies of the Banked System registers are sometimes referred to as the Secure Banked System registers. The Non-secure copies of the Banked System registers are sometimes referred to as the Non-secure Banked System registers.

Restricted access System registers

In an implementation that includes EL3, some System registers are present only in Secure state. These are called *Restricted access* registers, and their read/write access permissions are:

- In Non-secure state, software cannot modify Restricted access registers.
- For the **NSACR**, in Non-secure state:
 - Software running at PL1 or higher can read the register.
 - Unprivileged software, meaning software running at PL0, cannot read the register.

This means that Non-secure software running at PL1 or higher can read the access permissions for System registers that have Configurable access.

If EL3 is using AArch64 then any read of the **NSACR** from Non-secure EL2 using AArch32, or Non-secure EL1 using AArch32, returns the value `0x00000C00`.
- For all other Restricted access registers, Non-secure software cannot read the register.

In an implementation that does not include EL3:

- **SDER** is implemented only in Secure state.
- Any read of the **NSACR** returns the value `0x00000C00`.
- All other accesses to Restricted access System registers are UNDEFINED.

Table G4-36 shows the Restricted access System registers in the (coproc==0b1111) encoding space. There are no Restricted access registers in the (coproc==0b1110) encoding space.

Table G4-36 Restricted access (coproc==0b1111) System registers

Register	Permitted accesses ^a
SCR , Secure Configuration	Read/write in Secure PL1 modes
SDCR , Secure Debug Configuration Register	Read/write in Secure PL1 modes
SDER , Secure Debug Enable	Read/write in Secure PL1 modes
NSACR , Non-Secure Access Control	Read/write in Secure PL1 modes Read-only in Non-secure PL1 and PL2 modes
MVBAR , Monitor Vector Base Address	Read/write in Secure PL1 modes

a. Any attempt to execute an access that is not permitted results in an Undefined Instruction exception.

Configurable access System registers

Secure software can configure the access to some System registers. These registers are called Configurable access registers, and the control can be:

- A bit in the control register determines whether the register is:
 - Accessible from Secure state only.
 - Accessible from both Secure and Non-secure states.
- A bit in the control register changes the accessibility of a register bit or field. For example, setting a bit in the control register might mean that a RW field behaves as RAZ/WI when accessed from Non-secure state.

Bits in the **NSACR** control access.

In an AArch32 implementation that includes EL3:

- There are no Configurable access System registers in the (coproc==0b1110) encoding space.
- The only required Configurable access register in the (coproc==0b1111) encoding space is the **CPACR**.
- The following Advanced SIMD and floating point System registers are Configurable access:
 - Floating-point Status and Control Register, **FPSCR**

- Floating-point Exception register, [FPEXC](#).
- Floating-point System ID register, [FPSID](#).
- Media and VFP Feature Register 0, [MVFR0](#).
- Media and VFP Feature Register 1, [MVFR1](#).
- Media and VFP Feature Register 2, [MVFR2](#).

EL2-mode System registers

In an implementation that includes EL2, if EL2 can use AArch32, the implementation provides a number of registers for use in the EL2 mode, Hyp mode. As with other System register encodings, some of these register encodings provide write-only operations. When the implementation includes EL3 and EL3 is using AArch32, these registers are also accessible from Monitor mode when the value of [SCR.NS](#) is 1.

The following subsections describe the EL2-mode registers:

- [Hyp mode read/write registers in the \(coproc==0b1111\) encoding space](#).
- [Hyp mode encodings for shared \(coproc==0b1111\) System registers on page G4-4696](#).
- [Hyp mode \(coproc==0b1111\) write-only System instructions on page G4-4697](#).

There are no EL2-mode registers in the (coproc==0b1110) encoding space.

Hyp mode read/write registers in the (coproc==0b1111) encoding space

These registers are implemented only in Non-secure state, and in Non-secure state they are accessible only from Hyp mode.

Except for accesses to [CNTVOFF](#) in an implementation that includes EL3 but not EL2, the behavior of accesses to these registers is as follows:

- In Secure state, the registers can be accessed from EL3 when [SCR.NS](#) is set to 1, see [Access to registers from Monitor mode on page G4-4700](#).
- The following accesses are UNDEFINED:
 - Accesses from Non-secure PL1 modes.
 - Accesses in Secure state when [SCR.NS](#) is set to 0.

In an implementation that includes EL3 but not EL2, the behavior of accesses to [CNTVOFF](#) is as follows:

- Any access from Secure Monitor mode is CONSTRAINED UNPREDICTABLE, regardless of the value of [SCR.NS](#). The CONSTRAINED UNPREDICTABLE behavior is that the access is UNDEFINED, see [Unallocated System register access instructions on page K1-6100](#).
- All other accesses are UNDEFINED.

———— **Note** ————

Except for [CNTVOFF](#), the Hyp mode registers are part of EL2, meaning they are implemented only if the implementation includes EL2. However, conceptually, [CNTVOFF](#) is part of any implementation of the Generic Timer, see [Status of the CNTVOFF register on page G5-4757](#). This means the behavior of [CNTVOFF](#) in an implementation that does not include EL2 is not covered by the general definition of the behavior of the Hyp mode (coproc==0b1111) read/write registers.

Table G4-37 shows the Hyp mode read/write System registers, in the (coproc==0b1111) encoding space:

Table G4-37 Hyp mode (coproc==0b1111) read/write System registers

Register	Width	Permitted accesses ^a
VPIDR	32-bit	Read/write. In Non-secure state, accessible only from Hyp mode
VMPIDR	32-bit	Read/write. In Non-secure state, accessible only from Hyp mode
HSCTLR	32-bit	Read/write. In Non-secure state, accessible only from Hyp mode
HACTLR	32-bit	Read/write. In Non-secure state, accessible only from Hyp mode
HACTLR2	32-bit	Read/write. In Non-secure state, accessible only from Hyp mode.
HCR	32-bit	Read/write. In Non-secure state, accessible only from Hyp mode
HDCCR	32-bit	Read/write. In Non-secure state, accessible only from Hyp mode
HCPTR	32-bit	Read/write. In Non-secure state, accessible only from Hyp mode
HSTR	32-bit	Read/write. In Non-secure state, accessible only from Hyp mode
HACR	32-bit	Read/write. In Non-secure state, accessible only from Hyp mode
HTCR	32-bit	Read/write. In Non-secure state, accessible only from Hyp mode
VTCR	32-bit	Read/write. In Non-secure state, accessible only from Hyp mode
HTTBR	64-bit	Read/write. In Non-secure state, accessible only from Hyp mode
VTTBR	64-bit	Read/write. In Non-secure state, accessible only from Hyp mode
HADFSR	32-bit	Read/write. In Non-secure state, accessible only from Hyp mode
HAIFSR	32-bit	Read/write. In Non-secure state, accessible only from Hyp mode
HSR	32-bit	Read/write. In Non-secure state, accessible only from Hyp mode
HPFAR	32-bit	Read/write. In Non-secure state, accessible only from Hyp mode
HMAIR0	32-bit	Read/write. In Non-secure state, accessible only from Hyp mode
HMAIR1	32-bit	Read/write. In Non-secure state, accessible only from Hyp mode
HAMAIR0	32-bit	Read/write. In Non-secure state, accessible only from Hyp mode
HAMAIR1	32-bit	Read/write. In Non-secure state, accessible only from Hyp mode
HVBAR	32-bit	Read/write. In Non-secure state, accessible only from Hyp mode
HTPIDR	32-bit	Read/write. In Non-secure state, accessible only from Hyp mode
CNTVOFF ^b	64-bit	Read/write. In Non-secure state, accessible only from Hyp mode

a. Any attempt to execute an access that is not permitted results in an Undefined Instruction exception.

b. Implemented in any implementation of the Generic Timer. See, also, the Note earlier in this section.

Hyp mode encodings for shared (coproc==0b1111) System registers

Some Hyp mode registers share the Secure instance of an existing Banked register. In this case the implementation includes an encoding for the register that is accessible only in Hyp mode, or in Monitor mode when `SCR.NS` is set to 1.

For these registers, the following accesses are UNDEFINED:

- Accesses from Non-secure PL1 modes.
- Accesses in Secure state when `SCR.NS` is set to 0.

Table G4-38 lists the Hyp mode encodings for shared registers.

Table G4-38 Hyp mode (coproc==0b1111) System register encodings for shared registers

Register	Permitted accesses ^a	Shared register
HDFAR	Read/write. Accessible from Hyp mode, or from Monitor mode when <code>SCR.NS</code> is set to 1.	Secure DFAR
HIFAR	Read/write. Accessible from Hyp mode, or from Monitor mode when <code>SCR.NS</code> is set to 1.	Secure IFAR

a. Any attempt to execute an access that is not permitted results in an Undefined Instruction exception.

In Monitor mode, the Secure copies of these registers can be accessed either:

- Using the [DFAR](#) or [IFAR](#) encoding with `SCR.NS` set to 0.
- Using the [HDFAR](#) or [HIFAR](#) encoding with `SCR.NS` set to 1.

However, between accessing a register using one alias and accessing the register using the other alias, a *Context synchronization event* is required to ensure the ordering of the accesses.

Hyp mode (coproc==0b1111) write-only System instructions

Architecturally, these encodings are an extension of the Banked register encodings described in *Banked System registers on page G4-4692*, where:

- The implementation does not implement the operation in Secure state.
- In Non-secure state, the operation is accessible only at EL2, that is, only from Hyp mode.

In Secure state:

- These instructions can be accessed from Monitor mode regardless of the value of `SCR.NS`, see *Access to registers from Monitor mode on page G4-4700*.
- Accesses to these instructions are CONstrained UNPREDICTABLE if executed in a Secure mode other than Monitor mode, see *Hyp mode TLB maintenance instructions on page K1-6116* and *Hyp mode VA to PA address translation instructions on page K1-6116*.

Accesses to these instructions are UNDEFINED if accessed from a Non-secure PL1 mode.

Table G4-39 shows the EL2-mode write-only instructions in the (coproc==0b1111) encoding space:

Table G4-39 Hyp mode (coproc==0b1111) write-only System instructions

Register	Width	Permitted accesses ^a
ATS1HR	32-bit	Write-only. Accessible only from Hyp mode and Monitor mode
ATS1HW	32-bit	Write-only. Accessible only from Hyp mode and Monitor mode
TLBIALLHIS	32-bit	Write-only. Accessible only from Hyp mode and Monitor mode
TLBIMVAHIS	32-bit	Write-only. Accessible only from Hyp mode and Monitor mode
TLBIALLNSNHIS	32-bit	Write-only. Accessible only from Hyp mode and Monitor mode
TLBIALLH	32-bit	Write-only. Accessible only from Hyp mode and Monitor mode
TLBIMVAH	32-bit	Write-only. Accessible only from Hyp mode and Monitor mode
TLBIALLNSNH	32-bit	Write-only. Accessible only from Hyp mode and Monitor mode

- a. This section describes the behavior of write accesses that are not permitted. See also *Read-only and write-only register encodings* on page G6-4766.

Common System registers

Some System registers and operations are common to the Secure and Non-secure Security states. These are described as the *Common access* registers, or simply as the *Common* registers. These registers include:

- Read-only registers that hold configuration information.
- Register encodings used for various memory system operations, rather than to access registers.
- The *ISR*.
- All System registers in the (coproc==0b1110) encoding space.

Table G4-40 shows the Common System registers in the (coproc==0b1111) encoding space. These registers are not affected by whether EL3 is implemented.

Table G4-40 Common (coproc==0b1111) System registers

Register	Permitted accesses ^a
<i>MIDR</i> , Main ID Register	Read-only, only at EL1 or higher
<i>CTR</i> , Cache Type Register	Read-only, only at EL1 or higher
<i>TCMTR</i> , TCM Type Register ^b	Read-only, only at EL1 or higher
<i>TLBTR</i> , TLB Type Register ^b	Read-only, only at EL1 or higher
<i>MPIDR</i> , Multiprocessor Affinity Register	Read-only, only at EL1 or higher
<i>REVIDR</i> , Revision ID	Read-only, only at EL1 or higher
<i>ID_PFR0</i> , <i>ID_PFR1</i> , Processor Feature Registers	Read-only, only at EL1 or higher
<i>ID_DFR0</i> , Debug Feature Register 0	Read-only, only at EL1 or higher
<i>ID_AFR0</i> , Auxiliary Feature Register 0	Read-only, only at EL1 or higher
<i>ID_MMFR0</i> - <i>ID_MMFR4</i> , Memory Model Feature Registers	Read-only, only at EL1 or higher
<i>ID_ISAR0</i> - <i>ID_ISAR5</i> , Instruction Set Attribute Registers	Read-only, only at EL1 or higher
<i>CCSIDR</i> , Cache Size ID Register	Read-only, only at EL1 or higher
<i>CLIDR</i> , Cache Level ID Register	Read-only, only at EL1 or higher
<i>AIDR</i> , Auxiliary ID Register ^b	Read-only, only at EL1 or higher
<i>FCSEIDR</i> , FCSE PID Register	Read/write, only at EL1 or higher
Cache and branch predictor maintenance instruction	See <i>Cache maintenance instructions, functional group</i> on page G4-4734
Address translation instructions	See <i>Address translation instructions, functional group</i> on page G4-4737
<i>CP15DMB</i> , <i>CP15DSB</i> , <i>CP15ISB</i> memory barrier operations ^c	Write-only at all privilege levels, including EL0
TLB maintenance instructions	Write-only, only at EL1 or higher, see <i>TLB maintenance instructions, functional group</i> on page G4-4735
Performance monitors	See <i>Access permissions</i> on page D5-2176
<i>ISR</i> , Interrupt Status Register	Read-only, only at EL1 or higher

- a. Any attempt to execute an access that is not permitted results in an Undefined Instruction exception.
- b. Register or operation details are IMPLEMENTATION DEFINED.
- c. For performance reasons, ARM deprecates any use of these memory barrier operations.

Secure System registers for the (coproc==0b1111) encoding space

The Secure System registers in the (coproc==0b1111) encoding space comprise:

- The Secure copies of the Banked System registers in the (coproc==0b1111) encoding space.
- The Restricted access System registers in the (coproc==0b1111) encoding space.
- The Configurable access System registers in the (coproc==0b1111) encoding space that are configured to be accessible only from Secure state.

In an implementation that includes EL3, the Non-secure System registers are the System registers other than the Secure System registers.

The CP15SDISABLE input signal

When EL3 is using AArch32, it provides an input signal, **CP15SDISABLE**, that disables write access to some of the Secure registers when asserted HIGH. The **CP15SDISABLE** signal has no effect on:

- Register accesses from AArch64 state.
- Register accesses from Secure EL1 when EL3 is using AArch64 and EL1 is using AArch32.

————— **Note** —————

When EL3 is using AArch32, the interaction between **CP15SDISABLE** and any IMPLEMENTATION DEFINED register is IMPLEMENTATION DEFINED.

Table G4-41 shows the registers and operations affected.

Table G4-41 Secure registers affected by CP15SDISABLE

Register name	Affected operation
SCTLR, System Control Register	MCR p15, 0, <Rt>, c1, c0, 0
TTBR0, Translation Table Base Register 0	MCR p15, 0, <Rt>, c2, c0, 0
TTBCR, Translation Table Base Control Register	MCR p15, 0, <Rt>, c2, c0, 2
TTBCR2, Translation Table Base Control Register 2	MCR p15, 0, <Rt>, c2, c0, 3
DACR, Domain Access Control Register	MCR p15, 0, <Rt>, c3, c0, 0
PRRR, Primary Region Remap Register	MCR p15, 0, <Rt>, c10, c2, 0
NMRR, Normal Memory Remap Register	MCR p15, 0, <Rt>, c10, c2, 1
AMAIR0, Auxiliary Memory Attribute Indirection Register 0	MCR p15, 0, <Rt>, c10, c3, 0
AMAIR1, Auxiliary Memory Attribute Indirection Register 1	MCR p15, 0, <Rt>, c10, c3, 1
VBAR, Vector Base Address Register	MCR p15, 0, <Rt>, c12, c0, 0
MVBAR, Monitor Vector Base Address Register	MCR p15, 0, <Rt>, c12, c0, 1

On a reset by the external system that resets the PE into EL3 using AArch32, the **CP15SDISABLE** input signal must be taken LOW. This permits the Reset code to set up the configuration of EL3 features. When the input is asserted HIGH, any attempt to write to the Secure registers shown in [Table G4-41 on page G4-4699](#) results in an Undefined Instruction exception.

The **CP15SDISABLE** input does not affect reading Secure registers, or reading or writing Non-secure registers. It is IMPLEMENTATION DEFINED how the input is changed and when changes to this input are reflected in the PE, and an implementation might not provide any mechanism for driving the **CP15SDISABLE** input HIGH. However, in an implementation in which the **CP15SDISABLE** input can be driven HIGH, changes in the state of **CP15SDISABLE** must be reflected as quickly as possible. Any change must occur before completion of an Instruction Synchronization Barrier operation, issued after the change, is visible to the PE with respect to instruction execution boundaries. Software must perform an Instruction Synchronization Barrier operation meeting the above conditions to ensure all subsequent instructions are affected by the change to **CP15SDISABLE**.

When EL3 is using AArch32, use of **CP15SDISABLE** means key Secure features that are accessible only at PL1 can be locked in a known state. This provides an additional level of overall system security. ARM expects control of **CP15SDISABLE** to reside in the system, in a block dedicated to security.

Access to registers from Monitor mode

When the PE is in Monitor mode, the PE is in Secure state regardless of the value of the **SCR.NS** bit. In Monitor mode, the **SCR.NS** bit determines whether, for System registers in the (coproc==0b1111) encoding space, valid uses of the MRC, MCR, MRRC and MCRR instructions access the Secure Banked System registers or the Non-secure Banked System registers. That is, when:

NS == 0 Common, Restricted access, and Secure Banked System registers are accessed by MRC, MCR, MRRC and MCRR instructions that target the (coproc==0b1111) encoding space.

If the implementation includes EL2, the registers listed in [Hyp mode read/write registers in the \(coproc==0b1111\) encoding space on page G4-4695](#) and [Hyp mode encodings for shared \(coproc==0b1111\) System registers on page G4-4696](#) are not accessible, and any attempt to access them generates an Undefined Instruction exception.

———— **Note** ————

The operations listed in [Hyp mode \(coproc==0b1111\) write-only System instructions on page G4-4697](#) are accessible in Monitor mode regardless of the value of **SCR.NS**.

System instructions in the (coproc==0b1111) encoding space use the Security state to determine all resources used, that is, all operations performed by these instructions are performed in Secure state.

NS == 1 Common, Restricted access and Non-secure Banked System registers are accessed by MRC, MCR, MRRC and MCRR instructions that target the (coproc==0b1111) encoding space.

If the implementation includes EL2, all the registers and operations listed in the subsections of [EL2-mode System registers on page G4-4695](#) are accessible, using the MRC, MCR, MRRC, or MCRR instructions required to access them from Hyp mode.

System instructions in the (coproc==0b1111) encoding space use the Security state to determine all resources used, that is, all operations by these instructions are performed in Secure state.

The Security state determines whether the Secure or Non-secure Banked registers determine the control state.

———— **Note** ————

Where the contents of a register select the value accessed by an MRC or MCR access to a different register, then the register that is used for selection is being used as control state. For example, **CSSELR** selects the current **CCSIDR**, and therefore **CSSELR** is used as control state. Therefore, in Monitor mode:

- **SCR.NS** determines whether the Secure or Non-secure **CSSELR** is accessible.
- Because the PE is in Secure state, the Secure **CSSELR** selects the current **CCSIDR**.

G4.14.3 Fixed values in register diagrams

In register diagrams, a fixed bit can be indicated by one of 0, (0), 1, or (1), with the following meanings:

- 0** In any implementation:
 - The bit must read as 0.
 - Writes to the bit must be ignored.
 - Software:
 - Can rely on the bit reading as 0.
 - Must use an SBZP policy to write to the bit.
- (0)** The bit should-be-zero. In AArch32 state there are a small number of cases where a bit is (0) in some contexts, and has a different defined behavior in other contexts. See [RES0](#).
- 1** In any implementation:
 - The bit must read as 1.
 - Writes to the bit must be ignored.
 - Software:
 - Can rely on the bit reading as 1.
 - Must use an SBOP policy to write to the bit.
- (1)** The bit is should-be-one. In AArch32 state there are a small number of cases where a bit is (1) in some contexts, and has a different defined behavior in other contexts. See [RES1](#).

———— **Note** —————

In register diagrams, (0) is a synonym for RES0, and (1) is a synonym for RES1, where RES0 and RES1 are defined in the [Glossary](#). However, when used in an instruction encoding diagram, (0) and (1) have the narrower definition that behavior is UNPREDICTABLE or CONSTRAINED UNPREDICTABLE if either:

- A bit marked as (0) has the value 1.
- A bit marked as (1) has the value 0.

—————

G4.14.4 Principles of the ID scheme for fields in ID registers

The ARM architecture specifies a number of *ID registers* that are characterized as comprising a set of 4-bit *ID fields*. Each ID field identifies the presence, and possibly the level of support for, a particular feature in an implementation of the architecture. These fields follow an architectural model that aids their use by software and provides future compatibility. This section describes that model. [AArch32 ID registers to which this scheme applies on page G4-4702](#) identifies the set of ID registers that are accessible from AArch32 state.

———— **Note** —————

These fields are distinct from register fields that enumerate the number of resources, such as the number of breakpoints, watchpoints, or performance monitors, or the amount of memory.

—————

———— **Note** —————

The presence of an ID register field for a feature does not imply that the feature is optional.

—————

To provide forward compatibility, software can rely on the features of these fields that are described in this section.

The ID fields, which are either signed or unsigned, use increasing numerical values to indicate increases in functionality. Therefore, if a value of 0x1 indicates the presence of some instructions, then the value 0x2 will indicate the presence of those instructions plus some additional instructions or functionality. This means software can be written in the form:

```
if (value >= number) {
    // do something that relies on the value of the feature
}
```

For ID fields where the value 0x0 defines that a feature is not present, the field holds an unsigned value. This covers the vast majority of such fields.

In a few cases, the architecture has been changed to permit implementations to exclude a feature that has previously been required and for which no ID field has been defined. In these cases, a new ID field is defined and:

- The field holds a signed value.
- The field value 0xF indicates that the feature is not implemented.
- The field value 0x0 indicates that the feature is implemented.
- Software that depends on the feature can use the test:

```
if value >= 0 {  
    // Software features that depend on the presence of the hardware feature  
}
```

In some cases, it has been decided retrospectively that the increase in functionality between two consecutive numerical values is too great, and it is desirable to permit an intermediate degree of functionality, and the means to discover this. This is done by the introduction of a *fractional* field that both:

- Is referred to in the definition of the original field.
- Applies only when the original field is at the lower value of the step.

In principle a fractional field can be used for two different fractional steps, with different meanings associated with each of these steps. For this reason, a fractional field must be interpreted in the context of the field to which it relates and the value of that field. [Example G4-6](#) shows the use of such a field.

Example G4-6 Example of the use of a fractional field

For a field describing some class of functionality:

- The value 0x1 was defined as indicating that item A is present.
- The value 0x2 was defined as indicating that items B and C are present, in addition to item A.

Subsequently, it might be necessary to introduce a second ID field to indicate that A and B only are present. This new field is a fractional field, and might be defined as having the value 0x1 when A and B only are present. This fractional field is valid only when the original ID field has the value 0x1.

This approach means that:

- Software that depends on the test if (value >= 0x2) can rely on features A, B, and C being present,
- Software that depends on the test if (value >= 0x1) can rely on feature A being present.
- If new software needs to check only that features A and B are present then it can test:

```
if (value >= 0x2 || (value == 0x1 && fractional_value >= 0x1)) {  
    // Software features that depend on A and B only  
}
```

A fractional field uses the same approach of increasing numerical values indicating increasing functionality, and the fractional approach can also be applied recursively to fractional fields.

Unused ID fields, and fractional fields that are not applicable, are RES0 to allow their future use when features, or fractional implementation options, are added.

AArch32 ID registers to which this scheme applies

This scheme applies to the following AArch32 system registers:

- The Auxiliary Feature register [ID_AFR0](#).
- The Processor Feature registers [ID_PFR0](#) and [ID_PFR1](#).
- The Debug Feature register [ID_DFR0](#).
- The Memory Model Feature registers [ID_MMFR0](#), [ID_MMFR1](#), [ID_MMFR2](#), [ID_MMFR3](#), and [ID_MMFR4](#).

- The Instruction Set Attribute registers [ID_ISAR0](#), [ID_ISAR1](#), [ID_ISAR2](#), [ID_ISAR3](#), [ID_ISAR4](#), and [ID_ISAR5](#).
- The Media and VFP Feature registers [MVFR0](#), [MVFR1](#), and [MVFR2](#).

———— **Note** —————

Principles of the ID scheme for fields in ID registers on page D7-2195 includes information about the AArch64 System registers and the memory-mapped registers to which this scheme applies.

G4.15 VMSAv8-32 organization of registers in the (coproc==0b1110) encoding space

The System registers in the (coproc==0b1110) encoding space provide a number of distinct control functions, covering:

- Debug.
- Trace.
- Execution environment control, for identification of the trivial Jazelle implementation.

Because these functions are distinct, the descriptions of these registers are distributed, as follows:

- In this manual [Debug registers on page G6-5239](#) describes the Debug registers.
- [The Embedded Trace Macrocell Architecture Specification](#) describes the Trace registers.

This section summarizes the allocation of the System registers in the (coproc==0b1110) encoding space between these different functions, and the register encodings in this space that are reserved.

The 32-bit System register encodings are classified by the {opc1, CRn, opc2, CRm} values required to access them using an MCR or an MRC instruction. The 64-bit System register encodings are classified by the {opc1, CRm} values required to access them using an MCRR or an MRRC instruction. For the registers in the (coproc==0b1110) encoding space, the opc1 value determines the primary allocation of these registers, as follows:

opc1==0 Debug registers.

opc1==1 Trace registers.

opc1==7 Jazelle registers. Jazelle registers are implemented as required for a trivial Jazelle implementation.

Other opc1 values

Reserved.

———— Note ————

Primary allocation of (coproc==0b1110) register function by opc1 value differs from the allocation of (coproc==0b1111) registers, where primary allocation is by CRn value for 32-bit register accesses, or CRm value for 64-bit register accesses.

For the Debug and Jazelle registers, [Table G4-42 on page G4-4705](#) defines:

- The {opc1, CRn, opc2, CRm} values used for accessing the 32-bit registers using the MRC and MCR instructions.
- The {opc1, CRm} values used for accessing the 64-bit register using the MRRC instruction.

Some Debug registers can also be accessed using the LDC and STC instructions. [Table G4-43 on page G4-4706](#) defines the CRn values used for accessing the registers using these instructions.

———— Note ————

The only permitted uses of the LDC and STC instructions are:

- An LDC access to load data from memory to [DBGDTRXint](#).
- An STC access to store data to memory from [DBGDTRRXint](#).

In the LDC and STC syntax descriptions in this Manual, the required coproc value of p14 and CRn value of c5 are given explicitly.

G4.15.1 Register access instruction arguments, (coproc==0b1110) registers

Table G4-42 shows the MCR, MRC, and MRRC instruction arguments required for accesses to each register that can be visible in the System register interface in the (coproc==0b1110) encoding.

Table G4-42 Mapping of (coproc==0b1110) MCR, MRC, and MRRC instruction arguments to System registers

opc1	CRn	opc2	CRm	Name	Width	Description		
0	c0	0	c0	DBGDIDR	32-bit	Debug ID, or unallocated ^a

1	c0-c7	0-7	c0-c15	-	32-bit	Reserved for OPTIONAL Trace extension
7	c0	0	c0	JIDR	32-bit	Jazelle ID Register ^c
	c1	0	c0	JOSCR	32-bit	Jazelle OS Control Register ^c
	c2	0	c0	JMCR	32-bit	Jazelle Main Configuration Register ^c
All other encodings				-	32-bit	Unallocated

- a. If EL1 cannot use AArch32 this register is OPTIONAL and deprecated. See the register description for details.
- b. Not implemented breakpoint and watchpoint register access instructions are unallocated. If EL2 is not implemented or breakpoint *n* is not context-aware, [DBGXVR<n>](#) is unallocated. CRm encodes <*n*>, the breakpoint or watchpoint number.
- c. Legacy register, see [Legacy feature registers, functional group on page G4-4744](#).

[Table G4-43](#) shows the LDC and STC instruction arguments required for accesses to the Debug registers that can be accessed using these instructions.

Table G4-43 Mapping of LDC and STC instruction arguments to System registers

CRn	Instruction	Name	Width	Description
c5	LDC	DBGDTRTXint	32-bit	Debug Data Transfer Register, Transmit, Internal View
c5	STC	DBGDTRRXint	32-bit	Debug Data Transfer Register, Receive, Internal View

———— **Note** —————

In the instruction syntax descriptions for the LDC and STC instructions, the required coproc and CRn values are given explicitly as coproc==p14, CRn==c5.

G4.16 VMSAv8-32 organization of registers in the (coproc==0b1111) encoding space

For 32-bit accesses to the System registers in the (coproc==0b1111) encoding space, the ordered set of parameters {CRn, opc1, CRm, opc2} determine the register order. Within this ordering, the CRn value originally provided a functional grouping of these registers. As the number of System registers has increased this ordering has become less appropriate.

This document now:

- Groups the ARMv8.0 System registers in the (coproc==0b1111) encoding space by functional group, see [Functional grouping of VMSAv8-32 System registers on page G4-4726](#).
- Describes all of the ARMv8.0 System registers for VMSAv8-32, in [Chapter G6 AArch32 System Register Descriptions](#).
- Gives additional information about the organization of the VMSAv8-32 System registers in the (coproc==0b1111) encoding space, in the remainder of this section.

Note

Not all System registers introduced by architectural extensions to ARMv8.0 are described in [Chapter G6 AArch32 System Register Descriptions](#). For information about the System registers introduced by architectural extensions to ARMv8.0, see [ARMv8 architecture extensions on page A1-55](#).

This section presents information as follows:

Register ordering by {CRn, opc1, CRm, opc2}

See:

- [System register summary for \(coproc==0b1111\) encodings by CRn value on page G4-4708](#).
- [Full list of VMSAv8-32 System registers in the \(coproc==0b1111\) encoding space on page G4-4710](#).

Note

The ordered listing of (coproc==0b1111) registers by the {CRn, opc1, CRm, opc2} encoding of the 32-bit registers is most likely to be useful to those implementing AArch32 state, and to those validating such implementations. However, otherwise, the grouping of registers by function is more logical.

Views of the registers, that depend on the current state of the PE

See [AArch32 views of the System registers in the \(coproc==0b1111\) encoding space on page G4-4723](#).

Note

The different register views are particularly significant in implementations that include EL2.

In addition, the indexes in [Appendix K11 Registers Index](#) include all of the System registers.

G4.16.1 System register summary for (coproc==0b1111) encodings by CRn value

Figure G4-19 summarizes the grouping of the System registers in the (coproc==0b1111) encoding space, for a VMSAv8-32 implementation, by the value of CRn used for a 32-bit access to the register.

Figure G4-19 System register groupings for (coproc==0b1111), for 32-bit registers

Note

For the System registers in the (coproc==0b1111) encoding space, Figure G4-19 gives only an overview of the assigned encodings for 32-bit registers for each of the CRn values c0-c15. For more information, see:

- The full list of registers in the (coproc==0b1111) encoding space, in *Full list of VMSAv8-32 System registers in the (coproc==0b1111) encoding space* on page G4-4710, for the definition of the assigned and unassigned encodings for that register.
- The register definitions in *Chapter G6 AArch32 System Register Descriptions* for any dependencies on the implemented Exception levels.

In general, System register accesses using an unallocated set of {CRn, opc1, CRm, opc2} values are UNDEFINED. *Behavior of VMSAv8-32 32-bit System registers with (coproc==0b1111, CRn==c0)* on page G4-4709 described the only exceptions to this rule.

The 32-bit System registers with (coproc==0b1111, CRn==c15), and the corresponding 64-bit System registers, are reserved for implementation defined registers. For more information see *Reserved encodings in the VMSAv8-32 System register (coproc==0b1111) space* on page G4-4709.

The HSTR.Tn trap on (coproc==0b1111) System registers

As *General trapping to Hyp mode of Non-secure EL0 and EL1 accesses to System registers in the (coproc==0b1111) encoding space* on page G1-4440 describes, when the value of HSTR.Tn is 1, Non-secure PL1 accesses to System registers in the (coproc==0b1111) encoding space using a CRn or CRm value that corresponds to the value of Tn are trapped to PL2, even if the encoding is UNDEFINED when the value of HSTR.Tn is 0. This rule applies:

- For 32 bit register accesses when the value of Rn in the MCR or MRC instruction corresponds to Tn.
- For 64 bit register accesses when the value of Rm in the MCRR or MRRC instruction corresponds to Tn.

If there are matching System register encodings that are accessible from Non-secure PL0 then those accesses are also trapped to PL2 when the value of HSTR.Tn is 1.

Behavior of VMSAv8-32 32-bit System registers with (coproc==0b1111, CRn==c0)

In the (coproc==0b1111) encoding space, the 32-bit System registers with (CRn==c0) provide device and feature identification. That is, they provide registers in the functional group described in *Identification registers, functional group* on page G4-4727.

Table G4-44 on page G4-4711 shows all of the architecturally required System registers with {coproc==0b1111, CRn==c0}. The behavior of 32-bit System register encodings in this group that are not shown in the table, and encodings that are part of an unimplemented Exception level, depends on the value of opc1, and possibly on the value of CRm and opc2, as follows:

- opc1 == 0 All write accesses to the encodings are UNDEFINED.
For read accesses:
- The following encodings return an UNKNOWN value:
 - CRm==3, opc2=={0, 1, 2}.
 - CRm=={4, 6, 7}, opc2=={0, 1}.
 - CRm==5, opc2=={0, 1, 4, 5}.
 - All other encodings are RES0.
- opc1 > 0 All accesses to the encodings are UNDEFINED.

See also *Accesses to unallocated encodings in the (coproc==0b111x) encoding space* on page G6-4765.

———— Note ————

Some of these registers were previously described as being part of the CPUID identification scheme, see *The CPUID identification scheme* on page G4-4728.

Reserved encodings in the VMSAv8-32 System register (coproc==0b1111) space

AArch32 state reserves a number of regions in the (coproc==0b1111) encoding space for IMPLEMENTATION DEFINED System registers. These reservations are defined in terms of the encoding of 32-bit accesses to the System register encoding space. That is, they are defined by the reserved 32-bit {CRn, opc1, CRm, opc2} encodings.

In ARMv8, reserved encodings that do not have an IMPLEMENTATION DEFINED function are UNDEFINED.

The following subsections give more information about these reserved encodings:

- Reserved 32-bit encodings with {coproc==0b1111, CRn==c9}.*
- Reserved 32-bit encodings with {coproc==0b1111, CRn==c10} on page G4-4710.*
- Reserved 32-bit encodings with {coproc==0b1111, CRn==c11} on page G4-4710.*
- Reserved 32-bit encodings with {coproc==0b1111, CRn==c15} on page G4-4710.*

Reserved 32-bit encodings with {coproc==0b1111, CRn==c9}

In the AArch32 encoding space, for 32-bit encodings with {coproc==0b1111, CRn==c9}, the following encodings are reserved for IMPLEMENTATION DEFINED purposes:

- Encodings with {coproc==0b1111, CRn==c9, opc=={0-7}, CRm=={c0-c2, c5-c8}} are reserved for IMPLEMENTATION DEFINED branch predictor, cache, and TCM operations.
- Encodings with {coproc==0b1111, CRn==c9, opc=={0-7}, CRm==c15} are reserved for IMPLEMENTATION DEFINED performance monitors.

———— Note ————

These are distinct from the OPTIONAL ARM Performance Monitors Extension, the registers for which use the encoding space {coproc==0b1111, CRn==c9, opc=={0-7}, CRm=={c12-c14}}.

Reserved 32-bit encodings with {coproc==0b1111, CRn==c10}

In the AArch32 encoding space, for 32-bit encodings with {coproc==0b1111, CRn==c10}, the following encodings are reserved for IMPLEMENTATION DEFINED purposes:

- Encodings with {coproc==0b1111, CRn==c10, opc=={0-7}, CRm=={c0, c1, c4, c8}} are reserved for IMPLEMENTATION DEFINED TLB lockdown operations.

Reserved 32-bit encodings with {coproc==0b1111, CRn==c11}

In the AArch32 encoding space, for 32-bit encodings with {coproc==0b1111, CRn==c11}, the following encodings are reserved for IMPLEMENTATION DEFINED purposes:

- Encodings with {coproc==0b1111, CRn==c11, opc=={0-7}, CRm=={c0-c8, c15}} are reserved for IMPLEMENTATION DEFINED DMA operations for TCM access.

In ARMv8, the remainder of the AArch32 {coproc==0b1111, CRn==c11} encoding space is UNDEFINED.

Reserved 32-bit encodings with {coproc==0b1111, CRn==c15}

ARMv8 reserves the AArch32 System register encodings with (coproc==0b1111, CRn==c15) for IMPLEMENTATION DEFINED purposes, and does not impose any restrictions on the use of these encodings. The documentation of the ARM implementation must describe fully any registers implemented in the {coproc==0b1111, CRn==c15} encoding space. Normally, for processor implementations by ARM, this information is included in the *Technical Reference Manual* for the processor.

Typically, an implementation uses the {coproc==0b1111, CRn==c15} encodings to provide test features, and any required configuration options that are not covered by this Manual.

This reservation means that the AArch32 64-bit encodings with {coproc==0b1111, CRm==c15} are also reserved for IMPLEMENTATION DEFINED purposes, without any restrictions on the use of these encodings.

G4.16.2 Full list of VMSAv8-32 System registers in the (coproc==0b1111) encoding space

Table G4-44 on page G4-4711 shows the System registers in the (coproc==0b1111) encoding space in VMSAv8-32, in the order of the {CRn, opc1, CRm, opc2} parameter values used in MCR or MRC accesses to the 32-bit registers:

- For MCR or MRC accesses to the 32-bit registers, CRn is the primary identifier of the target System register for the access. This rule applies, also, to MCR or MRC instructions that provide 32-bit accesses to a single word of a 64-bit System register.
- For MCRR or MRRC accesses to the 64-bit registers, CRm is the primary identifier of the target System register for the access. Table G4-44 on page G4-4711 orders the 64-bit registers with the 32-bit registers accessed using the same primary register identifier. For example, the 64-bit encoding of TTBR0, that is accessed with (CRm==c2), is listed with the 32-bit registers that are accessed with (CRn==c2).

-	6	c14	-	CNTHP_CVAL	64-bit	EL2 Physical Timer CompareValue register
c15	0-7	c0-c15	0-7	-	32-bit	See <i>Reserved 32-bit encodings with {coproc==0b1111, CRn==c15}</i> on page G4-4710

- a. [REVIDR](#) is an optional register. If it is not implemented, the encoding with opc2 set to 6 is an alias of [MIDR](#).
- b. Implemented only as part of EL2, when EL2 is using AArch32. Otherwise, encoding is unallocated and CONSTRAINED UNPREDICTABLE, see *Accesses to unallocated encodings in the (coproc==0b111x) encoding space on page G6-4765*.
- c. Implemented only as part of the EL3, when EL3 is using AArch32. Otherwise, as described in *Accesses to unallocated encodings in the (coproc==0b111x) encoding space on page G6-4765*, encoding is unallocated and:
- UNDEFINED, for the registers accessed using CRn set to c12.
 - CONSTRAINED UNPREDICTABLE, for the register accessed using CRn values other than c12.
- d. Introduced in ARMv8.
- e. Introduced in ARMv8. Implemented only if the implementation includes the GIC System registers. For information see *Generic Interrupt Controller System registers, functional groups on page G4-4740*. As that subsection describes, each ICV_* register uses the same encoding as the corresponding ICC_* register
- f. This register is only accessible in Debug state.
- g. *RAS System registers, see The Reliability, Availability, and Serviceability (RAS) Extension on page A1-63.*

- h. For performance reasons, ARM deprecates any use of these memory barrier operations.
- i. When an implementation is using the Long descriptor translation table format these encodings access the [MAIRO](#) and [MAIR1](#) registers. Otherwise, they access the [PRRR](#) and [NMRR](#).
- j. Introduced in ARMv8. Only one of [RMR](#) and [HRMR](#) is implemented, corresponding to the highest implemented Exception level, and the register is implemented only if that Exception level is using AArch32.
- k. Implemented as part of the Generic Timer.
- l. Implemented as RW as part of the Generic Timer on an implementation that includes EL2 and when EL2 is using AArch32. For more information see [Status of the CNTVOFF register on page G5-4757](#).

G4.16.3 AArch32 views of the System registers in the (coproc==0b1111) encoding space

The following sections summarize the different software views of the System registers in the (coproc==0b1111) encoding space, for VMSAv8-32:

- [PL0 views of the System registers in the \(coproc==0b1111\) encoding space.](#)
- [PL1 views of the System registers in the in the \(coproc==0b1111\) encoding space on page G4-4725.](#)
- [Non-secure PL2 view of the System registers in the \(coproc==0b1111\) encoding space on page G4-4725.](#)

———— **Note** ————

In previous versions of the ARM architecture, the behavior of accesses to the System registers in the (coproc==0b1111) encoding space were described in relation to the PE modes. In Secure state, the Exception level of the privileged PE modes depends on whether EL3 is using AArch32, or is using AArch64. This means it is simpler to describe the views of the registers in terms of *privilege levels*, PL0-PL2, rather than the *Exception levels* EL1-EL3. This is because each AArch32 PE mode is associated with a particular privilege level, but in Secure state its Exception level can depend on the EL3 Execution state. For more information see [Security state, Exception levels, and AArch32 execution privilege on page G1-4318.](#)

PL0 views of the System registers in the (coproc==0b1111) encoding space

Software executing at PL0, unprivileged, can access only a small subset of the System registers in the (coproc==0b1111) encoding space, as [Table G4-45](#) shows. This table excludes possible PL0 access to the following registers:

- The Performance Monitors Extension, see [Possible PL0 access to the Performance Monitors Extension System registers on page G4-4724.](#)
- The Generic Timer registers, see [Possible PL0 access to the Generic Timer System registers on page G4-4724.](#)

Table G4-45 System registers in the (coproc==0b1111) encoding space accessible from PL0

Name	Access	Description	Note
CP15ISB	WO	Memory barriers on page E2-2768	ARM deprecates use of these operations
CP15DSB	WO		
CP15DMB	WO		
TPIDRURW	RW	TPIDRURW, PL0 Read/Write Software Thread ID Register on page G6-5201	-
TPIDRURO	RO	TPIDRURO, PL0 Read-Only Software Thread ID Register on page G6-5199	RW at PL1

Possible PL0 access to the Performance Monitors Extension System registers

In a VMSAv8-32 implementation that includes the Performance Monitors Extension, when using the System register interface to the Performance Monitors:

- The [PMUSERENR](#) is RO from PL0.
- When:
 - The value of [PMUSERENR.EN](#) is 1, [PMCNTENSET](#), [PMCNTENCLR](#), [PMOVSr](#), [PMSWINC](#), [PMSELR](#), [PMCEID0](#), [PMCEID1](#), [PMCCNTR](#), [PMXEVTYPER](#), [PMXEVCNTR](#), [PMUSERENR](#), [PMOVSSET](#), [PMEVCNTR<n>](#), [PMEVTYPER<n>](#), and [PMCCFILTR](#) are accessible by reads and writes from PL0.
 - The value of [PMUSERENR.ER](#) is 1, [PMXEVCNTR](#) and [PMEVCNTR<n>](#) are accessible by reads and from PL0, and [PMSELR](#) is accessible by reads and writes from PL0.
 - The value of [PMUSERENR.CR](#) is 1, [PMCCNTR](#) is accessible by reads from PL0.
 - The value of [PMUSERENR.SW](#) is 1, [PMSWINC](#) is accessible by writes from PL0.

In general, when the value of a [PMUSERENR](#).{EN, ER, CR, SW} bit is 1, the enabled registers have the same access permissions from PL0 as they do from PL1.

For more information, see:

- [Traps to EL1 of EL0 accesses to Performance Monitors registers on page D1-1850](#).
- [Chapter D5 The Performance Monitors Extension](#), in particular [Access permissions on page D5-2176](#).

Possible PL0 access to the Generic Timer System registers

In a VMSAv8-32 implementation, when using the System register interface to the Generic Timer registers:

- If [CNTKCTL.PL0PCTEN](#) is set to 1, then if the physical counter register [CNTPCT](#) is accessible from PL1 it is also accessible from PL0. For more information see [Accessing the physical counter on page D6-2184](#).
- If [CNTKCTL.PL0PVTEN](#) is set to 1, the virtual counter register [CNTVCT](#) is accessible from PL0. For more information, see [Accessing the virtual counter on page D6-2185](#).
- If at least one of [CNTKCTL](#).{[PL0PCTEN](#), [PL0PVTEN](#)} is set to 1, the [CNTFRQ](#) register is RO from PL0.
- If:
 - [CNTKCTL.PL0PTEN](#) is set to 1, the physical timer registers [CNTP_CTL](#), [CNTP_CVAL](#), and [CNTP_TVAL](#) are accessible from PL0.
 - [CNTKCTL.PL0VTEN](#) is set to 1, the virtual timer registers [CNTV_CTL](#), [CNTV_CVAL](#), and [CNTV_TVAL](#), are accessible from PL0.

For more information, see [Accessing the timer registers on page G5-4759](#).

PL1 views of the System registers in the in the (coproc==0b1111) encoding space

Software executing at PL1 can access all System registers in the (coproc==0b1111) encoding space, with the following exceptions:

Non-secure PL1 software

EL3 restricts or prevents access to some registers by Non-secure PL1 software. In particular:

- The Restricted access System registers are either not accessible to Non-secure PL1 software, or are read-only to Non-secure PL1 software, see *Restricted access System registers on page G4-4694*.
- Configuration settings determine whether Non-secure PL1 software can access the Configurable access System registers, see *Configurable access System registers on page G4-4694*.

The individual register descriptions identify these access restrictions.

In an implementation that includes EL2, Non-secure PL1 software has no visibility of the PL2-mode registers summarized in *Hyp mode read/write registers in the (coproc==0b1111) encoding space on page G4-4695*. The individual register descriptions identify these registers as EL2-mode registers.

Secure PL1 software

In general, Secure PL1 software has access to all System registers. However:

- When EL3 is using AArch32, the **CP15SDISABLE** signal disables write access to a number of Secure registers, see *The CP15SDISABLE input signal on page G4-4699*.
- The PL2-mode registers are accessible from Secure state only if EL3 is using AArch32. When this is the case, Secure PL1 software can access these registers by moving into Monitor mode, and setting **SCR.NS** to 1. *Hyp mode read/write registers in the (coproc==0b1111) encoding space on page G4-4695* summarizes these registers.

The individual register descriptions identify:

- The registers affected by the **CP15SDISABLE** signal.
- The PL2-mode registers.

Non-secure PL2 view of the System registers in the (coproc==0b1111) encoding space

Non-secure software executing at PL2 can access:

- The registers that are accessible to Non-secure software executing at PL1, as defined in *PL1 views of the System registers in the in the (coproc==0b1111) encoding space*. Access permissions for these registers are identical to those for Non-secure software executing at EL1.
- The PL2-mode registers summarized in *Hyp mode read/write registers in the (coproc==0b1111) encoding space on page G4-4695*, and described in *Virtualization registers, functional group on page G4-4730*.

G4.17 Functional grouping of VMSAv8-32 System registers

This section describes how the System registers in an VMSAv8-32 implementation divide into functional groups.

[Chapter G6 AArch32 System Register Descriptions](#) describes each of these registers.

Note

- [Table G4-44 on page G4-4711](#) lists all of the VMSAv8-32 System registers in the (coproc==0b1111) encoding space, ordered by:
 1. The CRn primary register used when using a 32-bit access to the register.
For 64-bit register accesses using an MCRR or MRRC instruction, the instruction arguments that identify the target register are {coproc, Rm, opc1}. The value of Rm determines where these registers appear in [Table G4-44 on page G4-4711](#), so that these registers appear with the 32-bit registers accessed using that value for CRn. So, for example, the 64-bit access to [TTBR0](#), that uses (CRn==c2), appears with the 32-bit access to [TTBR0](#), that uses (CRn==c2).
 2. The opc1 value used when accessing the register.
 3. For 32-bit registers, the {CRm, opc2} values used when accessing the register.
- The functional groups defined in this section mainly consist of the VMSAv8-32 System registers, but include some additional System registers.
- Some registers belong to more than one functional group.

For other related information see:

- [The AArch32 System register interface on page G1-4408](#) for general information about the access to the AArch32 System registers, including the main register access instructions MRC and MCR.
- [About the System registers for VMSAv8-32 on page G4-4689](#).
- [VMSAv8-32 organization of registers in the \(coproc==0b1110\) encoding space on page G4-4704](#).
- [VMSAv8-32 organization of registers in the \(coproc==0b1111\) encoding space on page G4-4707](#).
- [About the AArch32 System registers on page G6-4764](#).

The remainder of this chapter, and the register descriptions in [Chapter G6 AArch32 System Register Descriptions](#), assume you are familiar with these sections, and use conventions and other information from them without any explanation.

Each of the following sections summarizes a functional group of VMSAv8-32 System registers:

- [Identification registers, functional group on page G4-4727](#).
- [General system control registers, functional group on page G4-4728](#).
- [Virtual memory control registers, functional group on page G4-4729](#).

Table G4-46 Identification registers, VMSAv8-32 (continued)

Name	CRn	opc1	CRm	opc2	Width	Type	Description
TLBTR	c0	0	c0	3	32-bit	RO	TLB Type Register
VMPIDR	c0	4	c0	5	32-bit	RW	Virtualization Multiprocessor ID Register
VPIDR	c0	4	c0	5	32-bit	RW	Virtualization Processor ID Register

a. CPUID register, see [The CPUID identification scheme](#).

The other registers in this group are the [FPSID](#), [MVFR0](#), [MVFR1](#), and [MVFR2](#).

The [JIDR](#) holds legacy identification information.

The CPUID identification scheme

The ID_* registers were originally called the CPUID identification scheme registers. A footnote to [Table G4-46 on page G4-4727](#) identifies these registers. However, functionally, there is no value in separating these registers from the slightly larger Identification registers functional group.

G4.17.2 General system control registers, functional group

[Table G4-47](#) shows the VMSAv8-32 System registers in the (coproc==0b1111) encoding space that are in the General system control registers functional group.

Table G4-47 General system control registers, VMSAv8-32

Name	CRn	opc1	CRm	opc2	Width	Type	Description
ACTLR	c1	0	c0	1	32-bit	RW	Auxiliary Control Register
ACTLR2	c1	0	c0	3	32-bit	RW	Auxiliary Control Register 2
CPACR	c1	0	c0	2	32-bit	RW	Architectural Feature Access Control Register
HACTLR	c1	4	c0	0	32-bit	RW	Hyp Auxiliary System Control Register
HACTLR2	c1	4	c0	3	32-bit	RW	Hyp Auxiliary System Control Register 2
HSCTLR	c1	4	c0	0	32-bit	RW	Hyp System Control Register
SCTLR	c1	0	c0	0	32-bit	RW	System Control Register

The following sections summarize the System registers added by the corresponding Exception levels:

- [Security registers, functional group on page G4-4732](#).
- [Virtualization registers, functional group on page G4-4730](#).

G4.17.3 Virtual memory control registers, functional group

Table G4-48 shows the VMSAv8-32 System registers in the (coproc==0b1111) encoding space that are in the Virtual memory control registers functional group.

Table G4-48 Virtual memory control registers

Name	CRn	opc1	CRm	opc2	Width	Type	Description
AMAIRO	c10	0	c3	0	32-bit	RW	Auxiliary Memory Attribute Indirection Register 0
AMAIR1	c10	0	c3	1	32-bit	RW	Auxiliary Memory Attribute Indirection Register 1
CONTEXTIDR	c13	0	c0	1	32-bit	RW	Context ID Register
DACR	c3	0	c0	0	32-bit	RW	Domain Access Control Register
HAMAIRO	c10	4	c3	0	32-bit	RW	Hyp Auxiliary Memory Attribute Indirection Register 0
HAMAIR1	c10	4	c3	1	32-bit	RW	Hyp Auxiliary Memory Attribute Indirection Register 1
HMAIRO	c10	4	c2	0	32-bit	RW	Hyp Memory Attribute Indirection Register 0
HMAIR1	c10	4	c2	1	32-bit	RW	Hyp Memory Attribute Indirection Register 1
HTCR	c2	4	c0	2	32-bit	RW	Hyp Translation Control Register
HTTBR	-	4	c2	-	64-bit	RW	Hyp Translation Table Base Register
MAIRO	c10	0	c2	0	32-bit	RW	Memory Attribute Indirection Register 0
MAIR1	c10	0	c2	1	32-bit	RW	Memory Attribute Indirection Register 1
NMRR	c10	0	c2	1	32-bit	RW	Normal Memory Remap Register
PRRR	c10	0	c2	0	32-bit	RW	Primary Region Remap Register
SCTLR	c1	0	c0	0	32-bit	RW	System Control Register
TTBCR	c2	0	c0	2	32-bit	RW	Translation Table Base Control Register
TTBCR2	c2	0	c0	3	32-bit	RW	Translation Table Base Control Register 2
TTBR0	c2	0	c0	0	32-bit	RW	Translation Table Base Register 0
TTBR0	-	0	c2	-	64-bit	RW	Translation Table Base Register 0
TTBR1	c2	0	c0	1	32-bit	RW	Translation Table Base Register 1
TTBR1	-	1	c2	-	64-bit	RW	Translation Table Base Register 1
VTCTCR	c2	4	c1	2	32-bit	RW	Virtualization Translation Control Register
VTTBR	-	6	c2	-	64-bit	RW	Virtualization Translation Table Base Register

The ACTLR and, if implemented, ACTLR2, might provide additional virtual memory control.

G4.17.4 Virtualization registers, functional group

Table G4-49 shows the VMSAv8-32 System registers in the (coproc==0b1111) encoding space that are in the Virtualization registers functional group, excluding the System instructions in this group.

Table G4-49 Virtualization registers, excluding System instructions

Name	CRn	opc1	CRm	opc2	Width	Type	Description
CNTHCTL	c14	4	c1	0	32-bit	RW	Counter-timer Hyp Control register
CNTHP_CTL	c14	4	c2	1	32-bit	RW	Counter-timer Hyp Physical Timer Control register
CNTHP_CVAL	-	6	c14	-	64-bit	RW	Counter-timer Hyp Physical Compare Value register

TLBIMVALHIS^a	c8	4	c3	5	32-bit	WO	TLB Invalidate entry by MVA, Last level, Hyp mode, Inner Shareable

a. These links are to a summary of the operation, and [The scope of TLB maintenance instructions on page G4-4641](#) describes the operation.

All the encodings shown in [Table G4-49 on page G4-4730](#) and [Table G4-50](#) are unallocated and CONstrained UNPREDICTABLE on an implementation that does not include EL2, see [Accesses to unallocated encodings in the \(coproc==0b111x\) encoding space on page G6-4765](#).

G4.17.5 Security registers, functional group

Table G4-51 shows the VMSAv8-32 System registers in the (coproc==0b1111) encoding space that are in the Security registers functional group.

Table G4-51 Security registers

Name	CRn	opc1	CRm	opc2	Width	Type	Description
ICC_MCTLR^a	c12	6	c12	4	32-bit	RW	Interrupt Controller Monitor Control Register
ICC_MGRPEN1^a	c12	6	c12	7	32-bit	RW	Interrupt Controller Monitor Interrupt Group 1 Enable register
ICC_MSRE^a	c12	6	c12	5	32-bit	RW	Interrupt Controller Monitor System Register Enable register
MVBAR	c12	0	c0	1	32-bit	RW	Monitor Vector Base Address Register

Table G4-51 Security registers (continued)

Name	CRn	opc1	CRm	opc2	Width	Type	Description
NSACR	c1	0	c1	2	32-bit	RW	Non-Secure Access Control Register
RMR	c12	0	c0	2	32-bit	RW	Reset Management Register
SCR	c1	0	c1	0	32-bit	RW	Secure Configuration Register
SDER	c1	0	c1	1	32-bit	RW	Secure Debug Enable Register

a. For information about these registers see the *ARM® Generic Interrupt Controller Architecture Specification, GIC architecture version 3.0 and version 4.0*.

All the encodings shown in [Table G4-51 on page G4-4732](#) are unallocated and CONSTRAINED UNPREDICTABLE on an implementation that does not include EL3, see [Accesses to unallocated encodings in the \(coproc==0b111x\) encoding space on page G6-4765](#).

G4.17.6 Exception and fault handling registers, functional group

[Table G4-52](#) shows the VMSAv8-32 System registers in the (coproc==0b1111) encoding space that are in the Exception and fault handling registers functional group.

Table G4-52 Exception and fault handling registers

Name	CRn	opc1	CRm	opc2	Width	Type	Description
ADFSR	c5	0	c1	0	32-bit	RW	Auxiliary Data Fault Status Register
AIFSR	c5	0	c1	1	32-bit	RW	Auxiliary Instruction Fault Status Register
DFAR	c6	0	c0	0	32-bit	RW	Data Fault Address Register
DFSR	c5	0	c0	0	32-bit	RW	Data Fault Status Register
HADFSR	c5	4	c1	0	32-bit	RW	Hyp Auxiliary Data Fault Status Register
HAIFSR	c5	4	c1	1	32-bit	RW	Hyp Auxiliary Instruction Fault Status Register
HDFAR	c6	4	c0	0	32-bit	RW	Hyp Data Fault Address Register
HIFAR	c6	4	c0	2	32-bit	RW	Hyp Instruction Fault Address Register
HPFAR	c6	4	c0	4	32-bit	RW	Hyp IPA Fault Address Register
HSR	c5	4	c2	0	32-bit	RW	Hyp Syndrome Register
HVBAR	c12	4	c0	1	32-bit	RW	Hyp Vector Base Address Register
IFAR	c6	0	c0	2	32-bit	RW	Instruction Fault Address Register
IFSR	c5	0	c0	1	32-bit	RW	Instruction Fault Status Register
ISR	c12	0	c1	0	32-bit	RO	Interrupt Status Register
MVBAR	c12	0	c0	1	32-bit	RW	Monitor Vector Base Address Register
RVBAR	c12	0	c0	1	32-bit	RW	Reset Vector Base Address Register
VBAR	c12	0	c0	0	32-bit	RW	Vector Base Address Register

The PE returns fault information using the fault status registers and the fault address registers. For details of how these registers are used see [Exception reporting in a VMSAv8-32 implementation on page G4-4663](#).

———— **Note** ————

These registers also report information about debug exceptions. For more information see:

- [Data Abort exceptions, taken to a PL1 mode on page G4-4665.](#)
- [Prefetch Abort exceptions, taken to a PL1 mode on page G4-4667.](#)
- [Reporting exceptions taken to Hyp mode on page G4-4673.](#)

G4.17.7 Reset management registers, functional group

Table G4-53 shows the VMSAv8-32 System registers in the (coproc==0b1111) encoding space that are in the Reset management registers functional group.

Table G4-53 Reset management registers

Name	CRn	opc1	CRm	opc2	Width	Type	Description
HRMR	c12	4	c0	2	32-bit	RW	Hyp Reset Management Register
RMR	c12	0	c0	2	32-bit	RW	Reset Management Register

G4.17.8 Thread and process ID registers, functional group

Table G4-54 shows the VMSAv8-32 System registers in the (coproc==0b1111) encoding space that are in the Thread and process ID registers functional group.

Table G4-54 VMSAv8-32 Thread and process ID registers

Name	CRn	opc1	CRm	opc2	Width	Type ^a	Description
HTPIDR^b	c13	4	c0	2	32-bit	RW	Hyp Software Thread ID Register
TPIDRPRW	c13	0	c0	4	32-bit	RW	PL1 Software Thread ID Register
TPIDRURO	c13	0	c0	3	32-bit	RW, PL0	PL0 Read-Only Software Thread ID Register
TPIDRURW	c13	0	c0	2	32-bit	RW, PL0	PL0 Read/Write Software Thread ID Register

- PL0 in a Type description indicates that the encoding is accessible by software executing at PL0. See the register description for more information.
- Implemented only as part of EL2. Otherwise, encoding is unallocated and CONSTRAINED UNPREDICTABLE, see [Accesses to unallocated encodings in the \(coproc==0b111x\) encoding space on page G6-4765.](#)

G4.17.9 Cache maintenance instructions, functional group

Table G4-55 shows the VMSAv8-32 System instructions in the (coproc==0b1111) encoding space that are in the Cache and branch predictor maintenance instructions functional group.

Table G4-55 Cache and branch predictor maintenance instructions

Name	CRn	opc1	CRm	opc2	Width	Type	Description	Limits ^a
BPIALL^b	c7	0	c5	6	32-bit	WO	Branch predictor invalidate all	-
BPIALLIS^b	c7	0	c1	6	32-bit	WO	Branch predictor invalidate all	IS
BPIMVA^b	c7	0	c5	7	32-bit	WO	Branch predictor invalidate by VA	-
DCCIMVAC^b	c7	0	c14	1	32-bit	WO	Data cache clean and invalidate by VA	PoC

Table G4-55 Cache and branch predictor maintenance instructions (continued)

Name	CRn	opc1	CRm	opc2	Width	Type	Description	Limits ^a
DCCISW^b	c7	0	c14	2	32-bit	WO	Data cache clean and invalidate by set/way	-
DCCMVAC^b	c7	0	c10	1	32-bit	WO	Data cache clean by VA	PoC
DCCMVAU^b	c7	0	c11	1	32-bit	WO	Data cache clean by VA	PoU
DCCSW^b	c7	0	c10	2	32-bit	WO	Data cache clean by set/way	-
DCIMVAC^b	c7	0	c6	1	32-bit	WO	Data cache invalidate by VA	PoC
DCISW^b	c7	0	c6	2	32-bit	WO	Data cache invalidate by set/way	-
ICIALLU^b	c7	0	c5	0	32-bit	WO	Instruction cache invalidate all	PoU
ICIALLUIS^b	c7	0	c1	0	32-bit	WO	Instruction cache invalidate all	PoU, IS
ICIMVAU^b	c7	0	c5	1	32-bit	WO	Instruction cache invalidate by VA	PoU

- a. PoU = to Point of Unification, PoC = to Point of Coherency, IS = Inner Shareable.
b. The links in this column are to a summary of the operation, see [AArch32 cache and branch predictor maintenance instructions on page G3-4535](#).

G4.17.10 TLB maintenance instructions, functional group

Table G4-56 shows the VMSAv8-32 System instructions in the (coproc==0b1111) encoding space that are in the TLB maintenance instructions functional group. *The scope of TLB maintenance instructions on page G4-4641* describes the operations.

Table G4-56 TLB maintenance instructions

Name ^a	CRn	opc1	CRm	opc2	Width	Type	Description	Limits ^b
DTLBIALL^c	c8	0	c6	0	32-bit	WO	Invalidate entire data TLB	-
DTLBIASID^c	c8	0	c6	2	32-bit	WO	Invalidate data TLB by ASID	-
DTLBMVA^c	c8	0	c6	1	32-bit	WO	Invalidate data TLB entry by VA	-
ITLBIALL^c	c8	0	c5	0	32-bit	WO	Invalidate entire instruction TLB	-

TLBIMVALH	c8	4	c7	5	32-bit	WO	TLB Invalidate entry by MVA, Last level, Hyp mode	-
TLBIMVALHIS	c8	4	c3	5	32-bit	WO	TLB Invalidate entry by MVA, Last level, Hyp mode, Inner Shareable	IS
TLBIMVALIS	c8	0	c3	5	32-bit	WO	TLB Invalidate entry by MVA, Last level	IS

- a. These links are to a summary of the operation, and [The scope of TLB maintenance instructions on page G4-4641](#) describes the operation.
- b. IS = Inner Shareable.
- c. Deprecated. ARM deprecates use of operations that operate only on an Instruction TLB, or only on a Data TLB.
- d. The mnemonics for the operations with CRm==c7, opc2=={0, 1, 2} were previously UTLBIALL, UTLBIMVA and UTLBIMASID.

G4.17.11 Address translation instructions, functional group

Table G4-57 shows the VMSAv8-32 System instructions in the (coproc==0b1111) encoding space that are in the Address translation instructions functional group.

Table G4-57 Address translation instructions

Name	CRn	opc1	CRm	opc2	Width	Type	Description
ATS12NSOPR ^{a, c}	c7	0	c8	4	32-bit	WO	Stages 1 and 2 Non-secure only EL1 read
ATS12NSOPW ^{a, c}	c7	0	c8	5	32-bit	WO	Stages 1 and 2 Non-secure only EL1 write
ATS12NSOUR ^{a, c}	c7	0	c8	6	32-bit	WO	Stages 1 and 2 Non-secure only unprivileged read
ATS12NSOUW ^{a, c}	c7	0	c8	7	32-bit	WO	Stages 1 and 2 Non-secure only unprivileged write
ATS1CPR ^c	c7	0	c8	0	32-bit	WO	Stage 1 Current state EL1 read
ATS1CPW ^c	c7	0	c8	1	32-bit	WO	Stage 1 Current state EL1 write
ATS1CUR ^c	c7	0	c8	2	32-bit	WO	Stage 1 Current state unprivileged read
ATS1CUW ^c	c7	0	c8	3	32-bit	WO	Stage 1 Current state unprivileged write
ATS1HR ^{b, c}	c7	4	c8	0	32-bit	WO	Stage 1 Hyp mode read
ATS1HW ^{b, c}	c7	4	c8	1	32-bit	WO	Stage 1 Hyp mode write
PAR	c7	0	c4	0	32-bit	RW	Physical Address Register
	-	0	c7	-	64-bit	RW	

- a. Implemented only as part of EL3. Otherwise, encoding is unallocated and CONSTRAINED UNPREDICTABLE, see [Accesses to unallocated encodings in the \(coproc==0b111x\) encoding space on page G6-4765](#).
- b. Implemented only as part of EL2. Otherwise, encoding is unallocated and CONSTRAINED UNPREDICTABLE, see [Accesses to unallocated encodings in the \(coproc==0b111x\) encoding space on page G6-4765](#).
- c. These links are to a summary of the operation.

[Address translation instructions on page G4-4682](#) describes these operations.

G4.17.12 Lockdown, DMA, and TCM features, functional group

Table G4-58 shows the VMSAv8-32 reserved encodings in the (coproc==0b1111) encoding space that provide the Lockdown, DMA, and TCM features registers functional group.

Table G4-58 Lockdown, DMA, and TCM features, VMSAv8-32

Name	CRn	opc1	CRm	Width	opc2	Type	Description
IMPLEMENTATION DEFINED	c9	0-7	c0-c2	32-bit	0-7	a	Reserved for IMPLEMENTATION DEFINED branch predictor, cache, and TCM operations.
			c5-c8	32-bit	0-7	a	
	c10	0-7	c0-c1	32-bit	0-7	a	Reserved for IMPLEMENTATION DEFINED TLB lockdown operations
			c4	32-bit	0-7	a	
c8			32-bit	0-7	a		
c11	0-7	c0-c8	32-bit	0-7	a	Reserved for IMPLEMENTATION DEFINED DMA operations to and from TCMs	
		c15	32-bit	0-7	a		

a. Access depends on the register or operation, and is IMPLEMENTATION DEFINED.

G4.17.13 Performance Monitors Extension registers, functional group

Table G4-59 shows the VMSAv8-32 System registers in the (coproc==0b1111) encoding space that are the Performance Monitors Extension registers functional group. See also *IMPLEMENTATION DEFINED performance monitors* on page G4-4739.

Table G4-59 Performance Monitors Extension registers

Name	CRn	opc1	CRm	opc2	Width	Description
PMCCFILTR	c14	0	c15	7	32-bit	Performance Monitors Cycle Count Filter Register
PMCCNTR	c9	0	c13	0	32-bit	Performance Monitors Cycle Count Register
PMCEID0	c9	0	c12	6	32-bit	Performance Monitors Common Event Identification register 0
PMCEID1	c9	0	c12	7	32-bit	Performance Monitors Common Event Identification register 1
PMCNTENCLR	c9	0	c12	2	32-bit	Performance Monitors Count Enable Clear register
PMCNTENSET	c9	0	c12	1	32-bit	Performance Monitors Count Enable Set register
PMCR	c9	0	c12	0	32-bit	Performance Monitors Control Register
PMEVCNTR<n>, for n==0 to 7	c14	0	c8	0-7	32-bit	Performance Monitors Event Count Registers, 0-7
PMEVCNTR<n>, for n==16 to 23	c14	0	c10	0-7	32-bit	Performance Monitors Event Count Registers, 16-23
PMEVCNTR<n>, for n==24 to 30	c14	0	c11	0-6	32-bit	Performance Monitors Event Count Registers, 24-30
PMEVCNTR<n>, for n==8 to 15	c14	0	c9	0-7	32-bit	Performance Monitors Event Count Registers, 8-15

Table G4-59 Performance Monitors Extension registers (continued)

Name	CRn	opc1	CRm	opc2	Width	Description
PMEVTYPER<n> , for n==0 to 7	c14	0	c12	0-7	32-bit	Performance Monitors Event Type Registers, 0-7
PMEVTYPER<n> , for n==16 to 23	c14	0	c14	0-7	32-bit	Performance Monitors Event Type Registers, 16-23
PMEVTYPER<n> , for n==17 to 30	c14	0	c15	0-6	32-bit	Performance Monitors Event Type Registers, 24-30
PMEVTYPER<n> , for n==8 to 15	c14	0	c13	0-7	32-bit	Performance Monitors Event Type Registers, 8-15
PMINTENCLR	c9	0	c14	2	32-bit	Performance Monitors Interrupt Enable Clear register
PMINTENSET	c9	0	c14	1	32-bit	Performance Monitors Interrupt Enable Set register
PMOVSr	c9	0	c12	3	32-bit	Performance Monitors Overflow Flag Status Register
PMOVSSET	c9	0	c14	3	32-bit	Performance Monitors Overflow Flag Status Set register
PMSELR	c9	0	c12	5	32-bit	Performance Monitors Event Counter Selection Register
PMSWINC	c9	0	c12	4	32-bit	Performance Monitors Software Increment register
PMUSERENR	c9	0	c14	0	32-bit	Performance Monitors User Enable Register
PMXEVCNTR	c9	0	c13	2	32-bit	Performance Monitors Event Count Register
PMXEVTYPER	c9	0	c13	1	32-bit	Performance Monitors Event Type Select Register

IMPLEMENTATION DEFINED performance monitors

VMSAv8-32 reserves some additional System register encodings in the (coproc==0b1111) encoding space for optional additional IMPLEMENTATION DEFINED performance monitors. [Table G4-60](#) shows the allocation of these encodings:

Table G4-60 Performance Monitors System register encoding allocations

CRn	opc1	CRm	opc2	Name	Width	Type
c9	0-7	c12-c14	0-7	Performance Monitors Extension registers, see Table G4-59 on page G4-4738	32-bit	RW or RO ^a
		c15	0-7	IMPLEMENTATION DEFINED	32-bit	b

a. The table referenced in the *Name* entry shows the type of each of the OPTIONAL Performance Monitors Extension registers.

b. Access depends on the register or operation, and is IMPLEMENTATION DEFINED.

G4.17.14 Generic Timer registers, functional group

Table G4-61 shows the VMSAv8-32 System registers in the (coproc==0b1111) encoding space that are the Generic Time registers functional group.

Table G4-61 Generic Timer registers

Name	CRn	opc1	CRm	opc2	Width	Type ^a	Description
CNTRQ	c14	0	c0	0	32-bit	RW	Counter Frequency register
CNTHCTL	c14	4	c1	0	32-bit	RW	Timer EL2 Control register
CNTHP_CTL	c14	4	c2	1	32-bit	RW	EL2 Physical Timer Control register
CNTHP_CVAL	-	6	c14	-	64-bit	RW	EL2 Physical Timer CompareValue register
CNTHP_TVAL	c14	4	c2	0	32-bit	RW	EL2 Physical TimerValue register
CNTKCTL	c14	0	c1	0	32-bit	RW	Timer EL1 Control register
CNTP_CTL	c14	0	c2	1	32-bit	RW	EL1 Physical Timer Control register
CNTP_CVAL	-	2	c14	-	64-bit	RW	EL1 Physical Timer CompareValue register
CNTP_TVAL	c14	0	c2	0	32-bit	RW	EL1 Physical TimerValue register
CNTPCT	-	0	c14	-	64-bit	RW	Physical Count register
CNTV_CTL	c14	0	c3	1	32-bit	RW	Virtual Timer Control register
CNTV_CVAL	-	3	c14	-	64-bit	RW	Virtual Timer CompareValue register
CNTV_TVAL	c14	0	c3	0	32-bit	RW	Virtual TimerValue register
CNTVCT	-	1	c14	-	64-bit	RO	Virtual Count register
CNTVOFF ^b	-	4	c14	-	64-bit	RW	Virtual Offset register

- a. See the register descriptions for more information. Accessibility can depend on configuration settings as well as on the current Exception level.
- b. Implemented as RW as part of the Generic Timer on an implementation that includes EL2 and when EL2 is using AArch32. For more information see *Status of the CNTVOFF register* on page G5-4757.

G4.17.15 Generic Interrupt Controller System registers, functional groups

From version 3.0 of the GIC architecture specification, the specification defines three groups of System registers, identified by the prefix of the register name:

- ICC_** GIC physical CPU interface System registers.
- ICH_** GIC virtual interface control System registers.
- ICV_** GIC Virtual CPU interface System registers.

———— **Note** —————

These registers are in addition to the GIC memory-mapped register groups GICC_, GICD_, GICH_, GICR_, GICV_, and GITS_.

In VMSAv8-32, the GIC System registers are all in the (coproc==0b1111) encoding space with (CRn==c12). The ICV_* registers have the same {CRn, opc1, CRm, op2} encodings as the corresponding ICC_* registers. For these encodings, GIC register configuration fields determine which register is accessed.

For more information see the *ARM® Generic Interrupt Controller Architecture Specification, GIC architecture version 3.0 and version 4.0*.

Table G4-62 shows the functional groups of GIC System registers.

Table G4-62 Generic Interrupt Controller System registers

Name	CRn	opc1	CRm	opc2	Width	Type	Description
ICC_AP0R0 ^a ICV_AP0R0 ^a	c12	0	c8	4	32-bit	RW	Interrupt Controller Active Priorities Register (0,0) Interrupt Controller Virtual Active Priorities Register (0,0)

ICH_VTR	c12	4	c11	1	32-bit	RO	Interrupt Controller VGIC Type Register

a. As described in this section, these ICC_* and ICV_* registers use the same encodings.

G4.17.16 Legacy feature registers, functional group

Table G4-63 shows the VMSAv8-32 System registers in the (coproc==0b1111) encoding space that are in the Legacy features registers functional group.

Table G4-63 Legacy features System registers in the (coproc==0b1111) encoding space

Name	CRn	opc1	CRm	opc2	Width	Type ^a	Description
CP15DMB	c7	0	c10	5	32-bit	WO, PL0	<i>Memory barriers on page E2-2768^b</i>
CP15DSB	c7	0	c10	4	32-bit	WO, PL0	
CP15ISB	c7	0	c5	4	32-bit	WO, PL0	
FCSEIDR	c13	0	c0	0	32-bit	RW ^c	FCSE Process ID Register

- a. PL0 in a Type description indicates that the encoding is accessible by software executing at PL0. See the register description for more information.
- b. For performance reasons, ARM deprecates any use of these memory barrier operations.
- c. In ARMv8, the PE does not implement the FCSEIDR, and therefore the register is RAZ/WI. See the register description for more information.

Table G4-64 shows the VMSAv8-32 System registers in the (coproc==0b1110) encoding space that are in the Legacy features registers functional group.

Table G4-64 Legacy features registers in the (coproc==0b1110) encoding space

Name	CRn	opc1	CRm	opc2	Width	Type	Description
JIDR	c0	7	c0	0	32-bit	RO	Jazelle ID Register
JMCR	c2	7	c0	0	32-bit	RW	Jazelle Main Configuration Register
JOSCR	c1	7	c0	0	32-bit	RW	Jazelle OS Control Register

G4.17.17 IMPLEMENTATION DEFINED registers, functional group

VMSAv8-32 defines some encodings for registers with content that is entirely IMPLEMENTATION DEFINED.

Table G4-65 shows these registers in the (coproc==0b1111) encoding space.

Table G4-65 Architectural encodings for registers with IMPLEMENTATION DEFINED content

Name	CRn	opc1	CRm	opc2	Width	Type	Description
ACTLR	c1	0	c0	1	32-bit	RW	Auxiliary Control Register
ACTLR2	c1	0	c0	3	32-bit	RW	Auxiliary Control Register 2
ADFSR	c5	0	c1	0	32-bit	RW	Auxiliary Data Fault Status Register
AIDR	c0	1	c0	7	32-bit	RO	Auxiliary ID Register
AIFSR	c5	0	c1	1	32-bit	RW	Auxiliary Instruction Fault Status Register
AMAIRO	c10	0	c3	0	32-bit	RW	Auxiliary Memory Attribute Indirection Register 0
AMAIR1	c10	0	c3	1	32-bit	RW	Auxiliary Memory Attribute Indirection Register 1
HACR	c1	4	c1	7	32-bit	RW	Hyp Auxiliary Configuration Register
HACTLR	c1	4	c0	0	32-bit	RW	Hyp Auxiliary System Control Register

Table G4-65 Architectural encodings for registers with IMPLEMENTATION DEFINED content (continued)

Name	CRn	opc1	CRm	opc2	Width	Type	Description
HACTLR2	c1	4	c0	3	32-bit	RW	Hyp Auxiliary System Control Register 2
HADFSR	c5	4	c1	0	32-bit	RW	Hyp Auxiliary Data Fault Status Register
HAIFSR	c5	4	c1	1	32-bit	RW	Hyp Auxiliary Instruction Fault Status Register
HAMAIRO	c10	4	c3	0	32-bit	RW	Hyp Auxiliary Memory Attribute Indirection Register 0
HAMAIRI	c10	4	c3	1	32-bit	RW	Hyp Auxiliary Memory Attribute Indirection Register 1
REVIDR	c0	0	c0	6	32-bit	RO	Revision ID Register
TCMTR	c0	0	c0	2	32-bit	RO	TCM Type Register

See also *IMPLEMENTATION DEFINED performance monitors* on page G4-4739.

G4.17.18 Advanced SIMD and floating-point registers, functional group

[Table G4-66](#) shows the VMSAv8-32 System registers in the Advanced SIMD and floating-point registers functional group. These registers are accessed using VMRS and VMSR instructions, see the register descriptions for more information.

Table G4-66 Floating-point registers

Name	Width	Type	Description
FPEXC	32-bit	RW	Floating-Point Exception Control register
FPSCR	32-bit	RW	Floating-Point Status and Control Register
FPSID	32-bit	RW ^a	Floating-Point System ID register
MVFR0	32-bit	RO	Media and VFP Feature Register 0
MVFR1	32-bit	RO	Media and VFP Feature Register 1
MVFR2	32-bit	RO	Media and VFP Feature Register 2

a. When the [FPSID](#) is accessible, VMSR accesses to the [FPSID](#) are ignored.

G4.17.19 Debug registers, functional group

In AArch32 state, most Debug registers that are accessible through the System registers interface use {coproc==0b1110, opc1==0} encodings. [Table G4-67](#) shows these registers.

Table G4-67 System register {coproc == 0b1110, opc1 == 0} encodings of Debug registers

Name	CRn	opc2	CRm	Width	Type	Description

SDCR	c1	0	c3	1	32-bit	RW	Secure Debug Configuration Register
SDER	c1	0	c1	1	32-bit	RW	Secure Debug Enable Register

G4.18 Pseudocode description of VMSAv8-32 memory system operations

This section contains a list of pseudocode functions describing VMSAv8-32 memory operations. The following subsections describe the pseudocode functions:

- [Alignment fault.](#)
- [Address translation.](#)
- [Domain checking.](#)
- [TLB operations.](#)
- [Translation table walk.](#)
- [Reporting syndrome information on page G4-4749.](#)
- [Memory access decode when TEX remap is enabled on page G4-4749.](#)

See also the descriptions of pseudocode for general memory system operations in [Pseudocode description of general memory system instructions on page G3-4553.](#)

G4.18.1 Alignment fault

The `AArch32.AlignmentFault()` pseudocode function describes the generation of an Alignment fault Data Abort exception.

See also [Abort exceptions on page G3-4555.](#)

G4.18.2 Address translation

The `AArch32.TranslateAddress()` and `AArch32.FullTranslate()` pseudocode functions describe a VMSAv8-32 address translation.

The `AArch32.FullTranslate()` function calls either:

- The function described in [Address translation when the stage 1 address translation is disabled.](#)
- One of the functions described in [Translation table walk.](#)

See also [Stage 2 translation table walk on page G4-4749.](#)

Address translation when the stage 1 address translation is disabled

The `AArch32.TranslateAddressS10ff()` pseudocode function describes the address translation performed when the stage 1 address translation is disabled.

G4.18.3 Domain checking

The `AArch32.CheckDomain()` pseudocode function describes domain checking.

G4.18.4 TLB operations

The `TLBRecord` type represents the contents of a TLB entry:

G4.18.5 Translation table walk

Because of the complexity of a translation table walk, the following sections describe the different cases:

- [Translation table walk using the Short-descriptor translation table format for stage 1.](#)
- [Translation table walk using the Long-descriptor translation table format for stage 1 on page G4-4749.](#)
- [Stage 2 translation table walk on page G4-4749.](#)

Translation table walk using the Short-descriptor translation table format for stage 1

The `AArch32.TranslationTableWalkSD()` pseudocode function describes the translation table walk when the stage 1 translation tables use the Short-descriptor format. It calls the function described in [Stage 2 translation table walk on page G4-4749](#) if necessary.

The `ShortConvertAttrHints()` pseudocode function converts the Normal memory cacheability attribute, from the TTBR or the translation table TEX field, into the separate cacheability attribute and cache allocation hint defined in a Long-descriptor translation table descriptor.

Translation table walk using the Long-descriptor translation table format for stage 1

The `AArch32.TranslationTableWalkLD()` pseudocode function describes the translation table walk when the stage 1 translation tables use the Long-descriptor format. It calls the function described in *Stage 2 translation table walk* if necessary.

`AArch32.TranslationTableWalkLD()` calls the `ConvertAttrHints()` pseudocode function that is defined in *Translation table walk using the Short-descriptor translation table format for stage 1* on page G4-4748.

The `AArch32.S1AttrDecode()` pseudocode function uses the MAIR0 and MAIR1 registers to decode the Attr[2:0] value from a stage 1 translation table descriptor.

The `S2AttrDecode()` pseudocode function decodes the Attr[3:0] value from a stage 2 translation table descriptor.

Stage 2 translation table walk

In the Non-secure EL1&0 translation regime, a descriptor address returned by stage 1 lookup is in the IPA address map, and must be mapped to a PA by a stage 2 translation. When EL2 is using AArch32, function `AArch32.SecondStageWalk()` performs this translation, by calling the `AArch32.SecondStageTranslate()` function. When called from `AArch32.SecondStageWalk()`, the `AArch32.SecondStageTranslate()` function performs a second stage translation, from IPA to PA, of the supplied address, including checking that the access has read permission at the second stage. If the access does not have second stage read permission it generates a second stage Permission fault on the first stage translation table walk. The second stage translation might hit in a TLB, or might involve a translation table walk, which will use the algorithm described in this section. Stage 2 translations tables always use the Long-descriptor translation table format.

The `AArch32.CheckPermission()` pseudocode function checks the access permissions for the stage 1 translation.

The `AArch32.CheckS2Permission()` pseudocode function checks the access permissions for the stage 2 translation.

The `CombineS1S2Desc()` pseudocode function combines the stage 1 and stage 2 access descriptors:

G4.18.6 Reporting syndrome information

The `AArch32.ReportHypEntry()`, `AArch32.ReportDataAbort()`, and `AArch32.ReportPrefetchAbort()` pseudocode functions write syndrome value information to the appropriate registers for the current mode.

G4.18.7 Memory access decode when TEX remap is enabled

When using the Short-descriptor translation table format, the function `AArch32.RemappedTEXDecode()` decodes the texcb and S attributes derived from the translation tables when TEX remap is enabled. *Short-descriptor format memory region attributes, with TEX remap* on page G4-4619 shows the interpretation of the arguments.

Chapter G5

The Generic Timer in AArch32 state

This chapter describes the implementation of the ARM Generic Timer as an extension to an ARMv8 implementation. It includes an overview of the AArch32 System register interface to an ARM Generic Timer.

It contains the following sections:

- [About the Generic Timer in AArch32 state on page G5-4752.](#)
- [The AArch32 view of the Generic Timer on page G5-4756.](#)

[Chapter D6 The Generic Timer in AArch64 state](#) describes the AArch64 view of the Generic Timer, including an additional timer that can be implemented in AArch64 state, and [Chapter I1 System Level Implementation of the Generic Timer](#) describes the system level implementation of the Generic Timer.

G5.1 About the Generic Timer in AArch32 state

Figure G5-1 shows an example system-on-chip that uses the Generic Timer as a system timer. In this figure:

- This manual defines the architecture of the individual PEs in the multiprocessor blocks.
- The *ARM Generic Interrupt Controller Architecture Specification* defines a possible architecture for the interrupt controllers.
- Generic Timer functionality is distributed across multiple components.

Figure G5-1 Generic Timer example

The Generic Timer:

- Provides a system counter, that measures the passing of time in real-time.

———— **Note** ————

The Generic Timer can also provide other components at a system level, but Figure G5-1 does not show any such components.

- Supports *virtual counters* that measure the passing of virtual-time. That is, a virtual counter can measure the passing of time on a particular virtual machine.
- Timers, that can trigger events after a period of time has passed. The timers:
 - Can be used as count-up or as count-down timers.
 - Can operate in real-time or in virtual-time.

This chapter describes an instance of the Generic Timer component that Figure G5-1 shows as Timer_0 or Timer_1 within the Multiprocessor A or Multiprocessor B block. This component can be accessed from AArch64 state or AArch32 state, and this chapter describes access from AArch32 state. Chapter D6 *The Generic Timer in AArch64 state* describes access to this component from AArch64 state.

———— **Note** ————

The reset requirements of Generic Timer registers are more strict when they are accessed from AArch32 state than when they are accessed from AArch64 state.

A Generic Timer implementation must also include a memory-mapped system component, see [The full set of Generic Timer components](#).

G5.1.1 The full set of Generic Timer components

Within a system that might include multiple PEs, a full set of Generic Timer components is as follows:

The system counter

This provides a uniform view of system time, see [The system counter on page G5-4754](#). Because this must be implemented at the system level, it is accessed through [The system level memory-mapped implementation of the Generic Timer](#). However, during initialization, a status register in each implemented timer in the system must be programmed with the frequency of the system counter, so that software can read this frequency.

PE implementations of the Generic Timer

Each PE implementation of the Generic Timer provides the following components:

- A physical counter, that gives access to the count value of the system counter.
- A virtual counter, that gives access to virtual time. In AArch32 state, the `CNTVOFF` register defines the offset between physical time, as defined by the value of the system counter, and virtual time.
- A number of timers. In an implementation where all Exception levels are implemented and can use AArch32 state, the timers that are accessible from AArch64 state are:
 - A Secure PL1 physical timer.
 - A Non-secure EL1 physical timer.
 - An EL2 physical timer.
 - A virtual timer.

Note

The Secure PL1 physical timer uses the Secure banked instances of the `CNTP_CTL`, `CNTP_CVAL`, and `CNTP_TVAL` registers, and the Non-secure EL1 physical timer uses the Non-secure instances of the same registers.

[The AArch32 view of the Generic Timer on page G5-4756](#) describes these components.

The system level memory-mapped implementation of the Generic Timer

The memory-mapped registers that control the components of the system level implementation of the Generic Timer are grouped into *frames*. The Generic Timer architecture defines the offset of each register within its frame, but the base address of each frame is IMPLEMENTATION DEFINED, and defined by the system.

Each system level component has one or two register frames. The possible system level components are:

The memory-mapped counter module, required

This module controls the system counter. It has two frames:

- A control frame, `CNTControlBase`.
- A status frame, `CNTReadBase`.

The memory-mapped timer control module, required

The system level implementation of the Generic Timer can provide up to eight timers, and the memory-mapped timer control module identifies:

- Which timers are implemented.
- The features of each implemented timer.

This module has a single frame, `CNTCTLBase`.

Memory-mapped timers, optional

An implemented memory-mapped timer:

- Must provide a privileged view of the timer, in the `CNTBaseN` frame.

- Optionally, provides an unprivileged view of the timer in the CNTEL0BaseN frame.

N is the timer number, and the corresponding frame number, in the range 0-7.

[Chapter 11 System Level Implementation of the Generic Timer](#) describes these components.

G5.1.2 The system counter

The Generic Timer provides a system counter with the following specification:

Width	At least 56 bits wide. The value returned by any 64-bit read of the counter is zero-extended to 64 bits.
Frequency	Increments at a fixed frequency, typically in the range 1-50MHz. Can support one or more alternative operating modes in which it increments by larger amounts at a lower frequency, typically for power-saving.
Roll-over	Roll-over time of not less than 40 years.
Accuracy	ARM does not specify a required accuracy, but recommends that the counter does not gain or lose more than ten seconds in a 24-hour period. Use of lower-frequency modes must not affect the implemented accuracy.
Start-up	Starts operating from zero.

The system counter, once configured and running, must provide a uniform view of system time. More precisely, it must be impossible for the following sequence of events to show system time going backwards:

1. Device A reads the time from the system counter.
2. Device A communicates with another agent in the system, Device B.
3. After recognizing the communication from Device A, Device B reads the time from the system counter.

The system counter must be implemented in an always-on power domain.

To support lower-power operating modes, the counter can increment by larger amounts at a lower frequency. For example, a 10MHz system counter might either increment:

- By 1 at 10MHz.
- By 500 at 20kHz, when the system lowers the clock frequency, to reduce power consumption.

In this case, the counter must support transitions between high-frequency, high-precision operation, and lower-frequency, lower-precision operation, without any impact on the required accuracy of the counter.

The **CNTFRQ** register is intended to hold a copy of the current clock frequency to allow fast reference to this frequency by software running on the PE. For more information see [Initializing and reading the system counter frequency](#).

The mechanism by which the count from the system counter is distributed to system components is IMPLEMENTATION DEFINED, but each PE with a System register interface to the system counter must have a counter input that can capture each increment of the counter.

———— Note —————

So that the system counter can be clocked independently from the PE hardware, the count value might be distributed using a Gray code sequence. [Gray-count scheme for timer distribution scheme on page I1-5736](#) gives more information about this possibility.

Initializing and reading the system counter frequency

The **CNTFRQ** register must be programmed to the clock frequency of the system counter. Typically, this is done only during the system boot process, by using the System register interface to write the system counter frequency to the **CNTFRQ** register. Only software executing at the highest implemented Exception level can write to **CNTFRQ**.

Note

The [CNTFRQ](#) register is UNKNOWN at reset, and therefore the counter frequency must be set as part of the system boot process.

Software can read the [CNTFRQ](#) register, to determine the current system counter frequency, in the following states and modes:

- Hyp mode.
- Secure PL1 modes and Non-secure EL1 modes.
- When [CNTKCTL.PL0PCTEN](#) is set to 1, Secure and Non-secure EL0 modes.

Memory-mapped controls of the system counter

Some system counter controls are accessible only through the memory-mapped interface to the system counter. These controls are:

- Enabling and disabling the counter.
- Setting the counter value.
- Changing the operating mode, to change the update frequency and increment value.
- Enabling Halt-on-debug, that a debugger can then use to suspend counting.

For descriptions of these controls, see [Chapter 11 System Level Implementation of the Generic Timer](#).

G5.2 The AArch32 view of the Generic Timer

The following sections describe the components and features of a PE implementation of the Generic Timer, as seen from AArch32 state:

- [The physical counter](#).
- [The virtual counter](#).
- [Event streams on page G5-4757](#).
- [Timers on page G5-4758](#).

G5.2.1 The physical counter

The PE includes a physical counter that contains the count value of the system counter. The `CNTPCT` register holds the current physical counter value.

Accessing the physical counter

Software with sufficient privilege can read `CNTPCT` using a 64-bit System register read.

`CNTPCT`:

- Is always accessible from Secure PL1 modes and from Non-secure Hyp mode.
- Is accessible from Non-secure EL1 modes when the value of `CNTHCTL.PL1PCTEN` is 1. When the value of `CNTHCTL.PL1PCTEN` is 0, any attempt to access `CNTPCT` from Non-secure EL1 modes is trapped to Hyp mode.
- Is accessible from Secure User mode when the value of `CNTKCTL.PL0PCTEN` is 1. When the value of `CNTKCTL.PL0PCTEN` is 0, any attempt to access `CNTPCT` generates an UNDEFINED exception.
- Is accessible from Non-secure User mode when the value of `CNTHCTL.PL1PCTEN` is 1 and the value of `CNTKCTL.PL0PCTEN` is 1. Otherwise:
 - When the value of `CNTKCTL.PL0PCTEN` is 0, any attempt to access `CNTPCT` from Non-secure User mode generates an UNDEFINED exception.
 - When the value of `CNTKCTL.PL0PCTEN` is 1 and the value of `CNTHCTL.PL1PCTEN` is 0, any attempt to access `CNTPCT` from Non-secure User mode is trapped to Hyp mode.

Reads of `CNTPCT` can occur speculatively and out of order relative to other instructions executed on the same PE.

For example, if a read from memory is used to obtain a signal from another agent that indicates that `CNTPCT` must be read, an ISB is used to ensure that the read of `CNTPCT` occurs after the signal has been read from memory, as shown in the following code sequence:

```
loop                ; polling for some communication to indicate a requirement to read the timer
  LDR R1, [R2]
  CMP R1, #1
  BNE loop
  ISB                ; without this, the CNTPCT could be read before the memory location in [R2]
                    ; has had the value 1 written to it
  MRS R1, CNTPCT
```

G5.2.2 The virtual counter

An implementation of the Generic Timer always includes a virtual counter, that indicates virtual time.

The virtual counter contains the value of the physical counter minus a 64-bit virtual offset. When executing in a Non-secure EL1 or EL0 mode, the virtual offset value relates to the current virtual machine.

The `CNTVOFF` register contains the virtual offset. `CNTVOFF` is only accessible:

- From Hyp mode.
- From Monitor mode only when `SCR.NS` is set to 1.

For more information see [Status of the CNTVOFF register on page G5-4757](#).

The `CNTVCT` register holds the current virtual counter value.

Accessing the virtual counter

Software with sufficient privilege can read `CNTVCT` using a 64-bit System register read.

`CNTVCT` is always accessible from Secure PL1 modes and from Non-secure EL1 and EL2 modes.

In addition, when `CNTKCTL.PL0VCTEN` is set to 1, `CNTVCT` is accessible from EL0.

When `CNTKCTL.PL0VCTEN` is set to 0, any attempt to access `CNTVCT` from EL0 is UNDEFINED.

Reads of `CNTVCT` can occur speculatively and out of order relative to other instructions executed on the same PE.

For example, if a read from memory is used to obtain a signal from another agent that indicates that `CNTVCT` must be read, an ISB is used to ensure that the read of `CNTVCT` occurs after the signal has been read from memory, as shown in the following code sequence:

```
loop           ; polling for some communication to indicate a requirement to read the timer
  LDR R1, [R2]
  CMP R1, #1
  BNE loop
  ISB          ; without this, the CNTVCT could be read before the memory location in [R2]
               ; has had the value 1 written to it
  MRS R1, CNTVCT
```

Status of the CNTVOFF register

All implementations of the Generic Timer include the virtual counter. Therefore, conceptually, all implementations include the `CNTVOFF` register that defines the *virtual offset* between the physical count and the virtual count. `CNTVOFF` is only accessible at EL2 or above. If EL2 is not implemented, the virtual counter uses a fixed virtual offset of zero.

G5.2.3 Event streams

Any implementation of the Generic Timer can use the system counter to generate one or more *event streams*, to generate periodic wake-up events as part of the mechanism described in [Wait for Event mechanism and Send event on page D1-1879](#).

————— Note —————

An event stream might be used:

- To impose a time-out on a Wait For Event polling loop.
- To safeguard against any programming error that means an expected event is not generated.

An event stream is configured by:

- Selecting which bit, from the bottom 16 bits of a counter, triggers the event. This determines the frequency of the events in the stream.
- Selecting whether the event is generated on each 0 to 1 transition, or each 1 to 0 transition, of the selected counter bit.

The `CNTKCTL`.{EVNTEN, EVNTDIR, EVNTI} fields define an event stream that is generated from the virtual counter.

In all implementations the `CNTHCTL`.{EVNTEN, EVNTDIR, EVNTI} fields define an event stream that is generated from the physical counter.

The operation of an event stream is as follows:

- The pseudocode variables PreviousCNTVCT and PreviousCNTPCT are initialized as:

```
// Variables used for generation of the timer event stream.
```

```
bits(64) PreviousCNTVCT = bits(64) UNKNOWN;
bits(64) PreviousCNTPCT = bits(64) UNKNOWN;
```

- The pseudocode functions TestEventCNTV() and TestEventCNTP() are called on each cycle of the PE clock.
- The TestEventCNTx() pseudocode template defines the functions TestEventCNTV() and TestEventCNTP():

```
// TestEventCNTx()
// =====

// Template for the TestEventCNTV() and TestEventCNTP() functions
// Describes operation when all Exception Levels are using AArch32:
// CNTxCT      is CNTVCT      or CNTPCT      64-bit count value
// CNTx_CTL    is CNTV_CTL    or CNTP_CTL    Control register
// PreviousCNTxCT is PreviousCNTVCT or PreviousCNTPCT

TestEventCNTx()
    if CNTx_CTL.EVNTEN == '1' then
        n = UInt(CNTx_CTL.EVNTI);
        SampleBit = CNTxCT<n>;
        PreviousBit = PreviousCNTxCT<n>;

        if CNTx_CTL.EVNTDIR == '0' then
            if PreviousBit == '0' && SampleBit == '1' then EventRegisterSet();
        else
            if PreviousBit == '1' && SampleBit == '0' then EventRegisterSet();

        PreviousCNTxCT = CNTxCT;

    return;
```

G5.2.4 Timers

In an implementation that includes EL3, in any implementation of the Generic Timer, the following timers are accessible from AArch32 state, provided the appropriate Exception level can use AArch32:

- A Non-secure EL1 physical timer. A Non-secure EL1 control determines whether this register is accessible from Non-secure EL0.
- A Secure PL1 physical timer. This timer:
 - Is accessible from Secure EL1 using AArch32 when EL3 is using AArch64.
 - Is accessible from Secure EL3 when EL3 is using AArch32.
A Secure PL1 control determines whether this register is accessible from Secure EL0.
- A Non-secure EL2 physical timer.
- A virtual timer.

The output of each implemented timer:

- Provides an output signal to the system.
- If the PE interfaces to a *Generic Interrupt Controller* (GIC), signals a *Private Peripheral Interrupt* (PPI) to that GIC. In a multiprocessor implementation, each PE must use the same interrupt number for each timer.

Each timer:

- Is based around a 64-bit CompareValue that provides a 64-bit unsigned upcounter.
- Provides an alternative view of the CompareValue, called the TimerValue, that appears to operate as a 32-bit downcounter.
- Has, in addition, a 32-bit Control register.

In all implementations, the AArch32 System registers for the EL1 (or PL1) physical timer are Banked, to provide the Secure and Non-secure implementations of the timer. [Table G5-1](#) shows the Timer registers.

Table G5-1 Timer registers summary for the Generic Timer

Timer register	Secure PL1 or Non-secure EL1 physical timer	EL2 physical timer	Virtual timer
CompareValue register	CNTP_CVAL ^a	CNTHP_CVAL	CNTV_CVAL
TimerValue register	CNTP_TVAL ^a	CNTHP_TVAL	CNTV_TVAL
Control register	CNTP_CTL ^a	CNTHP_CTL	CNTV_CTL

a. In AArch32 state, these registers are Banked to provide the Non-secure EL1 physical timer and the Secure PL1 physical timer.

The following sections describe:

- [Accessing the timer registers](#)
- [Operation of the CompareValue views of the timers on page G5-4760](#)
- [Operation of the TimerValue views of the timers on page G5-4760.](#)

Accessing the timer registers

For each timer, all timer registers have the same access permissions, as follows:

Secure PL1 and Non-secure EL1 physical timer

The Secure PL1 physical timer is accessible from Secure PL1 modes.

Non-secure software executing at EL2 controls access to the Non-secure EL1 physical timer from Non-secure EL1 modes. The Non-secure EL1 physical timer is accessible from Monitor mode when the value of [SCR.NS](#) is 1.

When access from PL1 or EL1 modes is permitted, [CNTKCTL.PLOPTEN](#) determines whether the registers are accessible from EL0. If an access is not permitted because [CNTKCTL.PLOPTEN](#) is set to 0, an attempted access from EL0 is UNDEFINED.

In all implementations:

- Except for accesses from Monitor mode, accesses are to the registers for the current Security state.
- For accesses from Monitor mode, the value of [SCR.NS](#) determines whether accesses are to the Secure or the Non-secure registers.

————— Note —————

Monitor mode is present only when EL3 is using AArch32.

- The Non-secure registers are accessible from Hyp mode.
- [CNTHCTL.PL1PCEN](#) determines whether the Non-secure registers are accessible from Non-secure EL1 modes. If this bit is set to 1, to enable access from Non-secure EL1 modes, [CNTKCTL.PLOPTEN](#) determines whether the registers are accessible from Non-secure EL0.

If an access is not permitted because [CNTHCTL.PL1PCEN](#) is set to 0, an attempted access from a Non-secure EL1 or EL0 mode generates a Hyp Trap exception. However, if [CNTKCTL.PLOPTEN](#) is set to 0, this control takes priority, and an attempted access from EL0 is UNDEFINED.

EL2 physical timer Accessible from Hyp mode, and from Secure Monitor mode when [SCR_EL3.NS](#) is set to 1.

Virtual timer Accessible from Secure PL1 modes and Non-secure EL1 modes, and from Hyp mode.
CNTKCTL.PLOVTEN determines whether the registers are accessible from EL0 modes. If an access is not permitted because **CNTKCTL.PLOVTEN** is set to 0, an attempted access from EL0 is UNDEFINED.

Operation of the CompareValue views of the timers

The CompareValue view of a timer operates as a 64-bit upcounter. The timer condition is met when the appropriate counter reaches the value programmed into its CompareValue register. When the timer condition is met an interrupt is generated if the interrupt is not masked in the corresponding timer control register, **CNTP_CTL**, **CNTHP_CTL**, or **CNTV_CTL**. For **CNTP_CTL**, the interrupt is the same as the interrupt asserted by the Non-secure instance of the AArch64 register **CNTP_CTL_ELO**.

The operation of this view of a timer is:

$$\text{TimerConditionMet} = (((\text{Counter}[63:0] - \text{Offset}[63:0])[63:0] - \text{CompareValue}[63:0]) \geq 0)$$

Where:

TimerConditionMet Is TRUE if the timer condition for this counter is met, and FALSE otherwise.

Counter The physical counter value, that can be read from the **CNTPCT** register.

———— **Note** —————

The virtual counter value, that can be read from the **CNTVCT** register, is the value:

$$\frac{(\text{Counter} - \text{Offset})}{}$$

Offset For a physical timer it is zero, and for the virtual timer it is the virtual offset, held in the **CNTVOFF** register.

CompareValue The value of the appropriate CompareValue register, **CNTP_CVAL**, **CNTHP_CVAL**, or **CNTV_CVAL**.

In this view of a timer, Counter, Offset, and CompareValue are all 64-bit unsigned values.

———— **Note** —————

This means that a timer with a CompareValue of, or close to, 0xFFFF_FFFF_FFFF_FFFF might never meet its timer condition. However, there is no practical requirement to use values close to the counter wrap value.

Operation of the TimerValue views of the timers

The TimerValue view of a timer appears to operate as a signed 32-bit downcounter. A TimerValue register is programmed with a count value. This value decrements on each increment of the appropriate counter, and the timer condition is met when the value reaches zero. When the timer condition is met, an interrupt is generated if the interrupt is not masked in the corresponding timer control register, **CNTP_CTL**, **CNTHP_CTL**, or **CNTV_CTL**.

This view of a timer depends on the following behavior of accesses to TimerValue registers:

Reads $\text{TimerValue} = (\text{CompareValue} - (\text{Counter} - \text{Offset})) [31:0]$

Writes $\text{CompareValue} = ((\text{Counter} - \text{Offset}) [63:0] + \text{SignExtend}(\text{TimerValue})) [63:0]$

Where the arguments other than TimerValue have the definitions used in *Operation of the CompareValue views of the timers*, and in addition:

TimerValue The value of a TimerValue register, **CNTP_TVAL**, **CNTHP_TVAL**, or **CNTV_TVAL**.

In this view of a timer, values are signed, in standard two's complement form.

A read of a TimerValue register after the timer condition has been met indicates the time since the timer condition was met.

Note

- *Operation of the CompareValue views of the timers on page G5-4760* gives a strict definition of TimerConditionMet. However, provided that the TimerValue is not expected to wrap as a 32-bit signed value when decremented from 0x80000000, the TimerValue view can be used as giving an effect equivalent to:
TimerConditionMet = (TimerValue ≤ 0)
 - Programming TimerValue to a negative number with magnitude greater than (Counter–Offset) can lead to an arithmetic overflow that causes the CompareValue to be an extremely large positive value. This potentially delays meeting the timer condition for an extremely long period of time.
-

Chapter G6

AArch32 System Register Descriptions

This chapter describes each of the AArch32 System registers.

It contains the following sections:

- *About the AArch32 System registers* on page G6-4764.
- *General system control registers* on page G6-4774.
- *Debug registers* on page G6-5239.
- *Performance Monitors registers* on page G6-5331.
- *Generic Timer registers* on page G6-5383.

G6.1 About the AArch32 System registers

For general information about the AArch32 System registers, see:

- [About the System registers for VMSAv8-32 on page G4-4689.](#)
- [VMSAv8-32 organization of registers in the \(coproc == 0b1110\) encoding space on page G4-4704.](#)
- [VMSAv8-32 organization of registers in the \(coproc == 0b1111\) encoding space on page G4-4707.](#)
- [Functional grouping of VMSAv8-32 System registers on page G4-4726.](#)

The remainder of this chapter describes the AArch32 System registers, in the following sections:

- [General system control registers on page G6-4774.](#)
- [Debug registers on page G6-5239.](#)
- [Performance Monitors registers on page G6-5331.](#)
- [Generic Timer registers on page G6-5383.](#)

G6.1.1 General behavior of System registers

Except where indicated, System registers are 32-bits wide. As stated in [About the System registers for VMSAv8-32 on page G4-4689](#), there are some 64-bit registers, and these include cases where software can access either a 32-bit view or a 64-bit view of a register. The register summaries, and the individual register descriptions, identify the 64-bit registers and how they can be accessed.

The following sections give information about the general behavior of these registers. Unless otherwise indicated, information applies to all AArch32 System registers:

- [Register names.](#)
- [Read-only bits in read/write registers.](#)
- [UNPREDICTABLE, CONSTRAINED UNPREDICTABLE, and UNDEFINED behavior for AArch32 System register accesses.](#)
- [Read-only and write-only register encodings on page G6-4766.](#)
- [Reset behavior of AArch32 System registers on page G6-4767.](#)

See also [About AArch32 System register accesses on page G4-4689](#) and [Fixed values in register diagrams on page G4-4701](#).

Register names

The ARM architecture guarantees not to define any register name prefixed with *IMP_* as part of the standard ARM architecture.

———— Note —————

ARM strongly recommends that any register names created in the IMPLEMENTATION DEFINED register spaces be prefixed with *IMP_*, where appropriate.

Read-only bits in read/write registers

Some read/write registers include bits that are read-only. These bits ignore writes.

An example of this is the [SCTLR.NMFI bit, SCTLR\[27\]](#).

UNPREDICTABLE, CONSTRAINED UNPREDICTABLE, and UNDEFINED behavior for AArch32 System register accesses

This section defines UNPREDICTABLE and UNDEFINED behaviors for accesses to System registers, including those cases where the ARMv8 behavior is CONSTRAINED UNPREDICTABLE.

In AArch32 state the following operations are UNDEFINED:

- All LDC and STC accesses, except for the LDC access to [DBGDTRTXint](#) and the STC access to [DBGDTRRXint](#) specified in [Table G4-43 on page G4-4706](#).
- All MCRR and MRRC operations to the (coproc==0b111x) encoding space, except for those explicitly defined as accessing 64-bit System registers specified in [Table G4-42 on page G4-4705](#) and [Table G4-44 on page G4-4711](#).

Unless otherwise indicated in the individual register descriptions:

- Reserved fields in registers are RES0.
- Assigning a reserved value to a field has a CONSTRAINED UNPREDICTABLE effect, see [Reserved values in System and memory-mapped registers and translation table entries on page K1-6117](#).

The following subsections give more information about UNPREDICTABLE, CONSTRAINED UNPREDICTABLE, and UNDEFINED behavior for accesses to the (coproc==0b111x) encoding space:

- [Accesses to unallocated encodings in the \(coproc==0b111x\) encoding space](#).
- [Additional rules for MCR and MRC accesses to System registers](#).
- [Effects of EL3 and EL2 on System register accesses](#).

Accesses to unallocated encodings in the (coproc==0b111x) encoding space

In ARMv8-A, accesses to unallocated register encodings in the (coproc==0b111x) encoding space are UNDEFINED, see [Unallocated System register access instructions on page K1-6100](#).

Additional rules for MCR and MRC accesses to System registers

The following operations are CONSTRAINED UNPREDICTABLE for all encodings in the (coproc==0b111x) encoding space:

- All MCR operations from the PC.
- All MRC operations to APSR_nzcv, except for the (coproc==0b1110) MRC operation to APSR_nzcv from [DBGDSCRint](#).

The CONSTRAINED UNPREDICTABLE behavior of these operations is that they are UNDEFINED, see [Unallocated System register access instructions on page K1-6100](#).

For registers and operations that are accessible from a particular Privilege level, any attempt to access those registers from a lower Privilege level is UNDEFINED.

Some individual registers can be made inaccessible by setting configuration bits, possibly including IMPLEMENTATION DEFINED configuration bits, to disable access to the register. The effects of the architecturally-defined configuration bits are defined individually in this manual. Unless explicitly stated otherwise in this manual, setting a configuration bit to disable access to a register results in the register becoming UNDEFINED for MRC and MCR accesses.

See also [Read-only and write-only register encodings on page G6-4766](#).

Effects of EL3 and EL2 on System register accesses

EL2 and EL3 introduce classes of System registers, described in [Classification of System registers on page G4-4692](#). Some of these classes of register are either:

- Accessible only from certain modes or states.
- Accessible from certain modes or states only when configuration settings permit the access.

Accesses to these registers that are not permitted are UNDEFINED, meaning execution of the register access instruction generates an Undefined Instruction exception.

Note

This section applies only to registers that are accessible from some modes and states. That is, it applies only to register access instructions using an encoding that, under some circumstances, would perform a valid register access.

The following register classes restrict access in this way:

Restricted access System registers

This register class is defined in any implementation that includes EL3.

Restricted access registers other than the [NSACR](#) are accessible only from Secure EL3 modes. All other accesses to these registers are UNDEFINED.

The [NSACR](#) is a special case of a Restricted access register and:

- The [NSACR](#) is:
 - Read/write accessible from Secure PL1 modes.
 - Is Read-only accessible from Non-secure PL2 and PL1 modes.
- All other accesses to the [NSACR](#) are UNDEFINED.

For more information, including behavior when EL3 is using AArch64 or is not implemented, see [Restricted access System registers on page G4-4694](#).

Configurable access System registers

This register class is defined in any implementation that includes EL3.

Most Configurable access registers are accessible from Non-secure state only if control bits in the [NSACR](#) permit Non-secure access to the register. Otherwise, a Non-secure access to the register is UNDEFINED.

For other Configurable access registers, control bits in the [NSACR](#) control the behavior of bits or fields in the register when it is accessed from Non-secure state. That is, Non-secure accesses to the register are permitted, but the [NSACR](#) controls how they behave. The only architecturally-defined register of this type is the [CPACR](#).

For more information, see [Configurable access System registers on page G4-4694](#).

EL2-mode System registers

This register class is defined only in an implementation that includes EL2.

EL2-mode registers are accessible only from:

- The Non-secure EL2 mode, Hyp mode.
- Secure Monitor mode when [SCR.NS](#) is set to 1.

All other accesses to these registers are UNDEFINED.

For more information, see [Hyp mode read/write registers in the \(coproc == 0b1111\) encoding space on page G4-4695](#) and [Hyp mode encodings for shared \(coproc == 0b1111\) System registers on page G4-4696](#).

EL2-mode write-only operations

This register class is defined only in an implementation that includes EL2.

EL2-mode write-only operations are accessible only from:

- The Non-secure EL2 mode, Hyp mode.
- Secure Monitor mode, regardless of the value of [SCR.NS](#).

Write accesses to these operations are:

- CONSTRAINED UNPREDICTABLE in Secure EL3 modes other than Monitor mode.
- UNDEFINED in Non-secure modes other than Hyp mode.

For more information, see [Hyp mode \(coproc == 0b1111\) write-only System instructions on page G4-4697](#).

In addition, in any implementation that includes EL3, when EL3 is using AArch32, if write access to a register is disabled by the [CP15SSDISABLE](#) signal then any MCR access to that register is UNDEFINED.

Read-only and write-only register encodings

Some System registers are *read-only* (RO) or *write-only* (WO). For example:

- Most identification registers are read-only.

- Most encodings that perform an operation, such as a cache maintenance instruction, are write-only.

If a particular Privilege level defines a register to be:

- RO, then any attempt to write to that register, at that Privilege level, is UNDEFINED. This means that any access to that register with $L == 0$ is UNDEFINED.
- WO, then any attempt to read from that register, at that Privilege level, is UNDEFINED. This means that any access to that register with $L == 1$ is UNDEFINED.

For IMPLEMENTATION DEFINED encoding spaces, the treatment of the encodings is IMPLEMENTATION DEFINED.

Note

This section applies only to registers that this manual defines as RO or WO. It does not apply to registers for which other access permissions are explicitly defined.

Reset behavior of AArch32 System registers

Reset values apply only to RW registers and fields, however:

- Some RO registers or fields, including feature ID registers and some status registers or register fields, always return a known value.
- Some RW and RO registers or register fields return status information about the PE. Unless the register description indicates that the value is UNKNOWN on reset, a read of the register immediately after a reset returns valid information.
- Some RW and RO registers and fields are aliases of other registers or fields. In these cases, the reset behavior of the aliased register or field determines the value returned by a read of the register immediately after a reset.
- WO registers that only have an effect on writes do not have meaningful reset values. However, an access to a WO register might affect underlying state, and that state might have a defined reset value.
- IMPLEMENTATION DEFINED registers have IMPLEMENTATION DEFINED reset behavior.

After a reset, only a limited subset of the PE state is guaranteed to be set to defined values. Also, for debug and trace System registers, reset requirements must take account of different levels of reset. For more information about the reset behavior of System registers when the PE resets into an Exception level that is using AArch32, see:

- [PE state on reset into AArch32 state on page G1-4400](#).
- The appropriate Trace architecture specification, for the Trace System registers.

When the PE resets into an Exception level that is using AArch64, PE state that relates to execution in AArch32 state, including the System register values, is UNKNOWN. The only exception to this is state that applies to execution in both AArch64 state and AArch32 state and that has a defined reset value on the reset into AArch64 state. An example of such PE state is the [EDPRSR.SR](#) bit.

For a PE reset into an Exception level that is using AArch32, the architecture defines which AArch32 System registers have a defined reset value, and when that defined reset value applies. The register descriptions include this information, and [PE state on reset into AArch32 state on page G1-4400](#) summarizes these architectural requirements. Otherwise, RW registers reset to an architecturally unknown value.

Note

In an implementation that includes EL3, unless this manual explicitly states otherwise, only the Secure instance of a Banked register is reset to the defined value. This means that software must program the Non-secure instance of the register with the required values. Typically, this programming is part of the PE boot sequence.

Pseudocode description of resetting System registers

The [AArch32.ResetControlRegisters\(\)](#) pseudocode function resets all System registers, and register fields, that have defined reset values, as described in this section and [PE state on reset into AArch32 state on page G1-4400](#).

Note

For debug and trace System registers, this function resets registers as defined for the appropriate level of reset.

Synchronization of changes to AArch32 System registers

In this section, *this PE* means the PE on which accesses are being synchronized.

Note

See [Definitions of direct and indirect reads and writes and their side-effects on page G6-4772](#) for definitions of the terms *direct write*, *direct read*, *indirect write*, and *indirect read*.

A *direct write* to a System register might become visible at any point after the change to the register, but without a [Context synchronization event](#) there is no guarantee that the change becomes visible.

Any direct write to a System register is guaranteed not to affect any instruction that appears, in program order, before the instruction that performed the direct write, and any direct write to a System register must be synchronized before any instruction that appears after the direct write, in program order, can rely on the effect of that write. The only exceptions to this are:

- All direct writes to the same register, using the same encoding, are guaranteed to occur in program order.
- All direct writes to a register are guaranteed to occur in program order relative to all direct reads of the same register using the same encoding.
- Any System register access that an ARM *Architecture Specification* or equivalent specification defines as not requiring synchronization.
- If an instruction that appears in program order before the direct write performs a memory access, such as a memory-mapped register access, that causes an indirect read or write to a register, that memory access is subject to the memory order model. In this case, if permitted by the memory order model, the instruction that appears in program order before the direct write can be affected by the direct write. For information about the memory order model, see [Definition of the ARMv8 memory model on page E2-2762](#).

These rules mean that an instruction that writes to one of the address translation instructions described in [Address translation instructions on page G4-4682](#) must be explicitly synchronized to guarantee that the result of the address translation instruction is visible in the [PAR](#).

Note

In this case, the direct write to the encoding of the address translation instruction causes an *indirect write* to the [PAR](#). Without a [Context synchronization event](#) after the direct write, there is no guarantee that the indirect write to the [PAR](#) is visible.

Conceptually, the explicit synchronization occurs as the first step of any [Context synchronization event](#). This means that if the operation uses the state that had been changed but not synchronized before the operation occurred, the operation is guaranteed to use the state as if it had been synchronized.

Note

- This explicit synchronization is applied as the first step of the execution of any instruction that causes the synchronization operation. This means it does not synchronize any effect of changes to the System registers that might affect the fetch and decode of the instructions that cause the operation, such as breakpoints or changes to translation tables.
 - For a synchronous exception, the control state in use at the time the exception is generated determines the exception syndrome information, and this syndrome information is not changed by this synchronization at the start of taking the exception.
-

Except for the register reads listed in *Registers with some architectural guarantee of ordering or observability* on page G6-4771, if no *Context synchronization event* is performed, direct reads of System registers can occur in any order.

Table G6-1 shows the synchronization requirement between two reads or writes that access the same System register. In the column headings, *First* and *Second* refer to:

- Program order, for any read or write caused by the execution of an instruction by this PE, other than a read or write caused by a memory access made by that instruction.
- The order of arrival of asynchronous reads or writes made by this PE relative to the execution of instructions by this PE.

In addition:

- For indirect reads or writes caused by an external agent, such as a debugger, the mechanism that determines the order of the reads or writes is defined by that external agent. The external agent can provide mechanisms that ensure that any read or write it makes arrives at the PE. These indirect reads and writes are asynchronous to software execution on the PE.
- For indirect reads or writes caused by memory-mapped reads or writes made by this PE, the ordering of the memory accesses is subject to the memory order model, including the effect of the memory type of the accessed memory address. This applies, for example, if this PE reads or writes one of its registers in a memory-mapped register interface.

The mechanism for ensuring completion of these memory accesses, including ensuring the arrival of the asynchronous read or write at the PE, is defined by the system.

———— **Note** —————

Such accesses are likely to be given a Device memory attribute, but requiring this is outside the scope of the architecture.

- For indirect reads or writes caused by autonomous asynchronous events that are counted, for example events caused by the passage of time, the events are ordered so that:
 - Counts progress monotonically.
 - The events arrive at the PE in finite time and without undue delay.

Table G6-1 Synchronization requirements for updates to System registers

First read or write	Second read or write	<i>Context synchronization event</i> required
Direct read	Direct read	No
	Direct write	No
	Indirect read	No ^a
	Indirect write	No ^a , but see text in this section for exceptions
Direct write	Direct read	No
	Direct write	No
	Indirect read	Yes ^a
	Indirect write	No, but see text in this section for exceptions

Table G6-1 Synchronization requirements for updates to System registers (continued)

First read or write	Second read or write	<i>Context synchronization event</i> required
Indirect read	Direct read	No
	Direct write	No
	Indirect read	No
	Indirect write	No
Indirect write	Direct read	Yes, but see text in this section for exceptions
	Direct write	No, but see text in this section for exceptions
	Indirect read	Yes, but see text in this section for exceptions
	Indirect write	No, but see text in this section for exceptions

- a. Although no synchronization is required between a Direct write and a Direct read, or between a Direct read and an Indirect write, this does not imply that a Direct read causes synchronization of a previous Direct write. This means that the sequence Direct write followed by Direct read followed by Indirect read, with no intervening context synchronization, does not guarantee that the Indirect read observes the result of the Direct write.

If the indirect write is to a register that [Registers with some architectural guarantee of ordering or observability on page G6-4771](#) shows as having some guarantee of the visibility of an indirect write, synchronization might not be required.

If a direct read or a direct write to a register is followed by an indirect write to that register that is caused by an external agent, or by an autonomous asynchronous event, or as a result of a memory-mapped write, then synchronization is required to guarantee the ordering of the indirect write relative to the direct read or direct write.

If an indirect write caused by a direct write is followed by an indirect write caused by an external agent, or by an autonomous asynchronous event, or as a result of a memory-mapped write, then synchronization is required to guarantee the ordering of the two indirect writes.

If a direct read causes an indirect write, synchronization is required to guarantee that the indirect write is visible to subsequent direct or indirect reads or writes. This synchronization must be performed after the direct read, before any subsequent direct or indirect read or write.

If a direct write causes an indirect write, synchronization is required to guarantee that the indirect write is visible to subsequent direct or indirect reads or writes. This synchronization must be performed after the direct write, before any subsequent direct or indirect read or write.

———— **Note** —————

Where a register has more than one encoding, a direct write to the register using a particular encoding is not an indirect write to the same register with a different encoding.

Where an indirect write is caused by the action of an external agent, such as a debugger, or by a memory-mapped read or write by the PE, then an indirect write by that agent to a register using a particular access mechanism, followed by an indirect read by that agent to the same register using the same access mechanism and address does not need synchronization.

For information about the additional synchronization requirements for memory-mapped registers, see [Synchronization requirements for AArch64 System registers on page D7-2191](#).

To guarantee the visibility of changes to some registers, additional operations might be required before the *Context synchronization event*. For such a register, the definition of the register identifies these additional requirements.

In this manual, unless the context indicates otherwise:

- *Accessing* a System register refers to a direct read or write of the register.
- *Using* a System register refers to an indirect read or write of the register.

Registers with some architectural guarantee of ordering or observability

For the registers for which [Table G6-2](#) shows that the ordering of direct reads is guaranteed, multiple direct reads of a single register, using the same encoding, occur in program order without any explicit ordering.

For the registers for which [Table G6-2](#) shows that some observability of indirect writes is guaranteed, an indirect write to the register caused by an external agent, an autonomous asynchronous event, or as a result of a memory-mapped write, is both:

- Observable to direct reads of the register, in finite time, without explicit synchronization.
- Observable to subsequent indirect reads of the register without explicit synchronization.

These two sets of registers are similar, as [Table G6-2](#) shows:

Table G6-2 Registers with a guarantee of ordering or observability, VMSAv8-32

Register	Ordering of direct reads	Observability of indirect writes	Notes
ISR	Guaranteed	Guaranteed	Interrupt Status Register
DBGCLAIMCLR	Guaranteed	Guaranteed	Debug CLAIM registers
DBGCLAIMSET	-	Guaranteed	
DBGDTRRXint	Guaranteed	Guaranteed	Debug Communication Channel registers
DBGDTRTXint	-	Guaranteed	
The DCC flags in DBGDSCRint	Guaranteed	Guaranteed	
CNTPCT	Guaranteed	Guaranteed	Generic Timer registers
CNTP_TVAL	Guaranteed	Guaranteed	
CNTVCT	Guaranteed	Guaranteed	
CNTV_TVAL	Guaranteed	Guaranteed	
CNTHP_TVAL	Guaranteed	Guaranteed	
PMCCNTR	Guaranteed	Guaranteed	
PMEVCNTR<n>	Guaranteed	Guaranteed	
PMXVCNTR	Guaranteed	Guaranteed	
PMOVSSET	Guaranteed	Guaranteed	
PMOVSRR	Guaranteed	Guaranteed	
EDSCR .PipeAdv and the DCC flags in EDSCR	-	Guaranteed	Fields of the External Debug Status and Control Register

In addition to the requirements shown in [Table G6-2](#):

- Indirect writes to the following registers as a result of memory-mapped writes, including accesses by external agents, are required to be observable to the indirect read made in determining the response to a subsequent memory-mapped access without explicit synchronization:

- [OSLAR_EL1](#). [OSLAR_EL1](#) is indirectly read to determine whether the subsequent access is permitted.

———— **Note** —————

[OSLAR_EL1](#) maps to the AArch32 System register [DBGOSLAR](#).

- [EDLAR](#), if implemented. [EDLAR](#) is indirectly read to determine whether a subsequent write or side-effect of an access is ignored.

———— **Note** —————

This requirement is stricter than the general requirement for the observability of indirect writes.

- When the PE is in Debug state, there are synchronization requirements for the Debug Communication Channel and Instruction Transfer registers. See [DCC and ITR access in Debug state](#) on page H4-5513.

The possibility that direct reads can occur *early*, in the absence of context synchronization, described in [Ordering of reads of System registers](#) on page G4-4689, still applies to the registers listed in [Table G6-2](#) on page G6-4771.

Definitions of direct and indirect reads and writes and their side-effects

Direct and indirect reads and writes are defined as follows:

Direct read Is a read of a register, using an MRC, MRRC, or STC instruction, that the architecture permits for the current PE state.

If a direct read of a register has a side-effect of changing the value of a register, the effect of a direct read on that register is defined to be an *indirect write*, and has the synchronization requirements of an indirect write. This means the indirect write is guaranteed to have occurred, and to be visible to subsequent direct or indirect reads and writes only if synchronization is performed after the direct read.

———— **Note** —————

The indirect write described here can affect either the register written to by the direct write, or some other register. The synchronization requirement is the same in both cases.

Direct write Is a write to a register, using an MCR, MCRR, or LDC instruction, that the architecture permits for the current PE state.

In the following cases, the side-effect of the direct write is defined to be an indirect write of the affected register, and has the synchronization requirements of an indirect write:

- If the direct write has a side-effect of changing the value of a register other than the register accessed by the direct write.
- If the direct write has a side-effect of changing the value of the register accessed by the direct write, so that the value in that register might not be the value that the direct write wrote to the register.

In both cases, this means that the indirect write is not guaranteed to be visible to subsequent direct or indirect reads and writes unless synchronization is performed after the direct write.

———— **Note** —————

- As an example of a direct write to a register having an effect that is an indirect write of that register, writing 1 to a [PMCNTENCLR.Px](#) bit is also an indirect write, because if the Px bit had the value 1 before the direct write, the side-effect of the write changes the value of that bit to 0.
- The indirect write described here can affect either the register written to by the direct write, or some other register. The synchronization requirement is the same in both cases.
For example, writing 1 to a [PMCNTENCLR.Px](#) bit that is set to 1 also changes the corresponding [PMCNTENSET.Px](#) bit from 1 to 0. This means that the direct write to the [PMCNTENCLR](#) defines indirect writes to both itself and to the [PMCNTENSET](#).

Indirect read Is a use of the register by an instruction to establish the operating conditions for the instruction. Examples of operating conditions that might be determined by an indirect read are the translation table base address, or whether memory accesses are forced to be Non-cacheable.

Indirect reads include situations where the value of one register determines what value is returned by a second register. This means that any read of the second register is an indirect read of the register that determines what value is returned.

Indirect reads also include:

- Reads of the System registers by external agents, such as debuggers, as described in [Debug registers on page G6-5239](#).
- Memory-mapped reads of the System registers made by the PE on which the System registers are implemented.

Where an indirect read of a register has a side-effect of changing the value of a register, that change is defined to be an indirect write, and has the synchronization requirements of an indirect write.

Indirect write Is an update to the value of a register as a consequence of either:

- An exception, operation, or execution of an instruction that is not a direct write to that register.
- The asynchronous operation of an external agent.

This can include:

- The passage of time, as seen in counters or timers, including performance counters.
- The assertion of an interrupt.
- A write from an external agent, such as a debugger.

However, for some registers, the architecture gives some guarantee of visibility without any explicit synchronization, see [Registers with some architectural guarantee of ordering or observability on page G6-4771](#).

———— **Note** —————

Taking an exception is a context-synchronizing operation. Therefore, any indirect write performed as part of an exception entry does not require additional synchronization. This includes the indirect writes to the registers that report the exception, as described in [Exception reporting in a VMSAv8-32 implementation on page G4-4663](#).

G6.2 General system control registers

This section lists the System registers in AArch32 state that are not part of one of the other listed groups.

G6.2.1 ACTLR, Auxiliary Control Register

The ACTLR characteristics are:

Purpose

Provides IMPLEMENTATION DEFINED configuration and control options for execution at EL1 and EL0.

Configurations

AArch32 System register ACTLR is architecturally mapped to AArch64 System register [ACTLR_EL1](#)[31:0].

Some bits might define global configuration settings, and be common to the Secure and Non-secure instances of the register.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

ACTLR is a 32-bit register.

Field descriptions

The ACTLR bit assignments are:

IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

Accessing the ACTLR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c1, c0, 1	000	001	0001	1111	0000

Accessibility

The register is accessible in software as follows:

Configuration	Control			Accessibility				Instance
	E2H	TGE	NS	EL0	EL1	EL2	EL3	
EL3 is using AArch32.	x	x	0	-	n/a	n/a	RW	ACTLR_s
EL3 is using AArch32.	x	0	1	-	RW	RW	RW	ACTLR_ns
EL3 is using AArch32.	x	1	1	-	n/a	RW	RW	ACTLR_ns
EL3 is not implemented.	x	x	0	-	RW	n/a	n/a	ACTLR
EL3 is not implemented.	x	0	1	-	RW	RW	n/a	ACTLR
EL3 is not implemented.	x	1	1	-	n/a	RW	n/a	ACTLR
EL3 is using AArch64.	x	x	0	-	RW	n/a	n/a	ACTLR
EL3 is using AArch64.	x	0	1	-	RW	RW	n/a	ACTLR
EL3 is using AArch64.	x	1	1	-	n/a	RW	n/a	ACTLR

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If HCR_EL2.TACR==1, Non-secure accesses to this register from EL1 are trapped to EL2 using AArch64.
 - If HSTR_EL2.T1==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If HCR_EL2.TACR==1, Non-secure accesses to this register from EL1 are trapped to EL2 using AArch64.
 - If HSTR_EL2.T1==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HCR.TAC==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
 - If HSTR.T1==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

G6.2.2 ACTLR2, Auxiliary Control Register 2

The ACTLR2 characteristics are:

Purpose

Provides additional space to the ACTLR register to hold IMPLEMENTATION DEFINED trap functionality for execution at EL1 and EL0.

Configurations

AArch32 System register ACTLR2 is architecturally mapped to AArch64 System register [ACTLR_EL1](#)[63:32].

In ARMv8.0 and ARMv8.1, it is IMPLEMENTATION DEFINED whether this register is implemented, or whether it causes UNDEFINED exceptions when accessed. The implementation of this register can be detected by examining [ID_MMFR4.AC2](#).

From ARMv8.2 this register must be implemented.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

ACTLR2 is a 32-bit register.

Field descriptions

The ACTLR2 bit assignments are:

IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

Accessing the ACTLR2

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c1, c0, 3	000	011	0001	1111	0000

Accessibility

The register is accessible in software as follows:

Configuration	Control			Accessibility				Instance
	E2H	TGE	NS	EL0	EL1	EL2	EL3	
EL3 is not implemented.	x	x	0	-	RW	n/a	n/a	ACTLR2
EL3 is not implemented.	x	0	1	-	RW	RW	n/a	ACTLR2
EL3 is not implemented.	x	1	1	-	n/a	RW	n/a	ACTLR2
EL3 is using AArch64.	x	x	0	-	RW	n/a	n/a	ACTLR2
EL3 is using AArch64.	x	0	1	-	RW	RW	n/a	ACTLR2
EL3 is using AArch64.	x	1	1	-	n/a	RW	n/a	ACTLR2
EL3 is using AArch32.	x	x	0	-	n/a	n/a	RW	ACTLR2_s
EL3 is using AArch32.	x	0	1	-	RW	RW	RW	ACTLR2_ns
EL3 is using AArch32.	x	1	1	-	n/a	RW	RW	ACTLR2_ns

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If HCR_EL2.TACR==1, Non-secure accesses to this register from EL1 are trapped to EL2 using AArch64.
 - If HSTR_EL2.T1==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If HCR_EL2.TACR==1, Non-secure accesses to this register from EL1 are trapped to EL2 using AArch64.
 - If HSTR_EL2.T1==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HCR.TAC==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
 - If HSTR.T1==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

G6.2.3 ADFSR, Auxiliary Data Fault Status Register

The ADFSR characteristics are:

Purpose

Provides additional IMPLEMENTATION DEFINED fault status information for Data Abort exceptions taken to EL1 modes, and EL3 modes when EL3 is implemented and is using AArch32.

Configurations

AArch32 System register ADFSR is architecturally mapped to AArch64 System register [AFSR0_EL1](#).

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

ADFSR is a 32-bit register.

Field descriptions

The ADFSR bit assignments are:

IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

Accessing the ADFSR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c5, c1, 0	000	000	0101	1111	0001

Accessibility

The register is accessible in software as follows:

Configuration	Control			Accessibility				Instance
	E2H	TGE	NS	EL0	EL1	EL2	EL3	
EL3 is not implemented.	x	x	0	-	RW	n/a	n/a	ADFSR
EL3 is not implemented.	x	0	1	-	RW	RW	n/a	ADFSR
EL3 is not implemented.	x	1	1	-	n/a	RW	n/a	ADFSR
EL3 is using AArch64.	x	x	0	-	RW	n/a	n/a	ADFSR
EL3 is using AArch64.	x	0	1	-	RW	RW	n/a	ADFSR
EL3 is using AArch64.	x	1	1	-	n/a	RW	n/a	ADFSR
EL3 is using AArch32.	x	x	0	-	n/a	n/a	RW	ADFSR_s
EL3 is using AArch32.	x	0	1	-	RW	RW	RW	ADFSR_ns
EL3 is using AArch32.	x	1	1	-	n/a	RW	RW	ADFSR_ns

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If HCR_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
 - If HCR_EL2.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If HSTR_EL2.T5==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If HCR_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
 - If HCR_EL2.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If HSTR_EL2.T5==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HCR.TVM==1, Non-secure write accesses to this register from EL1 are trapped to Hyp mode.
 - If HCR.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
 - If HSTR.T5==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

G6.2.4 AIDR, Auxiliary ID Register

The AIDR characteristics are:

Purpose

Provides IMPLEMENTATION DEFINED identification information.

The value of this register must be used in conjunction with the value of [MIDR](#).

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register AIDR is architecturally mapped to AArch64 System register [AIDR_EL1](#).

Attributes

AIDR is a 32-bit register.

Field descriptions

The AIDR bit assignments are:

IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

Accessing the AIDR

This register can be read using MRC with the following syntax:

MRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 1, <Rt>, c0, c0, 7	001	111	0000	1111	0000

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	RO	n/a	RO
x	0	1	-	RO	RO	RO
x	1	1	-	n/a	RO	RO

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 0)$:
 - If $HCR_EL2.TID1 == 1$, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If $HSTR_EL2.T0 == 1$, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 1) \ \&\& \ (HCR_EL2.TGE == 0)$:
 - If $HCR_EL2.TID1 == 1$, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If $HSTR_EL2.T0 == 1$, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $HCR.TID1 == 1$, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
 - If $HSTR.T0 == 1$, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.

G6.2.5 AIFSR, Auxiliary Instruction Fault Status Register

The AIFSR characteristics are:

Purpose

Provides additional IMPLEMENTATION DEFINED fault status information for Prefetch Abort exceptions taken to EL1 modes, and EL3 modes when EL3 is implemented and is using AArch32.

Configurations

AArch32 System register AIFSR is architecturally mapped to AArch64 System register [AFSR1_EL1](#).

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

AIFSR is a 32-bit register.

Field descriptions

The AIFSR bit assignments are:

IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

Accessing the AIFSR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c5, c1, 1	000	001	0101	1111	0001

Accessibility

The register is accessible in software as follows:

Configuration	Control			Accessibility				Instance
	E2H	TGE	NS	EL0	EL1	EL2	EL3	
EL3 is using AArch32.	x	x	0	-	n/a	n/a	RW	AIFSR_s
EL3 is not implemented.	x	x	0	-	RW	n/a	n/a	AIFSR
EL3 is not implemented.	x	0	1	-	RW	RW	n/a	AIFSR

Configuration	Control			Accessibility				Instance
	E2H	TGE	NS	EL0	EL1	EL2	EL3	
EL3 is not implemented.	x	1	1	-	n/a	RW	n/a	AIFSR
EL3 is using AArch64.	x	x	0	-	RW	n/a	n/a	AIFSR
EL3 is using AArch64.	x	0	1	-	RW	RW	n/a	AIFSR
EL3 is using AArch64.	x	1	1	-	n/a	RW	n/a	AIFSR
EL3 is using AArch32.	x	0	1	-	RW	RW	RW	AIFSR_ns
EL3 is using AArch32.	x	1	1	-	n/a	RW	RW	AIFSR_ns

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If HCR_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
 - If HCR_EL2.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If HSTR_EL2.T5==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If HCR_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
 - If HCR_EL2.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If HSTR_EL2.T5==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HCR.TVM==1, Non-secure write accesses to this register from EL1 are trapped to Hyp mode.
 - If HCR.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
 - If HSTR.T5==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

G6.2.6 AMAIR0, Auxiliary Memory Attribute Indirection Register 0

The AMAIR0 characteristics are:

Purpose

When using the Long-descriptor format translation tables for stage 1 translations, provides IMPLEMENTATION DEFINED memory attributes for the memory regions specified by [MAIR0](#).

Configurations

AArch32 System register AMAIR0 is architecturally mapped to AArch64 System register [AMAIR_EL1](#)[31:0].

When EL3 is using AArch32, write access to AMAIR0(S) is disabled when the CP15SDISABLE signal is asserted HIGH.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

AMAIR0 is a 32-bit register.

Field descriptions

The AMAIR0 bit assignments are:

This register is RES0 in the following cases:

- When an implementation does not provide any IMPLEMENTATION DEFINED memory attributes.
- When the Long-descriptor translation table format is not used.

If EL3 is implemented and is using AArch32:

- AMAIR0(S) gives the value for memory accesses from Secure state.
- AMAIR0(NS) gives the value for memory accesses from Non-secure states other than Hyp mode.

Any IMPLEMENTATION DEFINED memory attributes are additional qualifiers for the memory locations and must not change the architected behavior specified by [MAIR0](#) and [MAIR1](#).

In a typical implementation, AMAIR0 and [AMAIR1](#) split into eight one-byte fields, corresponding to the MAIRn.Attr<n> fields, but the architecture does not require them to do so.

IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

Accessing the AMAIR0

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c10, c3, 0	000	000	1010	1111	0011

Accessibility

The register is accessible in software as follows:

Configuration	Control			Accessibility				Instance
	E2H	TGE	NS	EL0	EL1	EL2	EL3	
EL3 is not implemented.	x	x	0	-	RW	n/a	n/a	AMAIRO
EL3 is not implemented.	x	0	1	-	RW	RW	n/a	AMAIRO
EL3 is not implemented.	x	1	1	-	n/a	RW	n/a	AMAIRO
EL3 is using AArch64.	x	x	0	-	RW	n/a	n/a	AMAIRO
EL3 is using AArch64.	x	0	1	-	RW	RW	n/a	AMAIRO
EL3 is using AArch64.	x	1	1	-	n/a	RW	n/a	AMAIRO
EL3 is using AArch32.	x	0	1	-	RW	RW	RW	AMAIRO_ns
EL3 is using AArch32.	x	1	1	-	n/a	RW	RW	AMAIRO_ns
EL3 is using AArch32.	x	x	0	-	n/a	n/a	RW	AMAIRO_s

When EL3 is using AArch32, write access to AMAIRO_s is UNDEFINED when the CP15SSDISABLE signal is asserted HIGH.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If HCR_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
 - If HCR_EL2.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If HSTR_EL2.T10==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If HCR_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
 - If HCR_EL2.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If HSTR_EL2.T10==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HCR.TVM==1, Non-secure write accesses to this register from EL1 are trapped to Hyp mode.
 - If HCR.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
 - If HSTR.T10==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

G6.2.7 AMAIR1, Auxiliary Memory Attribute Indirection Register 1

The AMAIR1 characteristics are:

Purpose

When using the Long-descriptor format translation tables for stage 1 translations, provides IMPLEMENTATION DEFINED memory attributes for the memory regions specified by MAIR1.

Configurations

AArch32 System register AMAIR1 is architecturally mapped to AArch64 System register AMAIR_EL1[63:32].

When EL3 is using AArch32, write access to AMAIR1(S) is disabled when the CP15SDISABLE signal is asserted HIGH.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

AMAIR1 is a 32-bit register.

Field descriptions

The AMAIR1 bit assignments are:

This register is RES0 in the following cases:

- When an implementation does not provide any IMPLEMENTATION DEFINED memory attributes.
- When the Long-descriptor translation table format is not used.

If EL3 is implemented and is using AArch32:

- AMAIR1(S) gives the value for memory accesses from Secure state.
- AMAIR1(NS) gives the value for memory accesses from Non-secure states other than Hyp mode.

Any IMPLEMENTATION DEFINED memory attributes are additional qualifiers for the memory locations and must not change the architected behavior specified by MAIR0 and MAIR1.

In a typical implementation, AMAIR0 and AMAIR1 split into eight one-byte fields, corresponding to the MAIRn.Attr<n> fields, but the architecture does not require them to do so.

IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

Accessing the AMAIR1

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c10, c3, 1	000	001	1010	1111	0011

Accessibility

The register is accessible in software as follows:

Configuration	Control			Accessibility				Instance
	E2H	TGE	NS	EL0	EL1	EL2	EL3	
EL3 is not implemented.	x	x	0	-	RW	n/a	n/a	AMAIR1
EL3 is not implemented.	x	0	1	-	RW	RW	n/a	AMAIR1
EL3 is not implemented.	x	1	1	-	n/a	RW	n/a	AMAIR1
EL3 is using AArch64.	x	x	0	-	RW	n/a	n/a	AMAIR1
EL3 is using AArch64.	x	0	1	-	RW	RW	n/a	AMAIR1
EL3 is using AArch64.	x	1	1	-	n/a	RW	n/a	AMAIR1
EL3 is using AArch32.	x	0	1	-	RW	RW	RW	AMAIR1_ns
EL3 is using AArch32.	x	1	1	-	n/a	RW	RW	AMAIR1_ns
EL3 is using AArch32.	x	x	0	-	n/a	n/a	RW	AMAIR1_s

When EL3 is using AArch32, write access to AMAIR1_s is UNDEFINED when the CP15SSDISABLE signal is asserted HIGH.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If HCR_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
 - If HCR_EL2.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If HSTR_EL2.T10==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If HCR_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
 - If HCR_EL2.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If HSTR_EL2.T10==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HCR.TVM==1, Non-secure write accesses to this register from EL1 are trapped to Hyp mode.
 - If HCR.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
 - If HSTR.T10==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

G6.2.8 APSR, Application Program Status Register

The APSR characteristics are:

Purpose

Hold program status and control information.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

Attributes

APSR is a 32-bit register.

Field descriptions

The APSR bit assignments are:

N, bit [31]

Negative condition flag. Set to bit[31] of the result of the last flag-setting instruction. If the result is regarded as a two's complement signed integer, then N is set to 1 if the result was negative, and N is set to 0 if the result was positive or zero.

Z, bit [30]

Zero condition flag. Set to 1 if the result of the last flag-setting instruction was zero, and to 0 otherwise. A result of zero often indicates an equal result from a comparison.

C, bit [29]

Carry condition flag. Set to 1 if the last flag-setting instruction resulted in a carry condition, for example an unsigned overflow on an addition.

V, bit [28]

Overflow condition flag. Set to 1 if the last flag-setting instruction resulted in an overflow condition, for example a signed overflow on an addition.

Q, bit [27]

Cumulative saturation bit. Set to 1 to indicate that overflow or saturation occurred in some instructions.

Bits [26:20]

Reserved, RES0.

GE, bits [19:16]

Greater than or Equal flags, for parallel addition and subtraction.

Bits [15:5]

Reserved, RES0.

Bit [4]

Reserved, RES1.

Bits [3:0]

Reserved, RES0.

G6.2.9 ATS12NSOPR, Address Translate Stages 1 and 2 Non-secure Only PL1 Read

The ATS12NSOPR characteristics are:

Purpose

Performs stage 1 and 2 address translations as defined for PL1 and the Non-secure state, with permissions as if reading from the given virtual address.

Configurations

There are no configuration notes.

Attributes

ATS12NSOPR is a 32-bit System instruction.

Field descriptions

The ATS12NSOPR input value bit assignments are:

Bits [31:0]

Input address for translation. The resulting address can be read from the [PAR](#).

This instruction takes a VA as input. The resulting address is the PA that is the output address of the stage 2 translation.

Executing the ATS12NSOPR instruction

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c7, c8, 4	000	100	0111	1111	1000

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	WO
x	0	1	-	-	WO	WO
x	1	1	-	n/a	WO	WO

If EL3 is implemented and is using AArch64, execution of ATS12NSOPR in Secure EL1 using AArch32 is trapped as an exception to EL3.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \&\& (HCR_EL2.E2H == 0)$:
 - If $HSTR_EL2.T7 == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \&\& (HCR_EL2.E2H == 1) \&\& (HCR_EL2.TGE == 0)$:
 - If $HSTR_EL2.T7 == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $HSTR.T7 == 1$, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

G6.2.10 ATS12NSOPW, Address Translate Stages 1 and 2 Non-secure Only PL1 Write

The ATS12NSOPW characteristics are:

Purpose

Performs stage 1 and 2 address translations as defined for PL1 and the Non-secure state, with permissions as if writing to the given virtual address.

Configurations

There are no configuration notes.

Attributes

ATS12NSOPW is a 32-bit System instruction.

Field descriptions

The ATS12NSOPW input value bit assignments are:

Bits [31:0]

Input address for translation. The resulting address can be read from the [PAR](#).

This instruction takes a VA as input. The resulting address is the PA that is the output address of the stage 2 translation.

Executing the ATS12NSOPW instruction

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c7, c8, 5	000	101	0111	1111	1000

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	WO
x	0	1	-	-	WO	WO
x	1	1	-	n/a	WO	WO

If EL3 is implemented and is using AArch64, execution of ATS12NSOPW in Secure EL1 using AArch32 is trapped as an exception to EL3.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \&\& (HCR_EL2.E2H == 0)$:
 - If $HSTR_EL2.T7 == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \&\& (HCR_EL2.E2H == 1) \&\& (HCR_EL2.TGE == 0)$:
 - If $HSTR_EL2.T7 == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $HSTR.T7 == 1$, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

G6.2.11 ATS12NSOUR, Address Translate Stages 1 and 2 Non-secure Only Unprivileged Read

The ATS12NSOUR characteristics are:

Purpose

Performs stage 1 and 2 address translations as defined for PL0 and the Non-secure state, with permissions as if reading from the given virtual address.

Configurations

There are no configuration notes.

Attributes

ATS12NSOUR is a 32-bit System instruction.

Field descriptions

The ATS12NSOUR input value bit assignments are:

Bits [31:0]

Input address for translation. The resulting address can be read from the [PAR](#).

This instruction takes a VA as input. The resulting address is the PA that is the output address of the stage 2 translation.

Executing the ATS12NSOUR instruction

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c7, c8, 6	000	110	0111	1111	1000

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	WO
x	0	1	-	-	WO	WO
x	1	1	-	n/a	WO	WO

If EL3 is implemented and is using AArch64, execution of ATS12NSOUR in Secure EL1 using AArch32 is trapped as an exception to EL3.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \&\& (HCR_EL2.E2H == 0)$:
 - If $HSTR_EL2.T7 == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \&\& (HCR_EL2.E2H == 1) \&\& (HCR_EL2.TGE == 0)$:
 - If $HSTR_EL2.T7 == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $HSTR.T7 == 1$, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

G6.2.12 ATS12NSOUW, Address Translate Stages 1 and 2 Non-secure Only Unprivileged Write

The ATS12NSOUW characteristics are:

Purpose

Performs stage 1 and 2 address translations as defined for PL0 and the Non-secure state, with permissions as if writing to the given virtual address.

Configurations

There are no configuration notes.

Attributes

ATS12NSOUW is a 32-bit System instruction.

Field descriptions

The ATS12NSOUW input value bit assignments are:

Bits [31:0]

Input address for translation. The resulting address can be read from the [PAR](#).

This instruction takes a VA as input. The resulting address is the PA that is the output address of the stage 2 translation.

Executing the ATS12NSOUW instruction

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c7, c8, 7	000	111	0111	1111	1000

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	WO
x	0	1	-	-	WO	WO
x	1	1	-	n/a	WO	WO

If EL3 is implemented and is using AArch64, execution of ATS12NSOUW in Secure EL1 using AArch32 is trapped as an exception to EL3.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 0)$:
 - If $HSTR_EL2.T7 == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 1) \ \&\& \ (HCR_EL2.TGE == 0)$:
 - If $HSTR_EL2.T7 == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $HSTR.T7 == 1$, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

G6.2.13 ATS1CPR, Address Translate Stage 1 Current state PL1 Read

The ATS1CPR characteristics are:

Purpose

Performs stage 1 address translation as defined for PL1 and the current Security state, with permissions as if reading from the given virtual address.

Configurations

There are no configuration notes.

Attributes

ATS1CPR is a 32-bit System instruction.

Field descriptions

The ATS1CPR input value bit assignments are:

Bits [31:0]

Input address for translation. The resulting address can be read from the [PAR](#).

This instruction takes a VA as input. In an implementation that includes EL2, when executed in Non-secure state, the resulting address is the IPA that is the output address of the stage 1 translation. Otherwise, the resulting address is a PA.

Executing the ATS1CPR instruction

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c7, c8, 0	000	000	0111	1111	1000

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	WO	n/a	WO
x	0	1	-	WO	WO	WO
x	1	1	-	n/a	WO	WO

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \&\& (HCR_EL2.E2H == 0)$:
 - If $HSTR_EL2.T7 == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \&\& (HCR_EL2.E2H == 1) \&\& (HCR_EL2.TGE == 0)$:
 - If $HSTR_EL2.T7 == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $HSTR.T7 == 1$, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

G6.2.14 ATS1CPRP, Address Translate Stage 1 Current state PL1 Read PAN

The ATS1CPRP characteristics are:

Purpose

When [ARMv8.2-ATS1E1](#) is implemented, performs a stage 1 address translation at PL1 and in the current Security state, where the value of PSTATE.PAN determines if a read from a location will generate a permission fault for a privileged access.

Configurations

This instruction is introduced in ARMv8.2.

Attributes

ATS1CPRP is a 32-bit System instruction.

Field descriptions

The ATS1CPRP input value bit assignments are:

Bits [31:0]

Input address for translation. The resulting address can be read from the [PAR](#).

This instruction takes a VA as input. In an implementation that includes EL2, when executed in Non-secure state, the resulting address is the IPA that is the output address of the stage 1 translation. Otherwise, the resulting address is a PA.

Executing the ATS1CPRP instruction

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c7, c9, 0	000	000	0111	1111	1001

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	WO	n/a	WO
x	0	1	-	WO	WO	WO
x	1	1	-	n/a	WO	WO

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 0)$:
 - If $HSTR_EL2.T7 == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 1) \ \&\& \ (HCR_EL2.TGE == 0)$:
 - If $HSTR_EL2.T7 == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $HSTR.T7 == 1$, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

G6.2.15 ATS1CPW, Address Translate Stage 1 Current state PL1 Write

The ATS1CPW characteristics are:

Purpose

Performs stage 1 address translation as defined for PL1 and the current Security state, with permissions as if writing to the given virtual address.

Configurations

There are no configuration notes.

Attributes

ATS1CPW is a 32-bit System instruction.

Field descriptions

The ATS1CPW input value bit assignments are:

Bits [31:0]

Input address for translation. The resulting address can be read from the [PAR](#).

This instruction takes a VA as input. In an implementation that includes EL2, when executed in Non-secure state, the resulting address is the IPA that is the output address of the stage 1 translation. Otherwise, the resulting address is a PA.

Executing the ATS1CPW instruction

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c7, c8, 1	000	001	0111	1111	1000

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	WO	n/a	WO
x	0	1	-	WO	WO	WO
x	1	1	-	n/a	WO	WO

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \&\& (HCR_EL2.E2H == 0)$:
 - If $HSTR_EL2.T7 == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \&\& (HCR_EL2.E2H == 1) \&\& (HCR_EL2.TGE == 0)$:
 - If $HSTR_EL2.T7 == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $HSTR.T7 == 1$, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

G6.2.16 ATS1CPWP, Address Translate Stage 1 Current state PL1 Write PAN

The ATS1CPWP characteristics are:

Purpose

When [ARMv8.2-ATS1E1](#) is implemented, performs a stage 1 address translation at PL1 and in the current Security state, where the value of PSTATE.PAN determines if a write to the location will generate a permission fault for a privileged access.

Configurations

This instruction is introduced in ARMv8.2.

Attributes

ATS1CPWP is a 32-bit System instruction.

Field descriptions

The ATS1CPWP input value bit assignments are:

Bits [31:0]

Input address for translation. The resulting address can be read from the [PAR](#).

This instruction takes a VA as input. In an implementation that includes EL2, when executed in Non-secure state, the resulting address is the IPA that is the output address of the stage 1 translation. Otherwise, the resulting address is a PA.

Executing the ATS1CPWP instruction

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c7, c9, 1	000	001	0111	1111	1001

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	WO	n/a	WO
x	0	1	-	WO	WO	WO
x	1	1	-	n/a	WO	WO

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \&\& (HCR_EL2.E2H == 0)$:
 - If $HSTR_EL2.T7 == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \&\& (HCR_EL2.E2H == 1) \&\& (HCR_EL2.TGE == 0)$:
 - If $HSTR_EL2.T7 == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $HSTR.T7 == 1$, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

G6.2.17 ATS1CUR, Address Translate Stage 1 Current state Unprivileged Read

The ATS1CUR characteristics are:

Purpose

Performs stage 1 address translation as defined for PL0 and the current Security state, with permissions as if reading from the given virtual address.

Configurations

There are no configuration notes.

Attributes

ATS1CUR is a 32-bit System instruction.

Field descriptions

The ATS1CUR input value bit assignments are:

Bits [31:0]

Input address for translation. The resulting address can be read from the [PAR](#).

This instruction takes a VA as input. In an implementation that includes EL2, when executed in Non-secure state, the resulting address is the IPA that is the output address of the stage 1 translation. Otherwise, the resulting address is a PA.

Executing the ATS1CUR instruction

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c7, c8, 2	000	010	0111	1111	1000

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	WO	n/a	WO
x	0	1	-	WO	WO	WO
x	1	1	-	n/a	WO	WO

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 0)$:
 - If $HSTR_EL2.T7 == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 1) \ \&\& \ (HCR_EL2.TGE == 0)$:
 - If $HSTR_EL2.T7 == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $HSTR.T7 == 1$, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

G6.2.18 ATS1CUW, Address Translate Stage 1 Current state Unprivileged Write

The ATS1CUW characteristics are:

Purpose

Performs stage 1 address translation as defined for PL0 and the current Security state, with permissions as if writing to the given virtual address.

Configurations

There are no configuration notes.

Attributes

ATS1CUW is a 32-bit System instruction.

Field descriptions

The ATS1CUW input value bit assignments are:

Bits [31:0]

Input address for translation. The resulting address can be read from the [PAR](#).

This instruction takes a VA as input. In an implementation that includes EL2, when executed in Non-secure state, the resulting address is the IPA that is the output address of the stage 1 translation. Otherwise, the resulting address is a PA.

Executing the ATS1CUW instruction

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c7, c8, 3	000	011	0111	1111	1000

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	WO	n/a	WO
x	0	1	-	WO	WO	WO
x	1	1	-	n/a	WO	WO

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 0)$:
 - If $HSTR_EL2.T7 == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 1) \ \&\& \ (HCR_EL2.TGE == 0)$:
 - If $HSTR_EL2.T7 == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $HSTR.T7 == 1$, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

G6.2.19 ATS1HR, Address Translate Stage 1 Hyp mode Read

The ATS1HR characteristics are:

Purpose

Performs stage 1 address translation as defined for PL2 and the Non-secure state, with permissions as if reading from the given virtual address.

Configurations

There are no configuration notes.

Attributes

ATS1HR is a 32-bit System instruction.

Field descriptions

The ATS1HR input value bit assignments are:

Bits [31:0]

Input address for translation. The resulting address can be read from the [PAR](#).

This instruction takes a VA as input. The resulting address is the PA that is the output address of the translation.

Executing the ATS1HR instruction

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 4, <Rt>, c7, c8, 0	100	000	0111	1111	1000

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	WO
x	0	1	-	-	WO	WO
x	1	1	-	n/a	WO	WO

If this instruction is executed in a Secure privileged mode other than Monitor mode, then the behavior is CONSTRAINED UNPREDICTABLE, and one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The instruction executes as if it had been executed in Monitor mode.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 0)$:
 - If $HSTR_EL2.T7 == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 1) \ \&\& \ (HCR_EL2.TGE == 0)$:
 - If $HSTR_EL2.T7 == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $HSTR.T7 == 1$, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

G6.2.20 ATS1HW, Address Translate Stage 1 Hyp mode Write

The ATS1HW characteristics are:

Purpose

Performs stage 1 address translation as defined for PL2 and the Non-secure state, with permissions as if writing to the given virtual address.

Configurations

There are no configuration notes.

Attributes

ATS1HW is a 32-bit System instruction.

Field descriptions

The ATS1HW input value bit assignments are:

Bits [31:0]

Input address for translation. The resulting address can be read from the [PAR](#).

This instruction takes a VA as input. The resulting address is the PA that is the output address of the translation.

Executing the ATS1HW instruction

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 4, <Rt>, c7, c8, 1	100	001	0111	1111	1000

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	WO
x	0	1	-	-	WO	WO
x	1	1	-	n/a	WO	WO

If this instruction is executed in a Secure privileged mode other than Monitor mode, then the behavior is CONSTRAINED UNPREDICTABLE, and one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The instruction executes as if it had been executed in Monitor mode.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 0)$:
 - If $HSTR_EL2.T7 == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 1) \ \&\& \ (HCR_EL2.TGE == 0)$:
 - If $HSTR_EL2.T7 == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $HSTR.T7 == 1$, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

G6.2.21 BPIALL, Branch Predictor Invalidate All

The BPIALL characteristics are:

Purpose

Invalidate all entries from branch predictors.

Configurations

In an implementation where the branch predictors are architecturally invisible, this instruction can execute as a NOP.

Attributes

BPIALL is a 32-bit System instruction.

Field descriptions

BPIALL ignores the value in the register specified by the instruction. Software does not have to write a value to the register before issuing this instruction.

Executing the BPIALL instruction

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c7, c5, 6	000	110	0111	1111	0101

The PE ignores the value of <Rt>. Software does not have to write a value to this register before issuing this instruction.

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	WO	n/a	WO
x	0	1	-	WO	WO	WO
x	1	1	-	n/a	WO	WO

When [HCR.FB](#) is 1, at Non-secure EL1 this instruction executes as a [BPIALLIS](#).

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 0)$:
 - If $HSTR_EL2.T7 == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 1) \ \&\& \ (HCR_EL2.TGE == 0)$:
 - If $HSTR_EL2.T7 == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $HSTR.T7 == 1$, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

G6.2.22 BPIALLIS, Branch Predictor Invalidate All, Inner Shareable

The BPIALLIS characteristics are:

Purpose

Invalidate all entries from branch predictors Inner Shareable.

Configurations

In an implementation where the branch predictors are architecturally invisible, this instruction can execute as a NOP.

Attributes

BPIALLIS is a 32-bit System instruction.

Field descriptions

BPIALLIS ignores the value in the register specified by the instruction. Software does not have to write a value to the register before issuing this instruction.

Executing the BPIALLIS instruction

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c7, c1, 6	000	110	0111	1111	0001

The PE ignores the value of <Rt>. Software does not have to write a value to this register before issuing this instruction.

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	WO	n/a	WO
x	0	1	-	WO	WO	WO
x	1	1	-	n/a	WO	WO

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If HSTR_EL2.T7==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If [HSTR_EL2.T7](#)==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If [HSTR.T7](#)==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

G6.2.23 BPIMVA, Branch Predictor Invalidate by VA

The BPIMVA characteristics are:

Purpose

Invalidate virtual address from branch predictors.

Configurations

In an implementation where the branch predictors are architecturally invisible, this instruction can execute as a NOP.

Attributes

BPIMVA is a 32-bit System instruction.

Field descriptions

The BPIMVA input value bit assignments are:

Bits [31:0]

Virtual address to use.

Executing the BPIMVA instruction

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c7, c5, 7	000	111	0111	1111	0101

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	WO	n/a	WO
x	0	1	-	WO	WO	WO
x	1	1	-	n/a	WO	WO

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 0)$:
 - If $HSTR_EL2.T7 == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 1) \ \&\& \ (HCR_EL2.TGE == 0)$:
 - If $HSTR_EL2.T7 == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $HSTR.T7 == 1$, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

G6.2.24 CCSIDR, Current Cache Size ID Register

The CCSIDR characteristics are:

Purpose

Provides information about the architecture of the currently selected cache.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register CCSIDR is architecturally mapped to AArch64 System register [CCSIDR_EL1](#).

The implementation includes one CCSIDR for each cache that it can access. [CSSELR](#) and the Security state select which Cache Size ID Register is accessible.

Attributes

CCSIDR is a 32-bit register.

Field descriptions

The CCSIDR bit assignments are:

31	28 27	13 12	3 2 0
UNKNOWN	NumSets	Associativity	LineSize

UNKNOWN, bits [31:28]

Reserved, UNKNOWN.

NumSets, bits [27:13]

(Number of sets in cache) - 1, therefore a value of 0 indicates 1 set in the cache. The number of sets does not have to be a power of 2.

Associativity, bits [12:3]

(Associativity of cache) - 1, therefore a value of 0 indicates an associativity of 1. The associativity does not have to be a power of 2.

LineSize, bits [2:0]

($\text{Log}_2(\text{Number of bytes in cache line})$) - 4. For example:

For a line length of 16 bytes: $\text{Log}_2(16) = 4$, LineSize entry = 0. This is the minimum line length.

For a line length of 32 bytes: $\text{Log}_2(32) = 5$, LineSize entry = 1.

————— Note —————

The parameters NumSets, Associativity, and LineSize in these registers define the architecturally visible parameters that are required for the cache maintenance by Set/Way instructions. They are not guaranteed to represent the actual microarchitectural features of a design. You cannot make any inference about the actual sizes of caches based on these parameters.

Accessing the CCSIDR

This register can be read using MRC with the following syntax:

MRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 1, <Rt>, c0, c0, 0	001	000	0000	1111	0000

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	RO	n/a	RO
x	0	1	-	RO	RO	RO
x	1	1	-	n/a	RO	RO

If **CSSELR.Level** is programmed to a cache level that is not implemented, then on a read of the CCSIDR the behavior is CONstrained UNPREDICTABLE, and can be one of the following:

- The CCSIDR read is treated as NOP.
- The CCSIDR read is UNDEFINED.
- The CCSIDR read returns an UNKNOWN value.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If **HCR_EL2.TID2**==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If **HSTR_EL2.T0**==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If **HCR_EL2.TID2**==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If **HSTR_EL2.T0**==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If **HCR.TID2**==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
 - If **HSTR.T0**==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.

G6.2.25 CLIDR, Cache Level ID Register

The CLIDR characteristics are:

Purpose

Identifies the type of cache, or caches, that are implemented at each level and can be managed using the architected cache maintenance instructions that operate by set/way, up to a maximum of seven levels. Also identifies the Level of Coherence (LoC) and Level of Unification (LoU) for the cache hierarchy.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register CLIDR is architecturally mapped to AArch64 System register [CLIDR_EL1](#).

Attributes

CLIDR is a 32-bit register.

Field descriptions

The CLIDR bit assignments are:

31	30	29	27	26	24	23	21	20	18	17	15	14	12	11	9	8	6	5	3	2	0
ICB	LoUU	LoC	LoUIS	Ctype7	Ctype6	Ctype5	Ctype4	Ctype3	Ctype2	Ctype1											

ICB, bits [31:30]

Inner cache boundary. This field indicates the boundary for caching Inner Cacheable memory regions.

The possible values are:

00	Not disclosed by this mechanism.
01	L1 cache is the highest Inner Cacheable level.
10	L2 cache is the highest Inner Cacheable level.
11	L3 cache is the highest Inner Cacheable level.

LoUU, bits [29:27]

Level of Unification Uniprocessor for the cache hierarchy.

LoC, bits [26:24]

Level of Coherence for the cache hierarchy.

LoUIS, bits [23:21]

Level of Unification Inner Shareable for the cache hierarchy.

Ctype<n>, bits [3(n-1)+2:3(n-1)], for n = 1 to 7

Cache Type fields. Indicate the type of cache that is implemented and can be managed using the architected cache maintenance instructions that operate by set/way at each level, from Level 1 up to a maximum of seven levels of cache hierarchy. Possible values of each field are:

000	No cache.
001	Instruction cache only.
010	Data cache only.
011	Separate instruction and data caches.

100 Unified cache.

All other values are reserved.

If software reads the Cache Type fields from Ctype1 upwards, once it has seen a value of 000, no caches that can be managed using the architected cache maintenance instructions that operate by set/way exist at further-out levels of the hierarchy. So, for example, if Ctype3 is the first Cache Type field with a value of 000, the values of Ctype4 to Ctype7 must be ignored.

Accessing the CLIDR

This register can be read using MRC with the following syntax:

MRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 1, <Rt>, c0, c0, 1	001	001	0000	1111	0000

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	RO	n/a	RO
x	0	1	-	RO	RO	RO
x	1	1	-	n/a	RO	RO

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If HCR_EL2.TID2==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If HCR_EL2.TID2==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HCR.TID2==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
 - If HSTR.T0==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.

G6.2.26 CONTEXTIDR, Context ID Register

The CONTEXTIDR characteristics are:

Purpose

Identifies the current Process Identifier and, when using the Short-descriptor translation table format, the Address Space Identifier.

The value of the whole of this register is called the Context ID and is used by:

- The debug logic, for Linked and Unlinked Context ID matching.
- The trace logic, to identify the current process.

The significance of this register is for debug and trace use only.

Configurations

AArch32 System register CONTEXTIDR is architecturally mapped to AArch64 System register [CONTEXTIDR_ELI](#).

The register format depends on whether address translation is using the Long-descriptor or the Short-descriptor translation table format.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CONTEXTIDR is a 32-bit register.

Field descriptions

The CONTEXTIDR bit assignments are:

When *TTBCR.EAE*==0:

PROCID, bits [31:8]

Process Identifier. This field must be programmed with a unique value that identifies the current process.

ASID, bits [7:0]

Address Space Identifier. This field is programmed with the value of the current ASID.

When *TTBCR.EAE*==1:

PROCID, bits [31:0]

Process Identifier. This field must be programmed with a unique value that identifies the current process.

Accessing the CONTEXTIDR

This register can be read using MRC with the following syntax:

MCR <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c13, c0, 1	000	001	1101	1111	0000

Accessibility

The register is accessible in software as follows:

Configuration	Control			Accessibility				Instance
	E2H	TGE	NS	EL0	EL1	EL2	EL3	
EL3 is using AArch32.	x	0	1	-	RW	RW	RW	CONTEXTIDR_ns
EL3 is using AArch32.	x	1	1	-	n/a	RW	RW	CONTEXTIDR_ns
EL3 is using AArch32.	x	x	0	-	n/a	n/a	RW	CONTEXTIDR_s
EL3 is not implemented.	x	x	0	-	RW	n/a	n/a	CONTEXTIDR
EL3 is not implemented.	x	0	1	-	RW	RW	n/a	CONTEXTIDR
EL3 is not implemented.	x	1	1	-	n/a	RW	n/a	CONTEXTIDR
EL3 is using AArch64.	x	x	0	-	RW	n/a	n/a	CONTEXTIDR
EL3 is using AArch64.	x	0	1	-	RW	RW	n/a	CONTEXTIDR
EL3 is using AArch64.	x	1	1	-	n/a	RW	n/a	CONTEXTIDR

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If HCR_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
 - If HCR_EL2.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If HSTR_EL2.T13==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If HCR_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
 - If HCR_EL2.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If HSTR_EL2.T13==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HCR.TVM==1, Non-secure write accesses to this register from EL1 are trapped to Hyp mode.
 - If HCR.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.

- If `HSTR.T13==1`, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

G6.2.27 CP15DMB, Data Memory Barrier System instruction

The CP15DMB characteristics are:

Purpose

Performs a Data Memory Barrier.

ARM deprecates any use of this operation, and strongly recommends that software use the [DMB](#) instruction instead.

Configurations

There are no configuration notes.

Attributes

CP15DMB is a 32-bit System instruction.

Field descriptions

CP15DMB ignores the value in the register specified by the instruction. Software does not have to write a value to the register before issuing this instruction.

Executing the CP15DMB instruction

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c7, c10, 5	000	101	0111	1111	1010

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	WO	WO	n/a	WO
x	0	1	WO	WO	WO	WO
x	1	1	WO	n/a	WO	WO

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- In both security states, and not dependent on other bits:
 - If [SCTLR.CP15BEN](#)==0, execution of this instruction at PL0 and PL1 is UNDEFINED.
 - If [SCTLR_EL1.CP15BEN](#)==0, execution of this instruction at PL0 is UNDEFINED.
 - If [HSCTLR.CP15BEN](#)==0, execution of this instruction at PL2 is UNDEFINED.

- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 0)$:
 - If $HSTR_EL2.T7 == 1$, Non-secure execution of this instruction at EL0 and EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 1) \ \&\& \ (HCR_EL2.TGE == 0)$:
 - If $HSTR_EL2.T7 == 1$, Non-secure execution of this instruction at EL0 and EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $HSTR.T7 == 1$, Non-secure execution of this instruction at EL0 and EL1 is trapped to Hyp mode.

G6.2.28 CP15DSB, Data Synchronization Barrier System instruction

The CP15DSB characteristics are:

Purpose

Performs a Data Synchronization Barrier.

ARM deprecates any use of this operation, and strongly recommends that software use the [DSB](#) instruction instead.

Configurations

There are no configuration notes.

Attributes

CP15DSB is a 32-bit System instruction.

Field descriptions

CP15DSB ignores the value in the register specified by the instruction. Software does not have to write a value to the register before issuing this instruction.

Executing the CP15DSB instruction

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c7, c10, 4	000	100	0111	1111	1010

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	WO	WO	n/a	WO
x	0	1	WO	WO	WO	WO
x	1	1	WO	n/a	WO	WO

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- In both security states, and not dependent on other bits:
 - If `SCTLR.CP15BEN==0`, execution of this instruction at PL0 and PL1 is UNDEFINED.
 - If `SCTLR_EL1.CP15BEN==0`, execution of this instruction at PL0 is UNDEFINED.
 - If `HSCTLR.CP15BEN==0`, execution of this instruction at PL2 is UNDEFINED.

- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 0)$:
 - If $HSTR_EL2.T7 == 1$, Non-secure execution of this instruction at EL0 and EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 1) \ \&\& \ (HCR_EL2.TGE == 0)$:
 - If $HSTR_EL2.T7 == 1$, Non-secure execution of this instruction at EL0 and EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $HSTR.T7 == 1$, Non-secure execution of this instruction at EL0 and EL1 is trapped to Hyp mode.

G6.2.29 CP15ISB, Instruction Synchronization Barrier System instruction

The CP15ISB characteristics are:

Purpose

Performs an Instruction Synchronization Barrier.

ARM deprecates any use of this operation, and strongly recommends that software use the [ISB](#) instruction instead.

Configurations

There are no configuration notes.

Attributes

CP15ISB is a 32-bit System instruction.

Field descriptions

CP15ISB ignores the value in the register specified by the instruction. Software does not have to write a value to the register before issuing this instruction.

Executing the CP15ISB instruction

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c7, c5, 4	000	100	0111	1111	0101

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	WO	WO	n/a	WO
x	0	1	WO	WO	WO	WO
x	1	1	WO	n/a	WO	WO

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- In both security states, and not dependent on other bits:
 - If `SCTLR.CP15BEN==0`, execution of this instruction at PL0 and PL1 is UNDEFINED.
 - If `SCTLR_EL1.CP15BEN==0`, execution of this instruction at PL0 is UNDEFINED.
 - If `HSCTLR.CP15BEN==0`, execution of this instruction at PL2 is UNDEFINED.

- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 0)$:
 - If $HSTR_EL2.T7 == 1$, Non-secure execution of this instruction at EL0 and EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 1) \ \&\& \ (HCR_EL2.TGE == 0)$:
 - If $HSTR_EL2.T7 == 1$, Non-secure execution of this instruction at EL0 and EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $HSTR.T7 == 1$, Non-secure execution of this instruction at EL0 and EL1 is trapped to Hyp mode.

G6.2.30 CPACR, Architectural Feature Access Control Register

The CPACR characteristics are:

Purpose

Controls access to trace, and to Advanced SIMD and floating-point functionality from EL0, EL1, and EL3.

In an implementation that includes EL2, the CPACR has no effect on instructions executed at EL2.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register CPACR is architecturally mapped to AArch64 System register [CPACR_EL1](#).

Bits in the [NSACR](#) control Non-secure access to the CPACR fields. See the field descriptions for more information.

———— Note ————

In the register field descriptions, controls are described as applying at specified Privilege levels. This is because, in Secure state, a PL1 control:

- Applies to execution in a Secure EL3 mode when EL3 is using AArch32.
- Applies to execution in a Secure EL1 mode when EL3 is using AArch64.

See [Security state, Exception levels, and AArch32 execution privilege on page G1-4318](#).

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into an Exception level that is using AArch32. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CPACR is a 32-bit register.

Field descriptions

The CPACR bit assignments are:

ASEDIS, bit [31]

Disables PL0 and PL1 execution of Advanced SIMD instructions.

0 This control permits execution of Advanced SIMD instructions at PL0 and PL1.

1 All instruction encodings that are Advanced SIMD instruction encodings, but are not also floating-point instruction encodings, are UNDEFINED at PL0 and PL1.

If the implementation does not include Advanced SIMD and floating-point functionality, this field is RES0. Otherwise, it is IMPLEMENTATION DEFINED whether this field is implemented as a RW field. If it is not implemented as a RW field, it is RAZ/WI.

If EL3 is implemented and is using AArch32, and the value of [NSACR.NSASEDIS](#) is 1, this field behaves as RAO/WI in Non-secure state, regardless of its actual value. This applies even if the field is implemented as RAZ/WI.

For the list of instructions affected by this field, see *Controls of Advanced SIMD operation that do not apply to floating-point operation* on page E1-2746.

See the description of CPACR.cp10 for a list of other controls that can disable or trap execution of Advanced SIMD instructions in AArch32 state.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to 0.

Bits [30:29]

Reserved, RES0.

TRCDIS, bit [28]

Traps PL0 and PL1 System register accesses to all implemented trace registers to Undefined mode.

- | | |
|---|--|
| 0 | This control has no effect on PL0 and PL1 System register accesses to trace registers. |
| 1 | PL0 and PL1 System register accesses to all implemented trace registers are trapped to Undefined mode. |

If the implementation does not include a trace macrocell, or does not include a System register interface to the trace macrocell registers, this field is RES0. Otherwise, it is IMPLEMENTATION DEFINED whether this field is implemented as a RW field. If it is not implemented as a RW field, it is RAZ/WI.

If EL3 is implemented and is using AArch32, and the value of NSACR.NSTRCDIS is 1, this field behaves as RAO/WI in Non-secure state, regardless of its actual value. This applies even if the field is implemented as RAZ/WI.

Note

- The ETMv4 architecture does not permit EL0 to access the trace registers. If the implementation includes an ETMv4 implementation, EL0 accesses to the trace registers are UNDEFINED.
- The architecture does not provide traps on trace register accesses through the optional memory-mapped external debug interface.

System register accesses to the trace registers can have side-effects. When a System register access is trapped, any side-effects that are normally associated with the access do not occur before the exception is taken.

If this field is implemented as an RW field, it resets to a value that is architecturally UNKNOWN.

Bits [27:24]

Reserved, RES0.

cp11, bits [23:22]

The value of this field is ignored. If this field is programmed with a different value to the cp10 field then this field is UNKNOWN on a direct read of the CPACR.

If the implementation does not include Advanced SIMD and floating-point functionality, this field is RES0.

In Non-secure state, if EL3 is implemented and is using AArch32, when the value of NSACR.cp10 is 0, this field behaves as RAZ/WI, regardless of its actual value.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to 0.

cp10, bits [21:20]

Defines the access rights for the floating-point and Advanced SIMD functionality. Possible values of the field are:

- | | |
|----|---|
| 00 | PL0 and PL1 accesses to floating-point and Advanced SIMD registers or instructions are UNDEFINED. |
|----|---|

- 01 PL0 accesses to floating-point and Advanced SIMD registers or instructions are UNDEFINED.
- 10 Reserved. The effect of programming this field to this value is CONSTRAINED UNPREDICTABLE. See *Reserved values in System and memory-mapped registers and translation table entries* on page K1-6117.
- 11 This control permits full access to the floating-point and Advanced SIMD functionality from PL0 and PL1.

The floating-point and Advanced SIMD features controlled by these fields are:

- Execution of any floating-point or Advanced SIMD instruction.
- Any access to the Advanced SIMD and floating-point registers D0-D31 and their views as S0-S31 and Q0-Q15.
- Any access to the [FPSCR](#), [FPSID](#), [MVFRO](#), [MVFRI](#), [MVFR2](#), or [FPEXC](#) System registers.

———— **Note** ————

The [CPACR](#) has no effect on floating-point and Advanced SIMD accesses from PL2. These can be disabled by the [HCPTR.TCP10](#) field.

If the implementation does not include Advanced SIMD and floating-point functionality, this field is RES0.

In Non-secure state, if EL3 is implemented and is using AArch32, when the value of [NSACR.cp10](#) is 0, this field behaves as RAZ/WI, regardless of its actual value.

Execution of floating-point and Advanced SIMD instructions in AArch32 state can be disabled or trapped by the following controls:

- [CPACR.cp10](#), or, if executing at EL0, [CPACR_EL1.FPEN](#).
- [FPEXC.EN](#).
- If executing in Non-secure state:
 - [HCPTR.TCP10](#), or if EL2 is using AArch64, [CPTR_EL2.TFP](#).
 - [NSACR.cp10](#), or if EL3 is using AArch64, [CPTR_EL3.TFP](#).
- For Advanced SIMD instructions only:
 - [CPACR.ASEDIS](#).
 - If executing in Non-secure state, [HCPTR.TASE](#) and [NSACR.NSTRCDIS](#).

See the descriptions of the controls for more information.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to 0.

Bits [19:0]

Reserved, RES0.

Accessing the CPACR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c1, c0, 2	000	010	0001	1111	0000

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	RW	n/a	RW
x	0	1	-	RW	RW	RW
x	1	1	-	n/a	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 0)$:
 - If $CPTR_EL2.TCPAC == 1$, Non-secure accesses to this register from EL1 are trapped to EL2.
 - If $HSTR_EL2.T1 == 1$, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 1) \ \&\& \ (HCR_EL2.TGE == 0)$:
 - If $CPTR_EL2.TCPAC == 1$, Non-secure accesses to this register from EL1 are trapped to EL2.
 - If $HSTR_EL2.T1 == 1$, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $HCPTR.TCPAC == 1$, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
 - If $HSTR.T1 == 1$, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
- When EL3 is implemented and is using AArch64:
 - If $CPTR_EL3.TCPAC == 1$, accesses to this register from EL1 and EL2 are trapped to EL3.

G6.2.31 CPSR, Current Program Status Register

The CPSR characteristics are:

Purpose

Holds PE status and control information.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

Attributes

CPSR is a 32-bit register.

Field descriptions

The CPSR bit assignments are:

N, bit [31]

Negative condition flag. Set to bit[31] of the result of the last flag-setting instruction. If the result is regarded as a two's complement signed integer, then N is set to 1 if the result was negative, and N is set to 0 if the result was positive or zero.

Z, bit [30]

Zero condition flag. Set to 1 if the result of the last flag-setting instruction was zero, and to 0 otherwise. A result of zero often indicates an equal result from a comparison.

C, bit [29]

Carry condition flag. Set to 1 if the last flag-setting instruction resulted in a carry condition, for example an unsigned overflow on an addition.

V, bit [28]

Overflow condition flag. Set to 1 if the last flag-setting instruction resulted in an overflow condition, for example a signed overflow on an addition.

Q, bit [27]

Cumulative saturation bit. Set to 1 to indicate that overflow or saturation occurred in some instructions.

IT[1:0], bits [26:25]

IT block state bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

J, bit [24]

RES0.

In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state. ARMv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

Bit [23]

Reserved, RES0.

PAN, bit [22]

In ARMv8.2 and ARMv8.1

Privileged Access Never. When [ARMv8.1-PAN](#) is implemented, defined values are:

- 0 The translation system is the same as ARMv8.0.
- 1 Disables privileged read and write accesses to addresses accessible at EL0.

The value of this bit is usually preserved on taking an exception, except in the following situations:

- When the target of the exception is EL1, and the value of the [SCTLR.SPAN](#) bit for the current Security state is 0, this bit is set to 1.
- When the target of the exception is EL3, from Secure state, and the value of the Secure [SCTLR.SPAN](#) is 0, this bit is set to 1.
- When the target of the exception is EL3, from Non-secure state, this bit is set to 0 regardless of the value of the Secure [SCTLR.SPAN](#) bit.

When [ARMv8.1-PAN](#) is not implemented, this bit is RES0.

In ARMv8.0.

Reserved, RES0.

Bits [21:20]

Reserved, RES0.

GE, bits [19:16]

Greater than or Equal flags, for parallel addition and subtraction.

IT[7:2], bits [15:10]

IT block state bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is 0b00000000 when no IT block is active.

E, bit [9]

Endianness state bit. Controls the load and store endianness for data accesses:

- 0 Little-endian operation
- 1 Big-endian operation.

Instruction fetches ignore this bit.

When the reset value of the [SCTLR.EE](#) bit is defined by a configuration input signal, that value also applies to the [CPSR.E](#) bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any Exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any Exception level other than EL0.

A, bit [8]

SERror interrupt mask bit. The possible values of this bit are:

- 0 Exception not masked.

1 Exception masked.

I, bit [7]

IRQ mask bit. The possible values of this bit are:

0 Exception not masked.
 1 Exception masked.

F, bit [6]

FIQ mask bit. The possible values of this bit are:

0 Exception not masked.
 1 Exception masked.

T, bit [5]

T32 Instruction set state bit. Indicates the AArch32 instruction set state. Possible values of this bit are:

0 A32 state.
 1 T32 state.

Bit [4]

Reserved, RES1.

M[3:0], bits [3:0]

Current PE mode. Possible values are:

M[3:0]	Mode
0b0000	User
0b0001	FIQ
0b0010	IRQ
0b0011	Supervisor
0b0110	Monitor
0b0111	Abort
0b1010	Hyp
0b1011	Undefined
0b1111	System

Other values are reserved.

G6.2.32 CSSELR, Cache Size Selection Register

The CSSELR characteristics are:

Purpose

Selects the current Cache Size ID Register, [CCSIDR](#), by specifying the required cache level and the cache type (either instruction or data cache).

Configurations

AArch32 System register CSSELR is architecturally mapped to AArch64 System register [CSSELR_EL1](#).

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CSSELR is a 32-bit register.

Field descriptions

The CSSELR bit assignments are:

Bits [31:4]

Reserved, RES0.

Level, bits [3:1]

Cache level of required cache. Permitted values are:

000	Level 1 cache
001	Level 2 cache
010	Level 3 cache
011	Level 4 cache
100	Level 5 cache
101	Level 6 cache
110	Level 7 cache

All other values are reserved.

If CSSELR.Level is programmed to a cache level that is not implemented, then the value for this field on a read of CSSELR is UNKNOWN.

InD, bit [0]

Instruction not Data bit. Permitted values are:

0	Data or unified cache.
1	Instruction cache.

If CSSELR.Level is programmed to a cache level that is not implemented, then the value for this field on a read of CSSELR is UNKNOWN.

Accessing the CSSELR

This register can be read using MRC with the following syntax:

MCR <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 2, <Rt>, c0, c0, 0	010	000	0000	1111	0000

Accessibility

The register is accessible in software as follows:

Configuration	Control			Accessibility				Instance
	E2H	TGE	NS	EL0	EL1	EL2	EL3	
EL3 is not implemented.	x	x	0	-	RW	n/a	n/a	CSSELR
EL3 is not implemented.	x	0	1	-	RW	RW	n/a	CSSELR
EL3 is not implemented.	x	1	1	-	n/a	RW	n/a	CSSELR
EL3 is using AArch64.	x	x	0	-	RW	n/a	n/a	CSSELR
EL3 is using AArch64.	x	0	1	-	RW	RW	n/a	CSSELR
EL3 is using AArch64.	x	1	1	-	n/a	RW	n/a	CSSELR
EL3 is using AArch32.	x	x	0	-	n/a	n/a	RW	CSSELR_s
EL3 is using AArch32.	x	0	1	-	RW	RW	RW	CSSELR_ns
EL3 is using AArch32.	x	1	1	-	n/a	RW	RW	CSSELR_ns

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If HCR_EL2.TID2==1, Non-secure accesses to this register from EL1 are trapped to EL2.
 - If HSTR_EL2.T0==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If HCR_EL2.TID2==1, Non-secure accesses to this register from EL1 are trapped to EL2.
 - If HSTR_EL2.T0==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HCR.TID2==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
 - If HSTR.T0==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

G6.2.33 CTR, Cache Type Register

The CTR characteristics are:

Purpose

Provides information about the architecture of the caches.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register CTR is architecturally mapped to AArch64 System register [CTR_EL0](#).

Attributes

CTR is a 32-bit register.

Field descriptions

The CTR bit assignments are:

Bit [31]

Reserved, RES1.

Bits [30:28]

Reserved, RES0.

CWG, bits [27:24]

Cache writeback granule. \log_2 of the number of words of the maximum size of memory that can be overwritten as a result of the eviction of a cache entry that has had a memory location in it modified.

A value of `0b0000` indicates that this register does not provide Cache writeback granule information and either:

- The architectural maximum of 512 words (2KB) must be assumed.
- The Cache writeback granule can be determined from maximum cache line size encoded in the Cache Size ID Registers.

Values greater than `0b1001` are reserved.

ARM recommends that an implementation that does not support cache write-back implements this field as `0b0001`. This applies, for example, to an implementation that supports only write-through caches.

ERG, bits [23:20]

Exclusives reservation granule. \log_2 of the number of words of the maximum size of the reservation granule that has been implemented for the Load-Exclusive and Store-Exclusive instructions.

A value of `0b0000` indicates that this register does not provide Exclusives reservation granule information and the architectural maximum of 512 words (2KB) must be assumed.

Values greater than `0b1001` are reserved.

DminLine, bits [19:16]

\log_2 of the number of words in the smallest cache line of all the data caches and unified caches that are controlled by the PE.

L1Ip, bits [15:14]

Level 1 instruction cache policy. Indicates the indexing and tagging policy for the L1 instruction cache. Possible values of this field are:

- 00 VMID aware Physical Index, Physical tag (VPIPT)
- 01 ASID-tagged Virtual Index, Virtual Tag (AIVIVT)
- 10 Virtual Index, Physical Tag (VIPT)
- 11 Physical Index, Physical Tag (PIPT)

The value 0b01 is reserved in ARMv8.

Bits [13:4]

Reserved, RES0.

IminLine, bits [3:0]

Log₂ of the number of words in the smallest cache line of all the instruction caches that are controlled by the PE.

Accessing the CTR

This register can be read using MRC with the following syntax:

MRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c0, c0, 1	000	001	0000	1111	0000

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	RO	n/a	RO
x	0	1	-	RO	RO	RO
x	1	1	-	n/a	RO	RO

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If HCR_EL2.TID2==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If HCR_EL2.TID2==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HCR.TID2==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
 - If HSTR.T0==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.

G6.2.34 DACR, Domain Access Control Register

The DACR characteristics are:

Purpose

Defines the access permission for each of the sixteen memory domains.

Configurations

AArch32 System register DACR is architecturally mapped to AArch64 System register [DACR32_EL2](#).

When EL3 is using AArch32, write access to DACR(S) is disabled when the CP15SDISABLE signal is asserted HIGH.

This register has no function when [TTBCR.EAE](#) is set to 1, to select the Long-descriptor translation table format.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

DACR is a 32-bit register.

Field descriptions

The DACR bit assignments are:

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
D15	D14	D13	D12	D11	D10	D9	D8	D7	D6	D5	D4	D3	D2	D1	D0																

D<n>, bits [2n+1:2n], for n = 0 to 15

Domain n access permission, where n = 0 to 15. Permitted values are:

- 00 No access. Any access to the domain generates a Domain fault.
 - 01 Client. Accesses are checked against the permission bits in the translation tables.
 - 11 Manager. Accesses are not checked against the permission bits in the translation tables.
- The value 10 is reserved.

Accessing the DACR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c3, c0, 0	000	000	0011	1111	0000

Accessibility

The register is accessible in software as follows:

Configuration	Control			Accessibility				Instance
	E2H	TGE	NS	EL0	EL1	EL2	EL3	
EL3 is not implemented.	x	x	0	-	RW	n/a	n/a	DACR
EL3 is not implemented.	x	0	1	-	RW	RW	n/a	DACR
EL3 is not implemented.	x	1	1	-	n/a	RW	n/a	DACR
EL3 is using AArch64.	x	x	0	-	RW	n/a	n/a	DACR
EL3 is using AArch64.	x	0	1	-	RW	RW	n/a	DACR
EL3 is using AArch64.	x	1	1	-	n/a	RW	n/a	DACR
EL3 is using AArch32.	x	x	0	-	n/a	n/a	RW	DACR_s
EL3 is using AArch32.	x	0	1	-	RW	RW	RW	DACR_ns
EL3 is using AArch32.	x	1	1	-	n/a	RW	RW	DACR_ns

When EL3 is using AArch32, write access to DACR_s is UNDEFINED when the CP15SDISABLE signal is asserted HIGH.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If HCR_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
 - If HCR_EL2.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If HSTR_EL2.T3==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If HCR_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
 - If HCR_EL2.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If HSTR_EL2.T3==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HCR.TVM==1, Non-secure write accesses to this register from EL1 are trapped to Hyp mode.
 - If HCR.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
 - If HSTR.T3==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

G6.2.35 DCCIMVAC, Data Cache line Clean and Invalidate by VA to PoC

The DCCIMVAC characteristics are:

Purpose

Clean and Invalidate data or unified cache line by virtual address to PoC.

Configurations

AArch32 System instruction DCCIMVAC performs the same function as AArch64 System instruction [DC CIVAC](#).

Attributes

DCCIMVAC is a 32-bit System instruction.

Field descriptions

The DCCIMVAC input value bit assignments are:

Bits [31:0]

Virtual address to use.

Executing the DCCIMVAC instruction

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c7, c14, 1	000	001	0111	1111	1110

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	WO	n/a	WO
x	0	1	-	WO	WO	WO
x	1	1	-	n/a	WO	WO

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \&\& (HCR_EL2.E2H == 0)$:
 - If $HCR_EL2.TPC == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
 - If $HSTR_EL2.T7 == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \&\& (HCR_EL2.E2H == 1) \&\& (HCR_EL2.TGE == 0)$:
 - If $HCR_EL2.TPC == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
 - If $HSTR_EL2.T7 == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $HCR.TPC == 1$, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
 - If $HSTR.T7 == 1$, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

G6.2.36 DCCISW, Data Cache line Clean and Invalidate by Set/Way

The DCCISW characteristics are:

Purpose

Clean and Invalidate data or unified cache line by set/way.

Configurations

AArch32 System instruction DCCISW performs the same function as AArch64 System instruction [DC C1SW](#).

Attributes

DCCISW is a 32-bit System instruction.

Field descriptions

The DCCISW input value bit assignments are:

SetWay, bits [31:4]

Contains two fields:

- Way, bits[31:32-A], the number of the way to operate on.
- Set, bits[B-1:L], the number of the set to operate on.

Bits[L-1:4] are RES0.

$A = \text{Log}_2(\text{ASSOCIATIVITY})$, $L = \text{Log}_2(\text{LINELEN})$, $B = (L + S)$, $S = \text{Log}_2(\text{NSETS})$.

ASSOCIATIVITY, LINELEN (line length, in bytes), and NSETS (number of sets) have their usual meanings and are the values for the cache level being operated on. The values of A and S are rounded up to the next integer.

Level, bits [3:1]

Cache level to operate on, minus 1. For example, this field is 0 for operations on L1 cache, or 1 for operations on L2 cache.

Bit [0]

Reserved, RES0.

Executing the DCCISW instruction

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c7, c14, 2	000	010	0111	1111	1110

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	WO	n/a	WO
x	0	1	-	WO	WO	WO
x	1	1	-	n/a	WO	WO

If this instruction is executed with a set, way or level argument that is larger than the value supported by the implementation then the behavior is CONstrained UNPREDICTABLE and one of the following occurs:

- The instruction is UNDEFINED
- The instruction performs cache maintenance on one of:
 - No cache lines.
 - A single arbitrary cache line.
 - Multiple arbitrary cache lines.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If HCR_EL2.TSW==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
 - If HSTR_EL2.T7==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If HCR_EL2.TSW==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
 - If HSTR_EL2.T7==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HCR.TSW==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
 - If HSTR.T7==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

G6.2.37 DCCMVAC, Data Cache line Clean by VA to PoC

The DCCMVAC characteristics are:

Purpose

Clean data or unified cache line by virtual address to PoC.

Configurations

AArch32 System instruction DCCMVAC performs the same function as AArch64 System instruction [DC CVAC](#).

Attributes

DCCMVAC is a 32-bit System instruction.

Field descriptions

The DCCMVAC input value bit assignments are:

Bits [31:0]

Virtual address to use.

Executing the DCCMVAC instruction

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c7, c10, 1	000	001	0111	1111	1010

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	WO	n/a	WO
x	0	1	-	WO	WO	WO
x	1	1	-	n/a	WO	WO

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \&\& (HCR_EL2.E2H == 0)$:
 - If $HCR_EL2.TPC == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
 - If $HSTR_EL2.T7 == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \&\& (HCR_EL2.E2H == 1) \&\& (HCR_EL2.TGE == 0)$:
 - If $HCR_EL2.TPC == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
 - If $HSTR_EL2.T7 == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $HCR.TPC == 1$, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
 - If $HSTR.T7 == 1$, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

G6.2.38 DCCMVAU, Data Cache line Clean by VA to PoU

The DCCMVAU characteristics are:

Purpose

Clean data or unified cache line by virtual address to PoU.

Configurations

AArch32 System instruction DCCMVAU performs the same function as AArch64 System instruction [DC CVAU](#).

Attributes

DCCMVAU is a 32-bit System instruction.

Field descriptions

The DCCMVAU input value bit assignments are:

Bits [31:0]

Virtual address to use.

Executing the DCCMVAU instruction

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c7, c11, 1	000	001	0111	1111	1011

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	WO	n/a	WO
x	0	1	-	WO	WO	WO
x	1	1	-	n/a	WO	WO

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \&\& (HCR_EL2.E2H == 0)$:
 - If $HCR_EL2.TPU == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
 - If $HSTR_EL2.T7 == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \&\& (HCR_EL2.E2H == 1) \&\& (HCR_EL2.TGE == 0)$:
 - If $HCR_EL2.TPU == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
 - If $HSTR_EL2.T7 == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $HCR.TPU == 1$, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
 - If $HSTR.T7 == 1$, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

G6.2.39 DCCSW, Data Cache line Clean by Set/Way

The DCCSW characteristics are:

Purpose

Clean data or unified cache line by set/way.

Configurations

AArch32 System instruction DCCSW performs the same function as AArch64 System instruction [DC CSW](#).

Attributes

DCCSW is a 32-bit System instruction.

Field descriptions

The DCCSW input value bit assignments are:

SetWay, bits [31:4]

Contains two fields:

- Way, bits[31:32-A], the number of the way to operate on.
- Set, bits[B-1:L], the number of the set to operate on.

Bits[L-1:4] are RES0.

$A = \text{Log}_2(\text{ASSOCIATIVITY})$, $L = \text{Log}_2(\text{LINELEN})$, $B = (L + S)$, $S = \text{Log}_2(\text{NSETS})$.

ASSOCIATIVITY, LINELEN (line length, in bytes), and NSETS (number of sets) have their usual meanings and are the values for the cache level being operated on. The values of A and S are rounded up to the next integer.

Level, bits [3:1]

Cache level to operate on, minus 1. For example, this field is 0 for operations on L1 cache, or 1 for operations on L2 cache.

Bit [0]

Reserved, RES0.

Executing the DCCSW instruction

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c7, c10, 2	000	010	0111	1111	1010

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	WO	n/a	WO
x	0	1	-	WO	WO	WO
x	1	1	-	n/a	WO	WO

If this instruction is executed with a set, way or level argument that is larger than the value supported by the implementation then the behavior is CONstrained UNPREDICTABLE and one of the following occurs:

- The instruction is UNDEFINED
- The instruction performs cache maintenance on one of:
 - No cache lines.
 - A single arbitrary cache line.
 - Multiple arbitrary cache lines.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If HCR_EL2.TSW==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
 - If HSTR_EL2.T7==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If HCR_EL2.TSW==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
 - If HSTR_EL2.T7==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HCR.TSW==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
 - If HSTR.T7==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

G6.2.40 DCIMVAC, Data Cache line Invalidate by VA to PoC

The DCIMVAC characteristics are:

Purpose

Invalidate data or unified cache line by virtual address to PoC.

Configurations

AArch32 System instruction DCIMVAC performs the same function as AArch64 System instruction [DC IVAC](#).

Attributes

DCIMVAC is a 32-bit System instruction.

Field descriptions

The DCIMVAC input value bit assignments are:

Bits [31:0]

Virtual address to use.

Executing the DCIMVAC instruction

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c7, c6, 1	000	001	0111	1111	0110

It is IMPLEMENTATION DEFINED whether, when this instruction is executed, it can generate a watchpoint. If this instruction can generate a watchpoint this is prioritized in the same way as other watchpoints.

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	WO	n/a	WO
x	0	1	-	WO	WO	WO
x	1	1	-	n/a	WO	WO

At EL1, this instruction performs a cache clean and invalidate, meaning it performs the same invalidation as a [DCCIMVAC](#) instruction, if all of the following apply:

- EL2 is implemented and either:
 - EL2 is using AArch64 and the value of [HCR_EL2.VM](#) is 1.
 - EL2 is using AArch32 and the value of [HCR.VM](#) is 1.
- Execution is in Non-secure state, or EL3 is not implemented.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \&\& (HCR_EL2.E2H == 0)$:
 - If [HCR_EL2.TPC](#)==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
 - If [HSTR_EL2.T7](#)==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \&\& (HCR_EL2.E2H == 1) \&\& (HCR_EL2.TGE == 0)$:
 - If [HCR_EL2.TPC](#)==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
 - If [HSTR_EL2.T7](#)==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If [HCR.TPC](#)==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
 - If [HSTR.T7](#)==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

G6.2.41 DCISW, Data Cache line Invalidate by Set/Way

The DCISW characteristics are:

Purpose

Invalidate data or unified cache line by set/way.

Configurations

AArch32 System instruction DCISW performs the same function as AArch64 System instruction [DC ISW](#).

Attributes

DCISW is a 32-bit System instruction.

Field descriptions

The DCISW input value bit assignments are:

SetWay, bits [31:4]

Contains two fields:

- Way, bits[31:32-A], the number of the way to operate on.
- Set, bits[B-1:L], the number of the set to operate on.

Bits[L-1:4] are RES0.

$A = \text{Log}_2(\text{ASSOCIATIVITY})$, $L = \text{Log}_2(\text{LINELEN})$, $B = (L + S)$, $S = \text{Log}_2(\text{NSETS})$.

ASSOCIATIVITY, LINELEN (line length, in bytes), and NSETS (number of sets) have their usual meanings and are the values for the cache level being operated on. The values of A and S are rounded up to the next integer.

Level, bits [3:1]

Cache level to operate on, minus 1. For example, this field is 0 for operations on L1 cache, or 1 for operations on L2 cache.

Bit [0]

Reserved, RES0.

Executing the DCISW instruction

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c7, c6, 2	000	010	0111	1111	0110

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	WO	n/a	WO
x	0	1	-	WO	WO	WO
x	1	1	-	n/a	WO	WO

At EL1, this instruction performs a cache clean and invalidate, meaning it performs the same invalidation as a [DCCISW](#) instruction, if all of the following apply:

- EL2 is implemented and either:
 - EL2 is using AArch64 and the value of [HCR_EL2](#).{SWIO, VM} is not {0, 0}.
 - EL2 is using AArch32 and the value of [HCR](#).{SWIO, VM} is not {0, 0}.
- Execution is in Non-secure state, or EL3 is not implemented.

If this instruction is executed with a set, way or level argument that is larger than the value supported by the implementation then the behavior is CONstrained UNPREDICTABLE and one of the following occurs:

- The instruction is UNDEFINED
- The instruction performs cache maintenance on one of:
 - No cache lines.
 - A single arbitrary cache line.
 - Multiple arbitrary cache lines.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If [HCR_EL2](#).TSW==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
 - If [HSTR_EL2](#).T7==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If [HCR_EL2](#).TSW==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
 - If [HSTR_EL2](#).T7==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If [HCR](#).TSW==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
 - If [HSTR](#).T7==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

G6.2.42 DFAR, Data Fault Address Register

The DFAR characteristics are:

Purpose

Holds the virtual address of the faulting address that caused a synchronous Data Abort exception.

Configurations

AArch32 System register DFAR(NS) is architecturally mapped to AArch64 System register [FAR_EL1](#)[31:0].

AArch32 System register DFAR(S) is architecturally mapped to AArch32 System register [HDFAR](#) when EL2 is implemented.

AArch32 System register DFAR(S) is architecturally mapped to AArch64 System register [FAR_EL2](#)[31:0] when EL2 is implemented.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

DFAR is a 32-bit register.

Field descriptions

The DFAR bit assignments are:

Bits [31:0]

VA of faulting address of synchronous Data Abort exception.

Accessing the DFAR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c6, c0, 0	000	000	0110	1111	0000

Accessibility

The register is accessible in software as follows:

Configuration	Control			Accessibility				Instance
	E2H	TGE	NS	EL0	EL1	EL2	EL3	
EL3 is using AArch32.	x	x	0	-	n/a	n/a	RW	DFAR_s
EL3 is not implemented.	x	x	0	-	RW	n/a	n/a	DFAR
EL3 is not implemented.	x	0	1	-	RW	RW	n/a	DFAR
EL3 is not implemented.	x	1	1	-	n/a	RW	n/a	DFAR
EL3 is using AArch64.	x	x	0	-	RW	n/a	n/a	DFAR
EL3 is using AArch64.	x	0	1	-	RW	RW	n/a	DFAR
EL3 is using AArch64.	x	1	1	-	n/a	RW	n/a	DFAR
EL3 is using AArch32.	x	0	1	-	RW	RW	RW	DFAR_ns
EL3 is using AArch32.	x	1	1	-	n/a	RW	RW	DFAR_ns

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If HCR_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
 - If HCR_EL2.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If HSTR_EL2.T6==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If HCR_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
 - If HCR_EL2.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If HSTR_EL2.T6==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HCR.TVM==1, Non-secure write accesses to this register from EL1 are trapped to Hyp mode.
 - If HCR.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
 - If HSTR.T6==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

G6.2.43 DFSR, Data Fault Status Register

The DFSR characteristics are:

Purpose

Holds status information about the last data fault.

Configurations

AArch32 System register DFSR is architecturally mapped to AArch64 System register [ESR_EL1](#).

The current translation table format determines which format of the register is used.

RW fields in this register reset to architecturally UNKNOWN values.

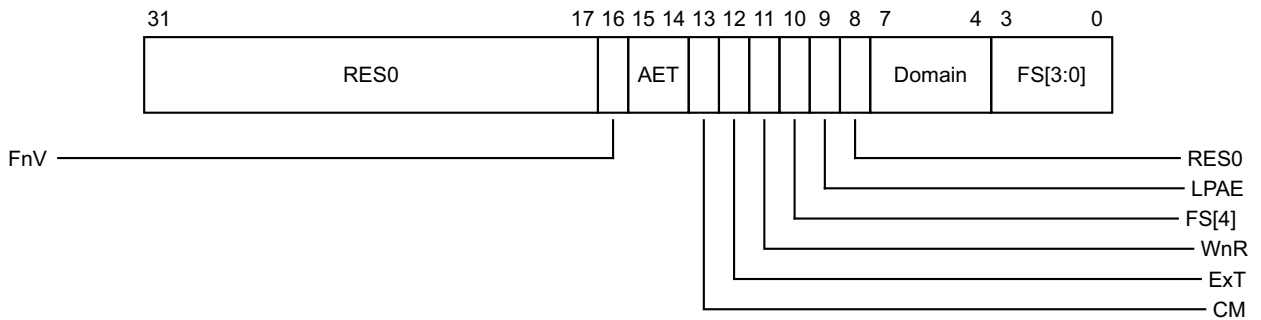

Attributes

DFSR is a 32-bit register.

Field descriptions

The DFSR bit assignments are:

When *TTBCR.EAE*==0:

Bits [31:17]

Reserved, RES0.

FnV, bit [16]

FAR not Valid, for a Synchronous external abort other than a Synchronous external abort on a translation table walk.

- 0 [DFAR](#) is valid.
- 1 [DFAR](#) is not valid, and holds an UNKNOWN value.

This field is only valid for a Synchronous external abort other than a Synchronous external abort on a translation table walk. It is RES0 for all other Data Abort exceptions.

AET, bits [15:14]

Asynchronous Error Type. When the RAS Extension is implemented, this field describes the state of the PE after taking an asynchronous Data Abort exception. Possible values are:

- 00 Uncontainable error (UC) or uncategorized.
- 01 Unrecoverable error (UEU).
- 10 Restartable error (UEO) or Corrected error (CE).
- 11 Recoverable error (UER).

When the RAS Extension is not implemented, or on a synchronous Data Abort, this field is RES0.

———— **Note** —————

ARMv8.2 requires the implementation of the RAS Extension.

In the event of multiple errors taken as a single SError interrupt exception, the overall state of the PE is reported.

———— **Note** —————

Software can use this information to determine what recovery might be possible. The recovery software must also examine any implemented fault records to determine the location and extent of the error.

CM, bit [13]

Cache maintenance fault. For synchronous faults, this bit indicates whether a cache maintenance instruction generated the fault. The possible values of this bit are:

- 0 Abort not caused by execution of a cache maintenance instruction.
- 1 Abort caused by execution of a cache maintenance instruction.

On a synchronous Data Abort on a translation table walk, this bit is UNKNOWN.

On an asynchronous fault, this bit is UNKNOWN.

Ext, bit [12]

External abort type. This bit can be used to provide an IMPLEMENTATION DEFINED classification of external aborts.

In an implementation that does not provide any classification of external aborts, this bit is RES0.

For aborts other than external aborts this bit always returns 0.

WnR, bit [11]

Write not Read bit. Indicates whether the abort was caused by a write or a read instruction. The possible values of this bit are:

- 0 Abort caused by a read instruction.
- 1 Abort caused by a write instruction.

For faults on the cache maintenance and address translation System instructions in the (coproc==1111) encoding space this bit always returns a value of 1.

FS[4], bit [10]

See FS[3:0], bits [3:0] for description of the FS field.

LPAE, bit [9]

On taking a Data Abort exception, this bit is set as follows:

- 0 Using the Short-descriptor translation table formats.
- 1 Using the Long-descriptor translation table formats.

Hardware does not interpret this bit to determine the behavior of the memory system, and therefore software can set this bit to 0 or 1 without affecting operation.

Bit [8]

Reserved, RES0.

Domain, bits [7:4]

The domain of the fault address.

ARM deprecates any use of this field, see [The Domain field in the DFSR on page G4-4669](#).

This field is UNKNOWN for certain faults where the DFSR is updated and reported using the Short-descriptor FSR encodings, see [Table G4-29 on page G4-4673](#).

FS[3:0], bits [3:0]

Fault status bits. Interpreted with bit [10]. Possible values of FS[4:0] are:

- 00001 Alignment fault
- 00010 Debug exception
- 00011 Access flag fault, level 1
- 00100 Fault on instruction cache maintenance
- 00101 Translation fault, level 1
- 00110 Access flag fault, level 2
- 00111 Translation fault, level 2
- 01000 Synchronous external abort, not on translation table walk
- 01001 Domain fault, level 1
- 01011 Domain fault, level 2
- 01100 Synchronous external abort, on translation table walk, level 1
- 01101 Permission fault, level 1
- 01110 Synchronous external abort, on translation table walk, level 2
- 01111 Permission fault, level 2
- 10000 TLB conflict abort
- 10100 IMPLEMENTATION DEFINED fault (Lockdown fault)
- 10101 IMPLEMENTATION DEFINED fault (Unsupported Exclusive access fault)
- 10110 SError interrupt
- 11000 SError interrupt, from a parity or ECC error on memory access
- 11001 Synchronous parity or ECC error on memory access, not on translation table walk
- 11100 Synchronous parity or ECC error on translation table walk, level 1
- 11110 Synchronous parity or ECC error on translation table walk, level 2

All other values are reserved.

When the RAS Extension is implemented, 11000, 11001, 11100, and 11110 are reserved.

For more information about the lookup level associated with a fault, see [The level associated with MMU faults on a Short-descriptor translation table lookup](#) on page G4-4669.

When TTBCR.EAE==1:

Bits [31:17]

Reserved, RES0.

FnV, bit [16]

FAR not Valid, for a Synchronous external abort other than a Synchronous external abort on a translation table walk.

- 0 DFAR is valid.
- 1 DFAR is not valid, and holds an UNKNOWN value.

This field is only valid for a Synchronous external abort other than a Synchronous external abort on a translation table walk. It is RES0 for all other Data Abort exceptions.

AET, bits [15:14]

Asynchronous Error Type. When the RAS Extension is implemented, this field describes the state of the PE after taking an asynchronous Data Abort exception. Possible values are:

- 00 Uncontainable error (UC) or uncategorized.
- 01 Unrecoverable error (UEU).
- 10 Restartable error (UEO) or Corrected error (CE).
- 11 Recoverable error (UER).

When the RAS Extension is not implemented, or on a synchronous Data Abort, this field is RES0.

Note

ARMv8.2 requires the implementation of the RAS Extension.

In the event of multiple errors taken as a single SError interrupt exception, the overall state of the PE is reported.

Note

Software can use this information to determine what recovery might be possible. The recovery software must also examine any implemented fault records to determine the location and extent of the error.

CM, bit [13]

Cache maintenance fault. For synchronous faults, this bit indicates whether a cache maintenance instruction generated the fault. The possible values of this bit are:

- 0 Abort not caused by execution of a cache maintenance instruction.
- 1 Abort caused by execution of a cache maintenance instruction.

On a synchronous Data Abort on a translation table walk, this bit is UNKNOWN.

On an asynchronous fault, this bit is UNKNOWN.

ExT, bit [12]

External abort type. This bit can be used to provide an IMPLEMENTATION DEFINED classification of external aborts.

In an implementation that does not provide any classification of external aborts, this bit is RES0.

For aborts other than external aborts this bit always returns 0.

WnR, bit [11]

Write not Read bit. Indicates whether the abort was caused by a write or a read instruction. The possible values of this bit are:

- 0 Abort caused by a read instruction.
- 1 Abort caused by a write instruction.

For faults on the cache maintenance and address translation System instructions in the (coproc==1111) encoding space this bit always returns a value of 1.

Bit [10]

Reserved, RES0.

LPAAE, bit [9]

On taking a Data Abort exception, this bit is set as follows:

- 0 Using the Short-descriptor translation table formats.
- 1 Using the Long-descriptor translation table formats.

Hardware does not interpret this bit to determine the behavior of the memory system, and therefore software can set this bit to 0 or 1 without affecting operation.

Bits [8:6]

Reserved, RES0.

STATUS, bits [5:0]

Fault status bits. Possible values of this field are:

- 000000 Address size fault in [TTBR0](#) or [TTBR1](#)
- 000001 Address size fault, level 1
- 000010 Address size fault, level 2
- 000011 Address size fault, level 3
- 000101 Translation fault, level 1
- 000110 Translation fault, level 2
- 000111 Translation fault, level 3
- 001001 Access flag fault, level 1
- 001010 Access flag fault, level 2
- 001011 Access flag fault, level 3
- 001101 Permission fault, level 1
- 001110 Permission fault, level 2
- 001111 Permission fault, level 3
- 010000 Synchronous external abort, not on translation table walk
- 010001 SError interrupt
- 010101 Synchronous external abort, on translation table walk, level 1
- 010110 Synchronous external abort, on translation table walk, level 2
- 010111 Synchronous external abort, on translation table walk, level 3
- 011000 Synchronous parity or ECC error on memory access, not on translation table walk
- 011001 SError interrupt, from a parity or ECC error on memory access
- 011101 Synchronous parity or ECC error on memory access on translation table walk, level 1
- 011110 Synchronous parity or ECC error on memory access on translation table walk, level 2
- 011111 Synchronous parity or ECC error on memory access on translation table walk, level 3
- 100001 Alignment fault
- 100010 Debug exception
- 110000 TLB conflict abort
- 110100 IMPLEMENTATION DEFINED fault (Lockdown fault)
- 110101 IMPLEMENTATION DEFINED fault (Unsupported Exclusive access fault)

All other values are reserved.

When the RAS Extension is implemented, 011000, 011001, 011101, 011110, and 011111 are reserved.

For more information about the lookup level associated with a fault, see *The level associated with MMU faults on a Long-descriptor translation table lookup* on page G4-4671.

Accessing the DFSR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c5, c0, 0	000	000	0101	1111	0000

Accessibility

The register is accessible in software as follows:

Configuration	Control			Accessibility				Instance
	E2H	TGE	NS	EL0	EL1	EL2	EL3	
EL3 is not implemented.	x	x	0	-	RW	n/a	n/a	DFSR
EL3 is not implemented.	x	0	1	-	RW	RW	n/a	DFSR
EL3 is not implemented.	x	1	1	-	n/a	RW	n/a	DFSR
EL3 is using AArch64.	x	x	0	-	RW	n/a	n/a	DFSR
EL3 is using AArch64.	x	0	1	-	RW	RW	n/a	DFSR
EL3 is using AArch64.	x	1	1	-	n/a	RW	n/a	DFSR
EL3 is using AArch32.	x	x	0	-	n/a	n/a	RW	DFSR_s
EL3 is using AArch32.	x	0	1	-	RW	RW	RW	DFSR_ns
EL3 is using AArch32.	x	1	1	-	n/a	RW	RW	DFSR_ns

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If HCR_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
 - If HCR_EL2.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If HSTR_EL2.T5==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If HCR_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.

- If `HCR_EL2.TRVM==1`, Non-secure read accesses to this register from EL1 are trapped to EL2.
- If `HSTR_EL2.T5==1`, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and `SCR_EL3.NS == 1`:
 - If `HCR.TVM==1`, Non-secure write accesses to this register from EL1 are trapped to Hyp mode.
 - If `HCR.TRVM==1`, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
 - If `HSTR.T5==1`, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

G6.2.44 DTLBIALL, Data TLB Invalidate All

The DTLBIALL characteristics are:

Purpose

Invalidate all cached copies of translation table entries from data TLBs that are from any level of the translation table walk. The entries that are invalidated are as follows:

- If executed at Secure EL1 when EL3 is using AArch64, all entries that would be required for the Secure EL1&0 translation regime.
- If executed in Secure state when EL3 is using AArch32, all entries that would be required for the Secure PL1&0 translation regime.
- If executed at Non-secure EL1, all stage 1 translation table entries that would be required for the Non-secure PL1&0 translation regime and, if EL2 is implemented, they must match the current VMID.
- If executed at EL2, the stage 1 or stage 2 translation table entries that would be required for the Non-secure PL1&0 translation regime and matches the current VMID.

The invalidation only applies to the PE that executes this instruction.

ARM deprecates the use of this instruction. It is only provided for backwards compatibility with earlier versions of the ARM architecture.

Configurations

There are no configuration notes.

Attributes

DTLBIALL is a 32-bit System instruction.

Field descriptions

DTLBIALL ignores the value in the register specified by the instruction. Software does not have to write a value to the register before issuing this instruction.

Executing the DTLBIALL instruction

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c8, c6, 0	000	000	1000	1111	0110

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	WO	n/a	WO
x	0	1	-	WO	WO	WO
x	1	1	-	n/a	WO	WO

When `HCR.FB` is 1, at Non-secure EL1 this instruction executes as a `TLBIALLS` operating on data TLBs only.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and `(SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0)`:
 - If `HCR_EL2.TTLB==1`, Non-secure execution of this instruction at EL1 is trapped to EL2.
 - If `HSTR_EL2.T8==1`, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and `(SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0)`:
 - If `HCR_EL2.TTLB==1`, Non-secure execution of this instruction at EL1 is trapped to EL2.
 - If `HSTR_EL2.T8==1`, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and `SCR_EL3.NS == 1`:
 - If `HCR.TTLB==1`, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
 - If `HSTR.T8==1`, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

G6.2.45 DTLBIASID, Data TLB Invalidate by ASID match

The DTLBIASID characteristics are:

Purpose

Invalidate all cached copies of translation table entries from data TLBs that meet the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used for the specified ASID, and either:
 - Is from a level of lookup above the final level.
 - Is a non-global entry from the final level of lookup.
- If EL2 is implemented, the entry would be used with the current VMID.

From the entries that match these requirement, the entries that are invalidated are required for the following translation regime:

- If executed at Secure EL1 when EL3 is using AArch64, the Secure EL1&0 translation regime.
- If executed in Secure state when EL3 is using AArch32, the Secure PL1&0 translation regime.
- If executed in Non-secure state, the Non-secure PL1&0 translation regime.

The invalidation only applies to the PE that executes this instruction.

ARM deprecates the use of this instruction. It is only provided for backwards compatibility with earlier versions of the ARM architecture.

Configurations

There are no configuration notes.

Attributes

DTLBIASID is a 32-bit System instruction.

Field descriptions

The DTLBIASID input value bit assignments are:

Bits [31:8]

Reserved, RES0.

ASID, bits [7:0]

ASID value to match. Any TLB entries for non-global pages that match the ASID values will be affected by this operation.

Executing the DTLBIASID instruction

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c8, c6, 2	000	010	1000	1111	0110

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	WO	n/a	WO
x	0	1	-	WO	WO	WO
x	1	1	-	n/a	WO	WO

When `HCR.FB` is 1, at Non-secure EL1 this instruction executes as a `TLBIASIDIS` operating on data TLBs only.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and `(SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0)`:
 - If `HCR_EL2.TTLB==1`, Non-secure execution of this instruction at EL1 is trapped to EL2.
 - If `HSTR_EL2.T8==1`, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and `(SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0)`:
 - If `HCR_EL2.TTLB==1`, Non-secure execution of this instruction at EL1 is trapped to EL2.
 - If `HSTR_EL2.T8==1`, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and `SCR_EL3.NS == 1`:
 - If `HCR.TTLB==1`, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
 - If `HSTR.T8==1`, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

G6.2.46 DTLBIMVA, Data TLB Invalidate by VA

The DTLBIMVA characteristics are:

Purpose

Invalidate all cached copies of translation table entries from data TLBs that meet the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified address, and one of the following applies:
 - The entry is from a level of lookup above the final level and matches the specified ASID.
 - The entry is a global entry from the final level of lookup.
 - The entry is a non-global entry from the final level of lookup that matches the specified ASID.
- If EL2 is implemented, the entry would be used with the current VMID.

From the entries that match these requirement, the entries that are invalidated are required for the following translation regime:

- If executed at Secure EL1 when EL3 is using AArch64, the Secure EL1&0 translation regime.
- If executed in Secure state when EL3 is using AArch32, the Secure PL1&0 translation regime.
- If executed in Non-secure state, the Non-secure PL1&0 translation regime.

The invalidation only applies to the PE that executes this instruction.

ARM deprecates the use of this instruction. It is only provided for backwards compatibility with earlier versions of the ARM architecture.

Configurations

There are no configuration notes.

Attributes

DTLBIMVA is a 32-bit System instruction.

Field descriptions

The DTLBIMVA input value bit assignments are:

VA, bits [31:12]

Virtual address to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Bits [11:8]

Reserved, RES0.

ASID, bits [7:0]

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Global TLB entries that match the VA value will be affected by this operation, regardless of the value of the ASID field.

Executing the DTLBIMVA instruction

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c8, c6, 1	000	001	1000	1111	0110

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	WO	n/a	WO
x	0	1	-	WO	WO	WO
x	1	1	-	n/a	WO	WO

When [HCR.FB](#) is 1, at Non-secure EL1 this instruction executes as a [TLBIMVAIS](#) operating on data TLBs only.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If [HCR_EL2.TTLB](#)==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
 - If [HSTR_EL2.T8](#)==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If [HCR_EL2.TTLB](#)==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
 - If [HSTR_EL2.T8](#)==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If [HCR.TTLB](#)==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
 - If [HSTR.T8](#)==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

G6.2.47 ELR_hyp, Exception Link Register (Hyp mode)

The ELR_hyp characteristics are:

Purpose

When taking an exception to Hyp mode, holds the address to return to.

Configurations

AArch32 System register ELR_hyp is architecturally mapped to AArch64 System register [ELR_EL2](#).

On a reset into an Exception level that is using AArch32 ELR_hyp is UNKNOWN.

Attributes

ELR_hyp is a 32-bit register.

Field descriptions

The ELR_hyp bit assignments are:

Bits [31:0]

Return address.

Accessing the ELR_hyp

This register can be read using MRS (banked register) with the following syntax:

MRS <Rd>, <banked_reg>

This register can be written using MSR (banked register) with the following syntax:

MSR <banked_reg>, <Rd>

This syntax is encoded with the following settings in the instruction encoding:

<banked_reg>	R	M	M1
ELR_hyp	0	1	1110

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	-
x	0	1	-	-	RW	RW
x	1	1	-	n/a	RW	RW

G6.2.48 FCSEIDR, FCSE Process ID register

The FCSEIDR characteristics are:

Purpose

Identifies whether the Fast Context Switch Extension (FCSE) is implemented.

In ARMv8, the FCSE is not implemented, so this register is RAZ/WI. Software can access this register to determine that the implementation does not include the FCSE.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

Attributes

FCSEIDR is a 32-bit register.

Field descriptions

The FCSEIDR bit assignments are:

Bits [31:0]

Reserved, RAZ/WI. Hardware must implement this as RAZ/WI. Software must not rely on this property as the behavior of reserved values might change in a future revision of the architecture.

Accessing the FCSEIDR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c13, c0, 0	000	000	1101	1111	0000

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	RW	n/a	RW
x	0	1	-	RW	RW	RW
x	1	1	-	n/a	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 0)$:
 - If $HSTR_EL2.T13 == 1$, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 1) \ \&\& \ (HCR_EL2.TGE == 0)$:
 - If $HSTR_EL2.T13 == 1$, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $HSTR.T13 == 1$, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

G6.2.49 FPEXC, Floating-Point Exception Control register

The FPEXC characteristics are:

Purpose

Provides a global enable for the implemented Advanced SIMD and floating-point functionality, and reports floating-point status information.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register FPEXC is architecturally mapped to AArch64 System register [FPEXC32_EL2](#).

Implemented only if the implementation includes the Advanced SIMD and floating-point functionality.

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into an Exception level that is using AArch32. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

Attributes

FPEXC is a 32-bit register.

Field descriptions

The FPEXC bit assignments are:

EX, bit [31]

Exception bit. In ARMv8, this bit is RAZ/WI.

EN, bit [30]

Enables access to the Advanced SIMD and floating-point functionality from all Exception levels, except that setting this field to 0 does not disable the following:

- VMRS accesses to the [FPEXC](#) or [FPSID](#).
- VMRS accesses from the [FPEXC](#), [FPSID](#), [MVFR0](#), [MVFR1](#), or [MVFR2](#).

0 Accesses to the [FPSCR](#), and any of the SIMD and floating-point registers Q0-Q15, including their views as D0-D31 registers or S0-S31 registers, are UNDEFINED at all Exception levels.

1 This control permits access to the Advanced SIMD and floating-point functionality at all Exception levels.

Execution of floating-point and Advanced SIMD instructions in AArch32 state can be disabled or trapped by the following controls:

- [CPACR.cp10](#), or, if executing at EL0, [CPACR_EL1.FPEN](#).

- FPEXC.EN.
- If executing in Non-secure state:
 - `HCPTTR.TCP10`, or if EL2 is using AArch64, `CPTR_EL2.TFP`.
 - `NSACR.cp10`, or if EL3 is using AArch64, `CPTR_EL3.TFP`.
- For Advanced SIMD instructions only:
 - `CPACR.ASEDIS`.
 - If executing in Non-secure state, `HCPTTR.TASE` and `NSACR.NSTRCDIS`.

See the descriptions of the controls for more information.

———— **Note** —————

When executing at EL0 using AArch32:

- If EL1 is using AArch64 then behavior is as if the value of FPEXC.EN is 1.
- In Non-secure state, if EL2 is using AArch64 and the value of `HCR_EL2`.{RW, TGE} is {1, 1} then behavior is as if the value of FPEXC.EN is 1.
- In Non-secure state, if EL2 is using AArch64 and the value of `HCR_EL2`.{RW, TGE} is {0, 1} then it is IMPLEMENTATION DEFINED whether the behavior is:
 - As if the value of FPEXC.EN is 1.
 - Determined by the value of FPEXC.EN, as described in this field description.
ARM deprecates using the value of FPEXC.EN to determine behavior.

When this register has an architecturally-defined reset value, this field resets to 0.

DEX, bit [29]

Defined synchronous exception on floating-point execution.

This field identifies whether a synchronous exception generated by the attempted execution of an instruction was generated by an unallocated encoding. The instruction must be in the encoding space that is identified by the pseudocode function `ExecutingCP10or11Instr()` returning TRUE. This field also indicates whether the FPEXC.TFV field is valid.

The meaning of this bit is:

- | | |
|---|---|
| 0 | The exception was generated by the attempted execution of an unallocated instruction in the encoding space that is identified by the pseudocode function <code>ExecutingCP10or11Instr()</code> . If FPEXC.TFV is RW then it is invalid and UNKNOWN. If FPEXC.{IDF, IXF, UFF, OFF, DZF, IOF} are RW then they are invalid and UNKNOWN. |
| 1 | The exception was generated during the execution of an unallocated encoding. FPEXC.TFV is valid and indicates the cause of the exception. |

On an exception that sets this bit to 1 the exception-handling routine must clear this bit to 0.

On an implementation that both does not support trapping of floating-point exceptions and implements the `FPSCR`.{Stride, Len} fields as RAZ, this bit is RES0.

If this field is implemented as an RW field, it resets to a value that is architecturally UNKNOWN.

FP2V, bit [28]

FPINST2 instruction valid bit. In ARMv8, this bit is RES0.

VV, bit [27]

VECITR valid bit. In ARMv8, this bit is RES0.

TFV, bit [26]

Trapped Fault Valid bit. Valid only when the value of FPEXC.DEX is 1. When valid, it indicates the cause of the exception and therefore whether the FPEXC.{IDF, IXF, UFF, OFF, DZF, IOF} bits are valid.

- 0 The exception was caused by the execution of a floating-point VABS, VADD, VDIV, VFMA, VFMS, VFNMA, VFNMS, VMLA, VMLS, VMOV, VMUL, VNEG, VNMLA, VNMLS, VNMUL, VSQRT, or VSUB instruction when one or both of FPSCR.{Stride, Len} was non-zero. If the FPEXC.{IDF, IXF, UFF, OFF, DZF, IOF} bits are RW then they are invalid and UNKNOWN.
- 1 FPEXC.{IDF, IXF, UFF, OFF, DZF, IOF} indicate the presence of trapped floating-point exceptions that had occurred at the time of the exception. Bits are set for all trapped exceptions that had occurred at the time of the exception.

This bit returns a status value and ignores writes.

When the value of FPEXC.DEX is 0 and this bit is RW, this bit is invalid and UNKNOWN.

On an implementation that does not support the trapping of floating-point exceptions this bit is RAZ/WI.

On an implementation that supports the trapping of floating-point exceptions and implements FPSCR.{Stride, Len} as RAZ, this bit is RAO/WI.

Bits [25:11]

Reserved, RES0.

VECITR, bits [10:8]

Vector iteration count. In ARMv8, this field is RES1.

IDF, bit [7]

Input Denormal trapped exception bit. Valid only when the value of FPEXC.TFV is 1. When valid, it indicates whether an Input Denormal exception occurred while FPSCR.IDE was 1:

- 0 Input denormal exception has not occurred.
- 1 Input denormal exception has occurred.

Input Denormal exceptions can occur only when FPSCR.FZ is 1.

This bit must be cleared to 0 by the exception-handling routine.

When the value of FPEXC.TFV is 0 and this bit is RW, this bit is invalid and UNKNOWN.

On an implementation that does not support the trapping of floating-point exceptions this bit is RAZ/WI.

If this field is implemented as an RW field, it resets to a value that is architecturally UNKNOWN.

Bits [6:5]

Reserved, RES0.

IXF, bit [4]

Inexact trapped exception bit. Valid only when the value of FPEXC.TFV is 1. When valid, it indicates whether an Inexact exception occurred while FPSCR.IXE was 1:

- 0 Inexact exception has not occurred.
- 1 Inexact exception has occurred.

This bit must be cleared to 0 by the exception-handling routine.

When the value of FPEXC.TFV is 0 and this bit is RW, this bit is invalid and UNKNOWN.

On an implementation that does not support the trapping of floating-point exceptions this bit is RAZ/WI.

If this field is implemented as an RW field, it resets to a value that is architecturally UNKNOWN.

UFF, bit [3]

Underflow trapped exception bit. Valid only when the value of FPEXC.TFV is 1. When valid, it indicates whether an Underflow exception occurred while FPSCR.UFE was 1:

- 0 Underflow exception has not occurred.
- 1 Underflow exception has occurred.

Underflow trapped exceptions can occur only when FPSCR.FZ is 0.

This bit must be cleared to 0 by the exception-handling routine.

When the value of FPEXC.TFV is 0 and this bit is RW, this bit is invalid and UNKNOWN.

On an implementation that does not support the trapping of floating-point exceptions this bit is RAZ/WI.

If this field is implemented as an RW field, it resets to a value that is architecturally UNKNOWN.

OFF, bit [2]

Overflow trapped exception bit. Valid only when the value of FPEXC.TFV is 1. When valid, it indicates whether an Overflow exception occurred while FPSCR.OFE was 1:

- 0 Overflow exception has not occurred.
- 1 Overflow exception has occurred.

This bit must be cleared to 0 by the exception-handling routine.

When the value of FPEXC.TFV is 0 and this bit is RW, this bit is invalid and UNKNOWN.

On an implementation that does not support the trapping of floating-point exceptions this bit is RAZ/WI.

If this field is implemented as an RW field, it resets to a value that is architecturally UNKNOWN.

DZF, bit [1]

Divide by Zero trapped exception bit. Valid only when the value of FPEXC.TFV is 1. When valid, it indicates whether a Divide by Zero exception occurred while FPSCR.DZE was 1:

- 0 Divide by Zero exception has not occurred.
- 1 Divide by Zero exception has occurred.

This bit must be cleared to 0 by the exception-handling routine.

When the value of FPEXC.TFV is 0 and this bit is RW, this bit is invalid and UNKNOWN.

On an implementation that does not support the trapping of floating-point exceptions this bit is RAZ/WI.

If this field is implemented as an RW field, it resets to a value that is architecturally UNKNOWN.

IOF, bit [0]

Invalid Operation trapped exception bit. Valid only when the value of FPEXC.TFV is 1. When valid, it indicates whether an Invalid Operation exception occurred while FPSCR.IOE was 1:

- 0 Invalid Operation exception has not occurred.
- 1 Invalid Operation exception has occurred.

This bit must be cleared to 0 by the exception-handling routine.

When the value of FPEXC.TFV is 0 and this bit is RW, this bit is invalid and UNKNOWN.

On an implementation that does not support the trapping of floating-point exceptions this bit is RAZ/WI.

If this field is implemented as an RW field, it resets to a value that is architecturally UNKNOWN.

Accessing the FPEXC

This register can be read using VMRS with the following syntax:

```
VMRS <Rt>, <spec_reg>
```

This register can be written using VMSR with the following syntax:

VMSR <spec_reg>, <Rt>

This syntax is encoded with the following settings in the instruction encoding:

<spec_reg>	reg
FPEXC	1000

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	RW	n/a	RW
x	0	1	-	RW	RW	RW
x	1	1	-	n/a	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When $HCR_EL2.E2H == 0$:
 - If $CPACR.cp10 == 00$, accesses to this register from PL1 are UNDEFINED.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \&\& (HCR_EL2.E2H == 0)$:
 - If $CPTR_EL2.TFP == 1$, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \&\& (HCR_EL2.E2H == 1) \&\& (HCR_EL2.TGE == 0)$:
 - If $CPTR_EL2.FPEN == 00$, Non-secure accesses to this register from EL1 are trapped to EL2.
 - If $CPTR_EL2.FPEN == 10$, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $HCPTR.TCP10 == 1$, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
 - If $HCPTR.TCP10 == 1$, Non-secure accesses to this register from EL2 are UNDEFINED.
- When EL3 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $NSACR.cp10 == 0$, Non-secure accesses to this register from EL1 and EL2 are UNDEFINED.
- When EL3 is implemented and is using AArch64:
 - If $CPTR_EL3.TFP == 1$, accesses to this register from EL1 and EL2 are trapped to EL3.

G6.2.50 FPSCR, Floating-Point Status and Control Register

The FPSCR characteristics are:

Purpose

Provides floating-point system status information and control.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

The named fields in this register map to the equivalent fields in the AArch64 [FPCR](#) and [FPSR](#).

It is IMPLEMENTATION DEFINED whether the Len and Stride fields can be programmed to non-zero values, which will cause some AArch32 floating-point instruction encodings to be UNDEFINED, or whether these fields are RAZ.

Implemented only if the implementation includes the Advanced SIMD and floating-point functionality.

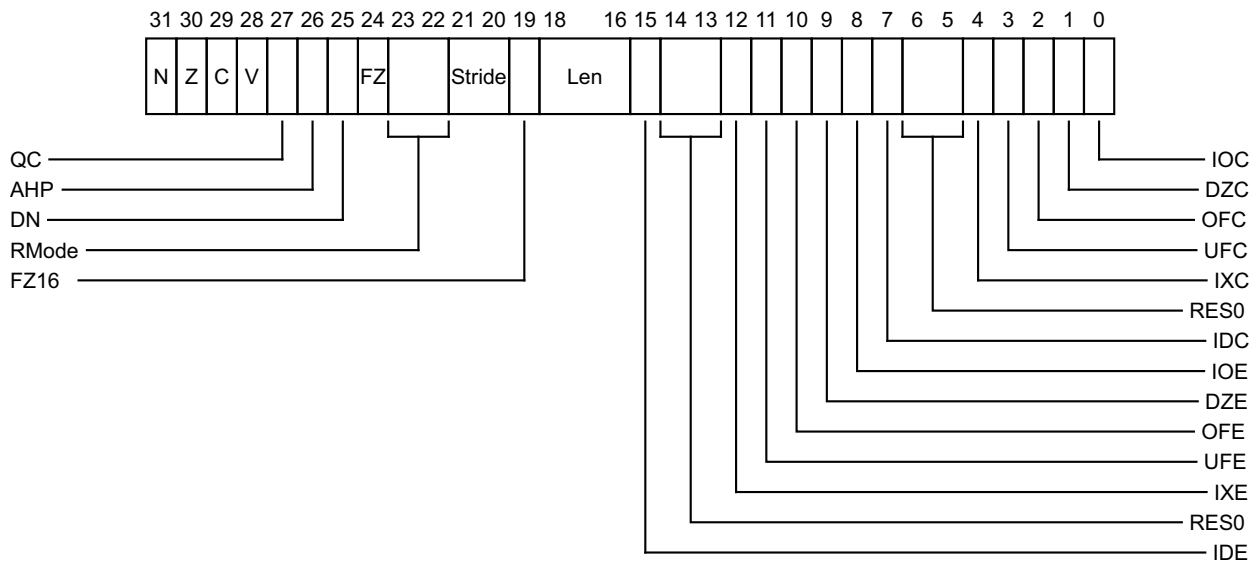

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

FPSCR is a 32-bit register.

Field descriptions

The FPSCR bit assignments are:

N, bit [31]

Negative condition flag. This is updated by floating-point comparison operations.

Z, bit [30]

Zero condition flag. This is updated by floating-point comparison operations.

C, bit [29]

Carry condition flag. This is updated by floating-point comparison operations.

V, bit [28]

Overflow condition flag. This is updated by floating-point comparison operations.

QC, bit [27]

Cumulative saturation bit, Advanced SIMD only. This bit is set to 1 to indicate that an Advanced SIMD integer operation has saturated since 0 was last written to this bit.

AHP, bit [26]

Alternative half-precision control bit:

- 0 IEEE half-precision format selected.
- 1 Alternative half-precision format selected.

This bit is only used for conversions between half-precision floating-point and other floating-point formats.

The data-processing instructions added as part of the [ARMv8.2-FP16](#) extension always use the IEEE half-precision format, and ignore the value of this bit.

DN, bit [25]

Default NaN mode control bit:

- 0 NaN operands propagate through to the output of a floating-point operation.
- 1 Any operation involving one or more NaNs returns the Default NaN.

The value of this bit only controls scalar floating-point arithmetic. Advanced SIMD arithmetic always uses the Default NaN setting, regardless of the value of the DN bit.

FZ, bit [24]

Flush-to-zero mode control bit:

- 0 Flush-to-zero mode disabled. Behavior of the floating-point system is fully compliant with the IEEE 754 standard.
- 1 Flush-to-zero mode enabled.

The value of this bit only controls scalar floating-point arithmetic. Advanced SIMD arithmetic always uses the Flush-to-zero setting, regardless of the value of the FZ bit.

This bit has no effect on half-precision calculations.

RMode, bits [23:22]

Rounding Mode control field. The encoding of this field is:

- 00 Round to Nearest (RN) mode
- 01 Round towards Plus Infinity (RP) mode
- 10 Round towards Minus Infinity (RM) mode
- 11 Round towards Zero (RZ) mode.

The specified rounding mode is used by almost all scalar floating-point instructions. Advanced SIMD arithmetic always uses the Round to Nearest setting, regardless of the value of the RMode bits.

Stride, bits [21:20]

It is IMPLEMENTATION DEFINED whether this field is RW or RAZ.

If this field is RW and is set to a value other than zero, some floating-point instruction encodings are UNDEFINED. The instruction pseudocode identifies these instructions.

ARM strongly recommends that software never sets this field to a value other than zero.

The value of this field is ignored when processing Advanced SIMD instructions.

FZ16, bit [19]

In ARMv8.2

When [ARMv8.2-FP16](#) is implemented, flush-to-zero mode control bit on half-precision data-processing instructions:

- 0 Flush-to-zero mode disabled. Behavior of the floating-point system is fully compliant with the IEEE 754 standard.
- 1 Flush-to-zero mode enabled.

The value of this bit applies to both scalar and Advanced SIMD floating-point half-precision calculations.

When [ARMv8.2-FP16](#) is not implemented, this bit is RES0.

In ARMv8.1 and ARMv8.0.

Reserved, RES0.

Len, bits [18:16]

It is IMPLEMENTATION DEFINED whether this field is RW or RAZ.

If this field is RW and is set to a value other than zero, some floating-point instruction encodings are UNDEFINED. The instruction pseudocode identifies these instructions.

ARM strongly recommends that software never sets this field to a value other than zero.

The value of this field is ignored when processing Advanced SIMD instructions.

IDE, bit [15]

Input Denormal floating-point exception trap enable. Possible values are:

- 0 Untrapped exception handling selected. If the floating-point exception occurs then the IDC bit is set to 1.
- 1 Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the IDC bit. The trap handling software can decide whether to set the IDC bit to 1.

This bit is RW only if the implementation supports the trapping of floating-point exceptions. In an implementation that does not support floating-point exception trapping, this bit is RES0.

When this bit is RW, it applies only to floating-point operations. Advanced SIMD operations always use untrapped floating-point exception handling in AArch32 state.

Bits [14:13]

Reserved, RES0.

IXE, bit [12]

Inexact floating-point exception trap enable. Possible values are:

- 0 Untrapped exception handling selected. If the floating-point exception occurs then the IXC bit is set to 1.
- 1 Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the IXC bit. The trap handling software can decide whether to set the IXC bit to 1.

This bit is RW only if the implementation supports the trapping of floating-point exceptions. In an implementation that does not support floating-point exception trapping, this bit is RES0.

When this bit is RW, it applies only to floating-point operations. Advanced SIMD operations always use untrapped floating-point exception handling in AArch32 state.

UFE, bit [11]

Underflow floating-point exception trap enable. Possible values are:

- 0 Untrapped exception handling selected. If the floating-point exception occurs then the UFC bit is set to 1.
- 1 Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the UFC bit. The trap handling software can decide whether to set the UFC bit to 1.

This bit is RW only if the implementation supports the trapping of floating-point exceptions. In an implementation that does not support floating-point exception trapping, this bit is RES0.

When this bit is RW, it applies only to floating-point operations. Advanced SIMD operations always use untrapped floating-point exception handling in AArch32 state.

OFE, bit [10]

Overflow floating-point exception trap enable. Possible values are:

- 0 Untrapped exception handling selected. If the floating-point exception occurs then the OFC bit is set to 1.
- 1 Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the OFC bit. The trap handling software can decide whether to set the OFC bit to 1.

This bit is RW only if the implementation supports the trapping of floating-point exceptions. In an implementation that does not support floating-point exception trapping, this bit is RES0.

When this bit is RW, it applies only to floating-point operations. Advanced SIMD operations always use untrapped floating-point exception handling in AArch32 state.

DZE, bit [9]

Divide by Zero floating-point exception trap enable. Possible values are:

- 0 Untrapped exception handling selected. If the floating-point exception occurs then the DZC bit is set to 1.
- 1 Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the DZC bit. The trap handling software can decide whether to set the DZC bit to 1.

This bit is RW only if the implementation supports the trapping of floating-point exceptions. In an implementation that does not support floating-point exception trapping, this bit is RES0.

When this bit is RW, it applies only to floating-point operations. Advanced SIMD operations always use untrapped floating-point exception handling in AArch32 state.

IOE, bit [8]

Invalid Operation floating-point exception trap enable. Possible values are:

- 0 Untrapped exception handling selected. If the floating-point exception occurs then the IOC bit is set to 1.
- 1 Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the IOC bit. The trap handling software can decide whether to set the IOC bit to 1.

This bit is RW only if the implementation supports the trapping of floating-point exceptions. In an implementation that does not support floating-point exception trapping, this bit is RES0.

When this bit is RW, it applies only to floating-point operations. Advanced SIMD operations always use untrapped floating-point exception handling in AArch32 state.

IDC, bit [7]

Input Denormal cumulative floating-point exception bit. This bit is set to 1 to indicate that the Input Denormal floating-point exception has occurred since 0 was last written to this bit.

How VFP instructions update this bit depends on the value of the IDE bit.

Advanced SIMD instructions set this bit if the Input Denormal floating-point exception occurs in one or more of the floating-point calculations performed by the instruction, regardless of the value of the IDE bit.

Bits [6:5]

Reserved, RES0.

IXC, bit [4]

Inexact cumulative floating-point exception bit. This bit is set to 1 to indicate that the Inexact floating-point exception has occurred since 0 was last written to this bit.

How VFP instructions update this bit depends on the value of the IXE bit.

Advanced SIMD instructions set this bit if the Inexact floating-point exception occurs in one or more of the floating-point calculations performed by the instruction, regardless of the value of the IXE bit.

UFC, bit [3]

Underflow cumulative floating-point exception bit. This bit is set to 1 to indicate that the Underflow floating-point exception has occurred since 0 was last written to this bit.

How VFP instructions update this bit depends on the value of the UFE bit.

Advanced SIMD instructions set this bit if the Underflow floating-point exception occurs in one or more of the floating-point calculations performed by the instruction, regardless of the value of the UFE bit.

OFC, bit [2]

Overflow cumulative floating-point exception bit. This bit is set to 1 to indicate that the Overflow floating-point exception has occurred since 0 was last written to this bit.

How VFP instructions update this bit depends on the value of the OFE bit.

Advanced SIMD instructions set this bit if the Overflow floating-point exception occurs in one or more of the floating-point calculations performed by the instruction, regardless of the value of the OFE bit.

DZC, bit [1]

Divide by Zero cumulative floating-point exception bit. This bit is set to 1 to indicate that the Divide by Zero floating-point exception has occurred since 0 was last written to this bit.

How VFP instructions update this bit depends on the value of the DZE bit.

Advanced SIMD instructions set this bit if the Divide by Zero floating-point exception occurs in one or more of the floating-point calculations performed by the instruction, regardless of the value of the DZE bit.

IOC, bit [0]

Invalid Operation cumulative floating-point exception bit. This bit is set to 1 to indicate that the Invalid Operation floating-point exception has occurred since 0 was last written to this bit.

How VFP instructions update this bit depends on the value of the IOE bit.

Advanced SIMD instructions set this bit if the Invalid Operation floating-point exception occurs in one or more of the floating-point calculations performed by the instruction, regardless of the value of the IOE bit.

Accessing the FPSCR

This register can be read using VMRS with the following syntax:

```
VMRS <Rt>, <spec_reg>
```

This register can be written using VMSR with the following syntax:

```
VMSR <spec_reg>, <Rt>
```

This syntax is encoded with the following settings in the instruction encoding:

<spec_reg>	reg
FPSCR	0001

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	RW	RW	n/a	RW
x	0	1	RW	RW	RW	RW
x	1	1	RW	n/a	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When $HCR_EL2.E2H == 0$:
 - If $CPACR.cp10 == 00$, accesses to this register from PL0 and PL1 are UNDEFINED.
 - If $CPACR.cp10 == 01$, accesses to this register from PL0 are UNDEFINED.
 - If $CPACR_EL1.FPEN == 00$, accesses to this register from PL0 are trapped to EL1.
 - If $CPACR_EL1.FPEN == 01$, accesses to this register from PL0 are trapped to EL1.
 - If $CPACR_EL1.FPEN == 10$, accesses to this register from PL0 are trapped to EL1.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \&\& (HCR_EL2.E2H == 0)$:
 - If $CPTR_EL2.TFP == 1$, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \&\& (HCR_EL2.E2H == 1) \&\& (HCR_EL2.TGE == 0)$:
 - If $CPACR_EL1.FPEN == 00$, Non-secure accesses to this register from EL0 are trapped to EL1.
 - If $CPACR_EL1.FPEN == 01$, Non-secure accesses to this register from EL0 are trapped to EL1.
 - If $CPACR_EL1.FPEN == 10$, Non-secure accesses to this register from EL0 are trapped to EL1.
 - If $CPTR_EL2.FPEN == 00$, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.
 - If $CPTR_EL2.FPEN == 10$, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \&\& (HCR_EL2.E2H == 1) \&\& (HCR_EL2.TGE == 1)$:
 - If $CPTR_EL2.FPEN == 00$, Non-secure accesses to this register from EL0 are trapped to EL2.
 - If $CPTR_EL2.FPEN == 01$, Non-secure accesses to this register from EL0 are trapped to EL2.
 - If $CPTR_EL2.FPEN == 10$, Non-secure accesses to this register from EL0 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $HCPTR.TCP10 == 1$, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.
 - If $HCPTR.TCP10 == 1$, Non-secure accesses to this register from EL2 are UNDEFINED.
- When EL3 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $NSACR.cp10 == 0$, Non-secure accesses to this register from EL0, EL1, and EL2 are UNDEFINED.

- When EL3 is implemented and is using AArch64:
 - If [CPTR_EL3.TFP](#)==1, accesses to this register from EL0, EL1, and EL2 are trapped to EL3.

G6.2.51 FPSID, Floating-Point System ID register

The FPSID characteristics are:

Purpose

Provides top-level information about the floating-point implementation.

This register largely duplicates information held in the [MIDR](#). ARM deprecates use of it.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

Implemented only if the implementation includes the Advanced SIMD and floating-point functionality.

Attributes

FPSID is a 32-bit register.

Field descriptions

The FPSID bit assignments are:

Implementer, bits [31:24]

Implementer codes are the same as those used for the [MIDR](#).

For an implementation by ARM this field is 0x41, the ASCII code for A.

SW, bit [23]

Software bit. Defined values are:

0 The implementation provides a hardware implementation of the floating-point instructions.

1 The implementation supports only software emulation of the floating-point instructions.

In ARMv8-A the only permitted value is 0.

Subarchitecture, bits [22:16]

Subarchitecture version number. For an implementation by ARM, defined values are:

0000000 VFPv1 architecture with an IMPLEMENTATION DEFINED subarchitecture.

0000001 VFPv2 architecture with Common VFP subarchitecture v1.

0000010 VFPv3 architecture, or later, with Common VFP subarchitecture v2. The VFP architecture version is indicated by the [MVFR0](#) and [MVFR1](#) registers.

0000011 VFPv3 architecture, or later, with Null subarchitecture. The entire floating-point implementation is in hardware, and no software support code is required. The VFP architecture version is indicated by the [MVFR0](#) and [MVFR1](#) registers. This value can be used only by an implementation that does not support the trap enable bits in the [FPSCR](#).

0000100 VFPv3 architecture, or later, with Common VFP subarchitecture v3, and support for trap enable bits in [FPSCR](#). The VFP architecture version is indicated by the [MVFR0](#) and [MVFR1](#) registers.

For a subarchitecture designed by ARM the most significant bit of this field, register bit[22], is 0. Values with a most significant bit of 0 that are not listed here are reserved.

When the subarchitecture designer is not ARM, the most significant bit of this field, register bit[22], must be 1. Each implementer must maintain its own list of subarchitectures it has designed, starting at subarchitecture version number 0x40.

In ARMv8-A the permitted values are 0000011 and 0000100.

PartNum, bits [15:8]

An IMPLEMENTATION DEFINED part number for the floating-point implementation, assigned by the implementer.

Variant, bits [7:4]

An IMPLEMENTATION DEFINED variant number. Typically, this field distinguishes between different production variants of a single product.

Revision, bits [3:0]

An IMPLEMENTATION DEFINED revision number for the floating-point implementation.

Accessing the FPSID

This register can be read using VMRS with the following syntax:

```
VMRS <Rt>, <spec_reg>
```

This register can be written using VMSR with the following syntax:

```
VMSR <spec_reg>, <Rt>
```

This syntax is encoded with the following settings in the instruction encoding:

<spec_reg>	reg
FPSID	0000

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	RW	n/a	RW
x	0	1	-	RW	RW	RW
x	1	1	-	n/a	RW	RW

When access to this register is permitted, write accesses are ignored.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When $\text{HCR_EL2.E2H} == 0$:
 - If $\text{CPACR.cp10} == 0$, accesses to this register from PL1 are UNDEFINED.
- When EL2 is implemented and is using AArch64 and $(\text{SCR_EL3.NS} == 1) \ \&\& \ (\text{HCR_EL2.E2H} == 0)$:
 - If $\text{CPTR_EL2.TFP} == 1$, Non-secure accesses to this register from EL1 are trapped to EL2.
 - If $\text{HCR_EL2.TID0} == 1$, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(\text{SCR_EL3.NS} == 1) \ \&\& \ (\text{HCR_EL2.E2H} == 1) \ \&\& \ (\text{HCR_EL2.TGE} == 0)$:
 - If $\text{CPTR_EL2.FPEN} == 0$, Non-secure accesses to this register from EL1 are trapped to EL2.
 - If $\text{CPTR_EL2.FPEN} == 1$, Non-secure accesses to this register from EL1 are trapped to EL2.
 - If $\text{HCR_EL2.TID0} == 1$, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and $\text{SCR_EL3.NS} == 1$:
 - If $\text{HCPTR.TCP10} == 1$, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
 - If $\text{HCPTR.TCP10} == 0$, Non-secure accesses to this register from EL2 are UNDEFINED.
 - If $\text{HCR.TID0} == 1$, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
- When EL3 is implemented and is using AArch32 and $\text{SCR_EL3.NS} == 1$:
 - If $\text{NSACR.cp10} == 0$, Non-secure accesses to this register from EL1 and EL2 are UNDEFINED.
- When EL3 is implemented and is using AArch64:
 - If $\text{CPTR_EL3.TFP} == 1$, accesses to this register from EL1 and EL2 are trapped to EL3.

G6.2.52 HACR, Hyp Auxiliary Configuration Register

The HACR characteristics are:

Purpose

Controls trapping to Hyp mode of IMPLEMENTATION DEFINED aspects of Non-secure EL1 or EL0 operation.

Configurations

AArch32 System register HACR is architecturally mapped to AArch64 System register [HACR_EL2](#).

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

HACR is a 32-bit register.

Field descriptions

The HACR bit assignments are:

IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

Accessing the HACR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 4, <Rt>, c1, c1, 7	100	111	0001	1111	0001

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	-
x	0	1	-	-	RW	RW
x	1	1	-	n/a	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 0)$:
 - If $HSTR_EL2.T1 == 1$, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 1) \ \&\& \ (HCR_EL2.TGE == 0)$:
 - If $HSTR_EL2.T1 == 1$, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $HSTR.T1 == 1$, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

G6.2.53 HACTLR, Hyp Auxiliary Control Register

The HACTLR characteristics are:

Purpose

Controls IMPLEMENTATION DEFINED features of Hyp mode operation.

Configurations

AArch32 System register HACTLR is architecturally mapped to AArch64 System register [ACTLR_EL2](#)[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

HACTLR is a 32-bit register.

Field descriptions

The HACTLR bit assignments are:

IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

Accessing the HACTLR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 4, <Rt>, c1, c0, 1	100	001	0001	1111	0000

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	-
x	0	1	-	-	RW	RW
x	1	1	-	n/a	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 0)$:
 - If $HSTR_EL2.T1 == 1$, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 1) \ \&\& \ (HCR_EL2.TGE == 0)$:
 - If $HSTR_EL2.T1 == 1$, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $HSTR.T1 == 1$, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

G6.2.54 HACTLR2, Hyp Auxiliary Control Register 2

The HACTLR2 characteristics are:

Purpose

Provides additional space to the HACTLR register to hold IMPLEMENTATION DEFINED trap functionality.

Configurations

AArch32 System register HACTLR2 is architecturally mapped to AArch64 System register [ACTLR_EL2](#)[63:32].

In ARMv8.0 and ARMv8.1, it is IMPLEMENTATION DEFINED whether this register is implemented, or whether it causes UNDEFINED exceptions when accessed. The implementation of this register can be detected by examining [ID_MMFR4.AC2](#).

From ARMv8.2 this register must be implemented.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

HACTLR2 is a 32-bit register.

Field descriptions

The HACTLR2 bit assignments are:

IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

Accessing the HACTLR2

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 4, <Rt>, c1, c0, 3	100	011	0001	1111	0000

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	-
x	0	1	-	-	RW	RW
x	1	1	-	n/a	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If [HSTR_EL2.T1](#)==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If [HSTR_EL2.T1](#)==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If [HSTR.T1](#)==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

G6.2.55 HADFSR, Hyp Auxiliary Data Fault Status Register

The HADFSR characteristics are:

Purpose

Provides additional IMPLEMENTATION DEFINED syndrome information for Data Abort exceptions taken to Hyp mode.

Configurations

AArch32 System register HADFSR is architecturally mapped to AArch64 System register [AFSR0_EL2](#).

This is an optional register. An implementation that does not require this register can implement it as RES0.

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

HADFSR is a 32-bit register.

Field descriptions

The HADFSR bit assignments are:

IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

Accessing the HADFSR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 4, <Rt>, c5, c1, 0	100	000	0101	1111	0001

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	-
x	0	1	-	-	RW	RW
x	1	1	-	n/a	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If [HSTR_EL2.T5](#)==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If [HSTR_EL2.T5](#)==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If [HSTR.T5](#)==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

G6.2.56 HAIFSR, Hyp Auxiliary Instruction Fault Status Register

The HAIFSR characteristics are:

Purpose

Provides additional IMPLEMENTATION DEFINED syndrome information for Prefetch Abort exceptions taken to Hyp mode.

Configurations

AArch32 System register HAIFSR is architecturally mapped to AArch64 System register [AFSR1_EL2](#).

This is an optional register. An implementation that does not require this register can implement it as RES0.

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

HAIFSR is a 32-bit register.

Field descriptions

The HAIFSR bit assignments are:

IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

Accessing the HAIFSR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 4, <Rt>, c5, c1, 1	100	001	0101	1111	0001

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	-
x	0	1	-	-	RW	RW
x	1	1	-	n/a	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If [HSTR_EL2.T5](#)==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If [HSTR_EL2.T5](#)==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If [HSTR.T5](#)==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

G6.2.57 HMAIR0, Hyp Auxiliary Memory Attribute Indirection Register 0

The HMAIR0 characteristics are:

Purpose

Provides IMPLEMENTATION DEFINED memory attributes for the memory attribute encodings defined by [HMAIR0](#). These IMPLEMENTATION DEFINED attributes can only provide additional qualifiers for the memory attribute encodings, and cannot change the memory attributes defined in [HMAIR0](#).

Configurations

AArch32 System register HMAIR0 is architecturally mapped to AArch64 System register [AMAIR_EL2](#)[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

HMAIR0 is a 32-bit register.

Field descriptions

The HMAIR0 bit assignments are:

If an implementation does not provide any IMPLEMENTATION DEFINED memory attributes, this register is RES0.

IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

Accessing the HMAIR0

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 4, <Rt>, c10, c3, 0	100	000	1010	1111	0011

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	-
x	0	1	-	-	RW	RW
x	1	1	-	n/a	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 0)$:
 - If $HSTR_EL2.T10 == 1$, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 1) \ \&\& \ (HCR_EL2.TGE == 0)$:
 - If $HSTR_EL2.T10 == 1$, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $HSTR.T10 == 1$, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

G6.2.58 HMAIR1, Hyp Auxiliary Memory Attribute Indirection Register 1

The HMAIR1 characteristics are:

Purpose

Provides IMPLEMENTATION DEFINED memory attributes for the memory attribute encodings defined by [HMAIR1](#). These IMPLEMENTATION DEFINED attributes can only provide additional qualifiers for the memory attribute encodings, and cannot change the memory attributes defined in [HMAIR1](#).

Configurations

AArch32 System register HMAIR1 is architecturally mapped to AArch64 System register [AMAIR_EL2](#)[63:32].

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

HMAIR1 is a 32-bit register.

Field descriptions

The HMAIR1 bit assignments are:

If an implementation does not provide any IMPLEMENTATION DEFINED memory attributes, this register is RES0.

IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

Accessing the HMAIR1

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 4, <Rt>, c10, c3, 1	100	001	1010	1111	0011

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	-
x	0	1	-	-	RW	RW
x	1	1	-	n/a	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If [HSTR_EL2.T10==1](#), Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If [HSTR_EL2.T10==1](#), Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If [HSTR.T10==1](#), Non-secure accesses to this register from EL1 are trapped to Hyp mode.

G6.2.59 HCPTR, Hyp Architectural Feature Trap Register

The HCPTR characteristics are:

Purpose

Controls:

- Trapping to Hyp mode of Non-secure access, at EL1 or EL0, to trace, and to Advanced SIMD and floating-point functionality.
- Hyp mode access to trace, and to Advanced SIMD and floating-point functionality.

———— Note ————

Accesses to this functionality:

- From Non-secure modes other than Hyp mode are also affected by settings in the [CPACR](#) and [NSACR](#).
- From Hyp mode are also affected by settings in the [NSACR](#).

Exceptions generated by the [CPACR](#) and [NSACR](#) controls are higher priority than those generated by the HCPTR controls.

Configurations

AArch32 System register HCPTR is architecturally mapped to AArch64 System register [CPTR_EL2](#).

If EL2 is not implemented, this register is RES0 from EL3.

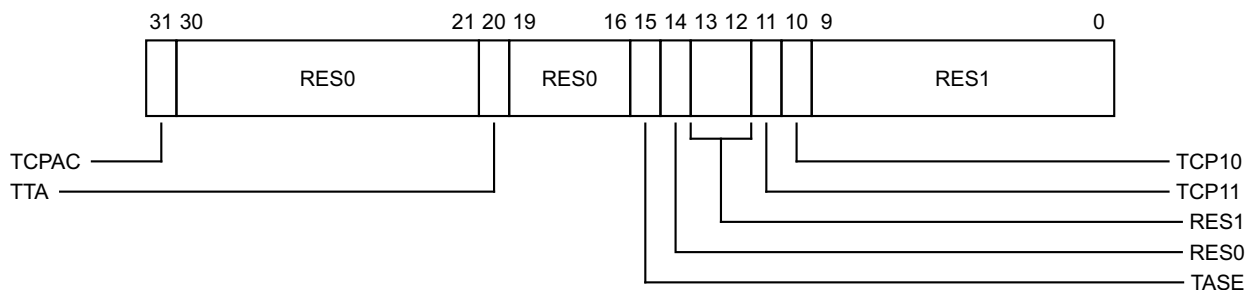

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into EL2 with EL2 using AArch32, or into EL3 with EL3 using AArch32. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

Attributes

HCPTR is a 32-bit register.

Field descriptions

The HCPTR bit assignments are:

TCPAC, bit [31]

Traps Non-secure EL1 accesses to the [CPACR](#) to Hyp mode.

0 This control does not cause any instructions to be trapped.

1 Non-secure EL1 accesses to the [CPACR](#) are trapped to Hyp mode.

———— Note ————

The [CPACR](#) is not accessible at EL0.

When this register has an architecturally-defined reset value, this field resets to 0.

Bits [30:21]

Reserved, RES0.

TTA, bit [20]

Traps Non-secure System register accesses to all implemented trace registers to Hyp mode.

- 0 This control does not cause any instructions to be trapped.
- 1 Any Non-secure System register access to an implemented trace register is trapped to Hyp mode, unless the access is trapped to EL1 by a **CPACR** or **NSACR** control, or the access is from Non-secure EL0 and the definition of the register in the appropriate trace architecture specification indicates that the register is not accessible from EL0. A trapped instruction generates:
- A Hyp Trap exception, if the exception is taken from Non-secure EL0 or EL1.
 - An Undefined Instruction exception taken to Hyp mode, if the exception is taken from Hyp mode.

If the implementation does not include a trace macrocell, or does not include a System register interface to the trace macrocell registers, it is IMPLEMENTATION DEFINED whether this bit:

- Is RES0.
- Is RES1.
- Can be written from Hyp mode, and from Secure Monitor mode when **SCR.NS** is 1.

If EL3 is implemented and is using AArch32, and the value of **NSACR.NSTRCDIS** is 1, in Non-secure state this field behaves as RAO/WI, regardless of its actual value.

Note

- The ETMv4 architecture does not permit EL0 to access the trace registers. If the implementation includes an ETMv4 implementation, EL0 accesses to the trace registers are UNDEFINED, and a resulting Undefined Instruction exception is higher priority than a HCPTR.TTA Hyp Trap exception.
- The architecture does not provide traps on trace register accesses through the optional memory-mapped external debug interface.

System register accesses to the trace registers can have side-effects. When a System register access is trapped, any side-effects that are normally associated with the access do not occur before the exception is taken.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to 0.

Bits [19:16]

Reserved, RES0.

TASE, bit [15]

Traps Non-secure execution of Advanced SIMD instructions to Hyp mode when the value of HCPTR.TCP10 is 0.

- 0 This control does not cause any instructions to be trapped.
- 1 When the value of HCPTR.TCP10 is 0, any attempt to execute an Advanced SIMD instruction in Non-secure state is trapped to Hyp mode, unless it is trapped to EL1 by a **CPACR** or **NSACR** control. A trapped instruction generates:
- A Hyp Trap exception, if the exception is taken from Non-secure EL0 or EL1.
 - An Undefined Instruction exception taken to Hyp mode, if the exception is taken from Hyp mode.

When the value of HCPTR.TCP10 is 1, the value of this field is ignored.

If the implementation does not include Advanced SIMD and floating-point functionality, this field is RES1. Otherwise, it is IMPLEMENTATION DEFINED whether this field is implemented as a RW field. If it is not implemented as a RW field, then it is RAZ/WI.

If EL3 is implemented and is using AArch32, and the value of **NSACR.NSASEDIS** is 1, in Non-secure state this field behaves as RAO/WI, regardless of its actual value. This applies even if the field is implemented as RAZ/WI.

For the list of instructions affected by this field, see *Controls of Advanced SIMD operation that do not apply to floating-point operation* on page E1-2746.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to 0.

Bit [14]

Reserved, RES0.

Bits [13:12]

Reserved, RES1.

TCP11, bit [11]

The value of this field is ignored. If this field is programmed with a different value to the TCP10 bit then this field is UNKNOWN on a direct read of the HCPTR.

If the implementation does not include Advanced SIMD and floating-point functionality, this field is RES1.

If EL3 is implemented and is using AArch32, and the value of **NSACR.cp10** is 0, in Non-secure state this field behaves as RAO/WI, regardless of its actual value.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to 0.

TCP10, bit [10]

Trap Non-secure accesses to Advanced SIMD and floating-point functionality to Hyp mode:

- | | |
|---|--|
| 0 | This control does not cause any instructions to be trapped. |
| 1 | Any attempted access to Advanced SIMD and floating-point functionality from Non-secure state is trapped to Hyp mode, unless it is trapped to EL1 by a CPACR or NSACR control. A trapped instruction generates: <ul style="list-style-type: none"> • A Hyp Trap exception, if the exception is taken from Non-secure EL0 or EL1. • An Undefined Instruction exception taken to Hyp mode, if the exception is taken from Hyp mode. |

The Advanced SIMD and floating-point features controlled by these fields are:

- Execution of any floating-point or Advanced SIMD instruction.
- Any access to the Advanced SIMD and floating-point registers D0-D31 and their views as S0-S31 and Q0-Q15.
- Any access to the **FPSCR**, **FPSID**, **MVFR0**, **MVFR1**, **MVFR2**, or **FPEXC** System registers.

If the implementation does not include Advanced SIMD and floating-point functionality, this field is RES1.

If EL3 is implemented and is using AArch32, and the value of **NSACR.cp10** is 0, in Non-secure state this field behaves as RAO/WI, regardless of its actual value.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to 0.

Bits [9:0]

Reserved, RES1.

Accessing the HCPTR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 4, <Rt>, c1, c1, 2	100	010	0001	1111	0001

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	-
x	0	1	-	-	RW	RW
x	1	1	-	n/a	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL3 is implemented and is using AArch64:
 - If `CPTR_EL3.TCPAC==1`, accesses to this register from EL2 are trapped to EL3.
- When EL2 is implemented and is using AArch64 and `(SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0)`:
 - If `HSTR_EL2.T1==1`, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and `(SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0)`:
 - If `HSTR_EL2.T1==1`, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and `SCR_EL3.NS == 1`:
 - If `HSTR.T1==1`, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

G6.2.60 HCR, Hyp Configuration Register

The HCR characteristics are:

Purpose

Provides configuration controls for virtualization, including defining whether various Non-secure operations are trapped to Hyp mode.

Configurations

AArch32 System register HCR is architecturally mapped to AArch64 System register [HCR_EL2](#)[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into EL2 with EL2 using AArch32, or into EL3 with EL3 using AArch32. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

Attributes

HCR is a 32-bit register.

Field descriptions

The HCR bit assignments are:

Bit [31]

Reserved, RES0.

TRVM, bit [30]

Trap Reads of Virtual Memory controls. Traps Non-secure EL1 reads of the virtual memory control registers to Hyp mode. The registers for which read accesses are trapped are as follows:

[SCTLR](#), [TTBR0](#), [TTBR1](#), [TTBCR](#), [TTBCR2](#), [DACR](#), [DFSR](#), [IFSR](#), [DFAR](#), [IFAR](#), [ADFSR](#), [AIFSR](#), [PRRR](#), [NMRR](#), [MAIR0](#), [MAIR1](#), [AMAIRO](#), [AMAIR1](#), [CONTEXTIDR](#).

0 This control does not cause any instructions to be trapped.

- 1 Non-secure EL1 read accesses to the specified Virtual Memory controls are trapped to Hyp mode.

When this register has an architecturally-defined reset value, this field resets to 0.

HCD, bit [29]

HVC instruction disable. Disables Non-secure state execution of HVC instructions.

- 0 HVC instruction execution is enabled at EL2 and Non-secure EL1.
- 1 HVC instructions are UNDEFINED at EL2 and Non-secure EL1. The Undefined Instruction exception is taken to the Exception level at which the HVC instruction is executed.

———— Note —————

HVC instructions are always UNDEFINED at EL0.

This bit is only implemented if EL3 is not implemented. Otherwise, it is RES0.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to 0.

Bit [28]

Reserved, RES0.

TGE, bit [27]

Trap General Exceptions, from Non-secure EL0.

- 0 This control has no effect on execution at EL0.
- 1 When the value of [SCR.NS](#) is 0, this control has no effect on execution at EL0. When the value of [SCR.NS](#) is 1, then:
- All exceptions that would be routed to EL1 are routed to EL2.
 - The [SCTLR.M](#) bit is treated as being 0 for all purposes other than returning the result of a direct read of [SCTLR](#).
 - The [HCR.{FMO, IMO, AMO}](#) bits are treated as being 1 for all purposes other than returning the result of a direct read of [HCR](#).
 - All virtual interrupts are disabled.
 - Any IMPLEMENTATION DEFINED mechanisms for signaling virtual interrupts are disabled.
 - An exception return to EL1 is treated as an illegal exception return.
 - Monitor mode execution of an MSR or CPS instruction that changes [CPSR.M](#) to a Non-secure EL1 mode is an illegal change to [PSTATE.M](#). For more information see [Illegal changes to PSTATE.M on page G1-4336](#).

Also, when [HCR.TGE](#) is 1:

- If EL3 is using AArch32, an attempt to change from a Secure PL1 mode to a Non-secure EL1 mode by changing [SCR.NS](#) from 0 to 1 results in [SCR.NS](#) remaining as 0.
- The [HDCR.{TDRA, TDOSA, TDA, TDE}](#) bits are ignored and treated as being 1 other than for the purpose of a direct read of [HDCR](#).

In the following cases the field resets to 0:

- The PE resets into EL3 with EL3 using AArch32.
- The PE resets into EL2 with EL2 using AArch32.

Otherwise, the field reset value is architecturally UNKNOWN.

When this register has an architecturally-defined reset value, this field resets to 0.

TVM, bit [26]

Trap Virtual Memory controls. Traps Non-secure EL1 writes to the virtual memory control registers to Hyp mode. The registers for which write accesses are trapped are as follows:

[SCTLR](#), [TTBR0](#), [TTBR1](#), [TTBCR](#), [TTBCR2](#), [DACR](#), [DFSR](#), [IFSR](#), [DFAR](#), [IFAR](#), [ADFSR](#), [AIFSR](#), [PRRR](#), [NMRR](#), [MAIRO](#), [MAIR1](#), [AMAIRO](#), [AMAIR1](#), [CONTEXTIDR](#).

- 0 This control does not cause any instructions to be trapped.
- 1 Non-secure EL1 write accesses to EL1 virtual memory control registers are trapped to Hyp mode.

When this register has an architecturally-defined reset value, this field resets to 0.

TTLB, bit [25]

Trap TLB maintenance instructions. Traps Non-secure EL1 execution of a TLBI instruction to Hyp mode. This applies to the following instructions:

[TLBIALLIS](#), [TLBIMVAIS](#), [TLBIASIDIS](#), [TLBIMVAAIS](#), [TLBIMVALIS](#), [TLBIMVAALIS](#), [ITLBIALL](#), [ITLBIMVA](#), [ITLBIASID](#), [DTLBIALL](#), [DTLBIMVA](#), [DTLBIASID](#), [TLBIALL](#), [TLBIMVA](#), [TLBIASID](#), [TLBIMVAA](#), [TLBIMVAL](#), [TLBIMVAAL](#)

- 0 This control does not cause any instructions to be trapped.
- 1 Non-secure EL1 accesses to TLB maintenance instructions are trapped to Hyp mode.

When this register has an architecturally-defined reset value, this field resets to 0.

TPU, bit [24]

Trap cache maintenance instructions that operate to the Point of Unification. Traps Non-secure EL1 execution of those cache maintenance instructions to Hyp mode. This applies to the following instructions:

[ICIMVAU](#), [ICIALLU](#), [ICIALUIS](#), [DCCMVAU](#).

———— **Note** —————

An Undefined Instruction exception generated at EL0 is higher priority than this trap to EL2, and these instructions are always UNDEFINED at EL0.

- 0 This control does not cause any instructions to be trapped.
- 1 Non-secure EL1 execution of the specified instructions is trapped to Hyp mode.

When this register has an architecturally-defined reset value, this field resets to 0.

TPC, bit [23]

Trap data or unified cache maintenance instructions that operate to the Point of Coherency. Traps Non-secure EL1 execution of those cache maintenance instructions to Hyp mode. This applies to the following instructions:

[DCIMVAC](#), [DCCIMVAC](#), [DCCMVAC](#).

———— **Note** —————

An Undefined Instruction exception generated at EL0 is higher priority than this trap to EL2, and these instructions are always UNDEFINED at EL0.

- 0 This control does not cause any instructions to be trapped.
- 1 Non-secure execution of the specified instructions is trapped to Hyp mode.

When this register has an architecturally-defined reset value, this field resets to 0.

TSW, bit [22]

Trap data or unified cache maintenance instructions that operate by Set/Way. Traps Non-secure EL1 execution of those cache maintenance instructions by set/way to Hyp mode. This applies to the following instructions:

[DCISW](#), [DCCSW](#), [DCCISW](#).

———— **Note** ————

An Undefined Instruction exception generated at EL0 is higher priority than this trap to EL2, and these instructions are always UNDEFINED at EL0.

- 0 This control does not cause any instructions to be trapped.
1 Non-secure execution of the specified instructions is trapped to Hyp mode.

When this register has an architecturally-defined reset value, this field resets to 0.

TAC, bit [21]

Trap Auxiliary Control Registers. Traps Non-secure EL1 accesses to the Auxiliary Control Registers to Hyp mode, from both Execution states. This applies to the following register accesses: [ACTLR](#) and, if implemented, [ACTLR2](#).

- 0 This control does not cause any instructions to be trapped.
1 Non-secure EL1 accesses to the specified registers are trapped to Hyp mode.

When this register has an architecturally-defined reset value, this field resets to 0.

TIDCP, bit [20]

Trap IMPLEMENTATION DEFINED functionality. Traps Non-secure EL1 accesses to the encodings for IMPLEMENTATION DEFINED System Registers to Hyp mode.

MCR and MRC instructions accessing the following encodings:

- All coproc==p15, CRn==c9, Opcode1 = {0-7}, CRm == {c0-c2, c5-c8}, opcode2 == {0-7}.
- All coproc==p15, CRn==c10, Opcode1 =={0-7}, CRm == {c0, c1, c4, c8}, opcode2 == {0-7}.
- All coproc==p15, CRn==c11, Opcode1=={0-7}, CRm == {c0-c8, c15}, opcode2 == {0-7}.

When HCR.TIDCP is set to 1, it is IMPLEMENTATION DEFINED whether any of this functionality accessed from Non-secure EL0 is trapped to Hyp mode. If it is not, it is UNDEFINED, and the PE takes an Undefined Instruction exception to Non-secure Undefined mode.

- 0 This control does not cause any instructions to be trapped.
1 Non-secure EL1 accesses to the specified System register encodings for IMPLEMENTATION DEFINED functionality are trapped to Hyp mode.

When this register has an architecturally-defined reset value, this field resets to 0.

TSC, bit [19]

Trap SMC instructions. Traps Non-secure EL1 execution of SMC instructions to Hyp mode.

- 0 This control does not cause any instructions to be trapped.
1 Any attempt to execute an SMC instruction at Non-secure EL1 is trapped to Hyp mode, regardless of the value of [SCR.SCD](#).

The ARMv8-A architecture permits, but does not require, this trap to apply to conditional SMC instructions that fail their condition code check, in the same way as with traps on other conditional instructions.

———— **Note** ————

- This trap is only implemented if the implementation includes EL3.
- SMC instructions are always UNDEFINED at PL0.
- This bit traps execution of the SMC instruction. It is not a routing control for the SMC exception. Hyp Trap exceptions and SMC exceptions have different preferred return addresses.

When this register has an architecturally-defined reset value, this field resets to 0.

TID3, bit [18]

Trap ID group 3. Traps Non-secure EL1 reads of the following registers to Hyp mode:

[ID_PFR0](#), [ID_PFR1](#), [ID_DFR0](#), [ID_AFR0](#), [ID_MMFR0](#), [ID_MMFR1](#), [ID_MMFR2](#), [ID_MMFR3](#), [ID_ISAR0](#), [ID_ISAR1](#), [ID_ISAR2](#), [ID_ISAR3](#), [ID_ISAR4](#), [ID_ISAR5](#), [MVFR0](#), [MVFR1](#), [MVFR2](#), and [ID_MMFR4](#), except that if [ID_MMFR4](#) is implemented as RAZ/WI then it is IMPLEMENTATION DEFINED whether accesses to [ID_MMFR4](#) are trapped.

Also an MRC access to any of the following encodings:

- coproc==p15, opc1 == 0, CRn == c0, CRm == {c3-c7}, opc2 == {0,1}.
- coproc==p15, opc1 == 0, CRn == c0, CRm == c3, opc2 == 2.
- coproc==p15, opc1 == 0, CRn == c0, CRm == c5, opc2 == {4,5}.

It is IMPLEMENTATION DEFINED whether this bit traps MRC accesses to the following encodings:

- coproc==p15, opc1 == 0, CRn == c0, CRm == c2, opc2 == 7.
- coproc==p15, opc1 == 0, CRn == c0, CRm == c3, opc2 == {3-7}.
- coproc==p15, opc1 == 0, CRn == c0, CRm == {c4, c6, c7}, opc2 == {2-7}.
- coproc==p15, opc1 == 0, CRn == c0, CRm == c5, opc2 == {2, 3, 6, 7}.

0 This control does not cause any instructions to be trapped.

1 The specified Non-secure EL1 read accesses to ID group 3 registers are trapped to Hyp mode.

When this register has an architecturally-defined reset value, this field resets to 0.

TID2, bit [17]

Trap ID group 2. Traps the following register accesses to Hyp mode:

- Non-secure EL1 and EL0 reads of the [CTR](#), [CCSIDR](#), [CLIDR](#), and [CSSELR](#).
- Non-secure EL1 and EL0 writes to the [CSSELR](#).

0 This control does not cause any instructions to be trapped.

1 The specified Non-secure EL1 and EL0 accesses to ID group 2 registers are trapped to Hyp mode.

When this register has an architecturally-defined reset value, this field resets to 0.

TID1, bit [16]

Trap ID group 1. Traps Non-secure EL1 reads of the following registers to Hyp mode:

[TCMTR](#), [TLBTR](#), [REVIDR](#), [AIDR](#).

0 This control does not cause any instructions to be trapped.

1 The specified Non-secure EL1 read accesses to ID group 1 registers are trapped to Hyp mode.

When this register has an architecturally-defined reset value, this field resets to 0.

TID0, bit [15]

Trap ID group 0. Traps the following register accesses to Hyp mode:

- Non-secure EL1 reads of the [JIDR](#) and [FPSID](#).
- If the [JIDR](#) is RAZ from Non-secure EL0, Non-secure EL0 reads of the [JIDR](#).

————— Note —————

- It is IMPLEMENTATION DEFINED whether the [JIDR](#) is RAZ or UNDEFINED at EL0. If it is UNDEFINED at EL0 then the Undefined Instruction exception takes precedence over this trap.
- The [FPSID](#) is not accessible at EL0.
- Writes to the [FPSID](#) are ignored, and not trapped by this control.

0 This control does not cause any instructions to be trapped.

- 1 The specified Non-secure EL1 read accesses to ID group 0 registers are trapped to Hyp mode.

When this register has an architecturally-defined reset value, this field resets to 0.

TWE, bit [14]

Traps Non-secure EL0 and EL1 execution of WFE instructions to Hyp mode:

- 0 This control does not cause any instructions to be trapped.
- 1 Any attempt to execute a WFE instruction at Non-secure EL0 or EL1 is trapped to Hyp mode, if the instruction would otherwise have caused the PE to enter a low-power state and it is not trapped by `SCTLR.nTWE`.

The attempted execution of a conditional WFE instruction is only trapped if the instruction passes its condition code check.

———— Note ————

Since a WFE can complete at any time, even without a Wakeup event, the traps on WFE are not guaranteed to be taken, even if the WFE is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

When this register has an architecturally-defined reset value, this field resets to 0.

TWI, bit [13]

Traps Non-secure EL0 and EL1 execution of WFI instructions to Hyp mode.

- 0 This control does not cause any instructions to be trapped.
- 1 Any attempt to execute a WFI instruction at Non-secure EL0 or EL1 is trapped to Hyp mode, if the instruction would otherwise have caused the PE to enter a low-power state and it is not trapped by `SCTLR.nTWI`.

The attempted execution of a conditional WFI instruction is only trapped if the instruction passes its condition code check.

———— Note ————

Since a WFI can complete at any time, even without a Wakeup event, the traps on WFI are not guaranteed to be taken, even if the WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

When this register has an architecturally-defined reset value, this field resets to 0.

DC, bit [12]

Default Cacheability.

- 0 This control has no effect on the Non-secure EL1&0 translation regime.
- 1 In Non-secure state:
- The `SCTLR.M` field behaves as 0 for all purposes other than a direct read of the value of the field.
 - The `HCR.VM` field behaves as 1 for all purposes other than a direct read of the value of the field.
 - The memory type produced by the first stage of the EL1&0 translation regime is Normal Non-Shareable, Inner Write-Back Read-Allocate Write-Allocate, Outer Write-Back Read-Allocate Write-Allocate.

This field has no effect on the EL2 and EL3 translation regimes.

This field is permitted to be cached in a TLB.

When this register has an architecturally-defined reset value, this field resets to 0.

BSU, bits [11:10]

Barrier Shareability upgrade. This field determines the minimum shareability domain that is applied to any barrier instruction executed from Non-secure EL1 or Non-secure EL0:

00	No effect
01	Inner Shareable
10	Outer Shareable
11	Full system

This value is combined with the specified level of the barrier held in its instruction, using the same principles as combining the shareability attributes from two stages of address translation.

When this register has an architecturally-defined reset value, this field resets to 0.

FB, bit [9]

Force broadcast. Causes the following instructions to be broadcast within the Inner Shareable domain when executed from Non-secure EL1:

[BPIALL](#), [TLBIALL](#), [TLBIMVA](#), [TLBIASID](#), [DTLBIALL](#), [DTLBIMVA](#), [DTLBIASID](#), [ITLBIALL](#), [ITLBIMVA](#), [ITLBIASID](#), [TLBIMVAA](#), [ICIALLU](#), [TLBIMVAL](#), [TLBIMVAAL](#).

0	This field has no effect on the operation of the specified instructions.
1	When one of the specified instruction is executed at Non-secure EL1, the instruction is broadcast within the Inner Shareable shareability domain.

When this register has an architecturally-defined reset value, this field resets to 0.

VA, bit [8]

Virtual SError interrupt exception.

0	This mechanism is not making a virtual SError interrupt pending.
1	A virtual SError interrupt is pending because of this mechanism.

The virtual SError interrupt is enabled only when the value of HCR.{TGE, AMO} is {0, 1}.

The Guest OS cannot distinguish the virtual exception from the corresponding physical exception.

When this register has an architecturally-defined reset value, this field resets to 0.

VI, bit [7]

Virtual IRQ exception.

0	This mechanism is not making a virtual IRQ pending.
1	A virtual IRQ is pending because of this mechanism.

The virtual IRQ is enabled only when the value of HCR.{TGE, IMO} is {0, 1}.

The Guest OS cannot distinguish the virtual exception from the corresponding physical exception.

When this register has an architecturally-defined reset value, this field resets to 0.

VF, bit [6]

Virtual FIQ exception.

0	This mechanism is not making a virtual FIQ pending.
1	A virtual FIQ is pending because of this mechanism.

The virtual FIQ is enabled only when the value of HCR.{TGE, FMO} is {0, 1}.

The Guest OS cannot distinguish the virtual exception from the corresponding physical exception.

When this register has an architecturally-defined reset value, this field resets to 0.

AMO, bit [5]

SError interrupt Mask Override. When this bit is set to 1, it overrides the effect of [CPSR.A](#), and enables virtual exception signaling by the VA bit.

If the value of HCR.TGE is 0, then Virtual SError Interrupts are enabled in Non-secure state.

If the value of HCR.TGE is 1, then in Non-secure state the HCR.AMO bit behaves as 1 for all purposes other than a direct read of the value of the bit.

When this register has an architecturally-defined reset value, this field resets to 0.

IMO, bit [4]

IRQ Mask Override. When this bit is set to 1, it overrides the effect of CPSR.I, and enables virtual exception signaling by the VI bit.

If the value of HCR.TGE is 0, then Virtual IRQ interrupts are enabled in the Non-secure state.

If the value of HCR.TGE is 1, then in Non-secure state the HCR.IMO bit behaves as 1 for all purposes other than a direct read of the value of the bit.

When this register has an architecturally-defined reset value, this field resets to 0.

FMO, bit [3]

FIQ Mask Override. When this bit is set to 1, it overrides the effect of CPSR.F, and enables virtual exception signaling by the VF bit.

If the value of HCR.TGE is 0, then Virtual FIQ interrupts are enabled in the Non-secure state.

If the value of HCR.TGE is 1, then in Non-secure state the HCR.FMO bit behaves as 1 for all purposes other than a direct read of the value of the bit.

When this register has an architecturally-defined reset value, this field resets to 0.

PTW, bit [2]

Protected Table Walk. In the Non-secure PL1&0 translation regime, a translation table access made as part of a stage 1 translation table walk is subject to a stage 2 translation. The combining of the memory type attributes from the two stages of translation means the access might be made to a type of Device memory. If this occurs then the value of this bit determines the behavior:

0 The translation table walk occurs as if it is to Normal Non-cacheable memory. This means it can be made speculatively.

1 The memory access generates a stage 2 Permission fault.

This field is permitted to be cached in a TLB.

When this register has an architecturally-defined reset value, this field resets to 0.

SWIO, bit [1]

Set/Way Invalidation Override. Causes Non-secure EL1 execution of the data cache invalidate by set/way instructions to perform a data cache clean and invalidate by set/way.

0 This control has no effect on the operation of data cache invalidate by set/way instructions.

1 Data cache invalidate by set/way instructions perform a data cache clean and invalidate by set/way.

When this bit is set to 1, DCISW performs the same invalidation as a DCCISW instruction.

As a result of changes to the behavior of DCISW, this bit is redundant in ARMv8. This bit can be implemented as RES1.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to 0.

VM, bit [0]

Virtualization enable. Enables stage 2 address translation for the Non-secure EL1&0 translation regime. Possible values of this bit are:

0 Non-secure EL1&0 stage 2 address translation disabled.

1 Non-secure EL1&0 stage 2 address translation enabled.

If the HCR.DC bit is set to 1, then the behavior of the PE when executing in a Non-secure mode other than Hyp mode is consistent with HCR.VM being 1, regardless of the actual value of HCR.VM, other than the value returned by an explicit read of HCR.VM.

When the value of this bit is 1, data cache invalidate instructions executed at Non-secure EL1 perform a data cache clean and invalidate. For the invalidate by set/way instruction this behavior applies regardless of the value of the HCR.SWIO bit.

This bit is permitted to be cached in a TLB.

When this register has an architecturally-defined reset value, this field resets to 0.

Accessing the HCR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 4, <Rt>, c1, c1, 0	100	000	0001	1111	0001

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	-
x	0	1	-	-	RW	RW
x	1	1	-	n/a	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If HSTR_EL2.T1==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If HSTR_EL2.T1==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HSTR.T1==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

G6.2.61 HCR2, Hyp Configuration Register 2

The HCR2 characteristics are:

Purpose

Provides additional configuration controls for virtualization.

Configurations

AArch32 System register HCR2 is architecturally mapped to AArch64 System register [HCR_EL2](#)[63:32].

If EL2 is not implemented, this register is RES0 from EL3.

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into EL2 with EL2 using AArch32, or into EL3 with EL3 using AArch32. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

Attributes

HCR2 is a 32-bit register.

Field descriptions

The HCR2 bit assignments are:

Bits [31:7]

Reserved, RES0.

MIOCNCNE, bit [6]

Mismatched Inner/Outer Cacheable Non-Coherency Enable, for the Non-secure PL1&0 translation regime.

- 0 For the Non-secure PL1&0 translation regime, for permitted accesses to a memory location that use a common definition of the Shareability and Cacheability of the location, there must be no loss of coherency if the Inner Cacheability attribute for those accesses differs from the Outer Cacheability attribute.
- 1 For the Non-secure PL1&0 translation regime, for permitted accesses to a memory location that use a common definition of the Shareability and Cacheability of the location, there might be a loss of coherency if the Inner Cacheability attribute for those accesses differs from the Outer Cacheability attribute.

For more information see [Mismatched memory attributes](#) on page E2-2792.

The value of this field has no effect on translation regimes other than the Non-secure PL1&0 translation regime.

This field can be implemented as RAZ/WI.

If this field is implemented as an RW field, it resets to a value that is architecturally UNKNOWN.

TEA, bit [5]

Route synchronous External Abort exceptions to EL2. If the RAS Extension is implemented, the possible values of this bit are:

- 0 Do not route synchronous External Abort exceptions from Non-secure EL0 and EL1 to EL2.
- 1 Route synchronous External Abort exceptions from Non-secure EL0 and EL1 to EL2, if not routed to EL3.

This bit resets to zero on a Warm reset into AArch32 state.

When the RAS Extension is not implemented, this field is RES0.

When this register has an architecturally-defined reset value, this field resets to 0.

TERR, bit [4]

Trap Error record accesses. If the RAS Extension is implemented, the possible values of this bit are:

- 0 Do not trap accesses to error record registers from Non-secure EL1 to EL2.
- 1 Accesses to the ER* registers from Non-secure EL1 generate a Trap exception to EL2.

This bit resets to zero on a Warm reset into AArch32 state.

When the RAS Extension is not implemented, this field is RES0.

When this register has an architecturally-defined reset value, this field resets to 0.

Bits [3:2]

Reserved, RES0.

ID, bit [1]

Stage 2 Instruction access cacheability disable. For the Non-secure PL1&0 translation regime, when `HCR.VM==1`, this control forces all stage 2 translations for instruction accesses to Normal memory to be Non-cacheable.

- 0 This control has no effect on stage 2 of the Non-secure PL1&0 translation regime.
- 1 For the Non-secure PL1&0 translation regime, forces all stage 2 translations for instruction accesses to Normal memory to be Non-cacheable.

This bit has no effect on the EL2 translation regime.

When this register has an architecturally-defined reset value, this field resets to 0.

CD, bit [0]

Stage 2 Data access cacheability disable. When `HCR.VM==1`, this forces all stage 2 translations for data accesses and translation table walks to Normal memory to be Non-cacheable for the Non-secure PL1&0 translation regime.

- 0 This control has no effect on stage 2 of the Non-secure PL1&0 translation regime for data accesses and translation table walks.
- 1 For the Non-secure PL1&0 translation regime, forces all stage 2 translations for data accesses and translation table walks to Normal memory to be Non-cacheable.

This bit has no effect on the EL2 translation regime.

When this register has an architecturally-defined reset value, this field resets to 0.

Accessing the HCR2

This register can be read using MRC with the following syntax:

```
MRC <syntax>
```

This register can be written using MCR with the following syntax:

```
MCR <syntax>
```

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 4, <Rt>, c1, c1, 4	100	100	0001	1111	0001

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	-
x	0	1	-	-	RW	RW
x	1	1	-	n/a	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If HSTR_EL2.T1==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If HSTR_EL2.T1==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HSTR.T1==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

G6.2.62 HDFAR, Hyp Data Fault Address Register

The HDFAR characteristics are:

Purpose

Holds the virtual address of the faulting address that caused a synchronous Data Abort exception that is taken to Hyp mode.

Configurations

AArch32 System register HDFAR is architecturally mapped to AArch64 System register [FAR_EL2](#)[31:0].

AArch32 System register HDFAR is architecturally mapped to AArch32 System register [DFAR](#) (S) when EL2 is implemented.

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

HDFAR is a 32-bit register.

Field descriptions

The HDFAR bit assignments are:

Bits [31:0]

VA of faulting address of synchronous Data Abort exception taken to Hyp mode.

On a Prefetch Abort exception, this register is UNKNOWN.

Any execution in a Non-secure EL1 or Non-secure EL0 mode makes this register UNKNOWN.

Accessing the HDFAR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 4, <Rt>, c6, c0, 0	100	000	0110	1111	0000

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	-
x	0	1	-	-	RW	RW
x	1	1	-	n/a	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If [HSTR_EL2.T6](#)==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If [HSTR_EL2.T6](#)==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If [HSTR.T6](#)==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

G6.2.63 HIFAR, Hyp Instruction Fault Address Register

The HIFAR characteristics are:

Purpose

Holds the virtual address of the faulting address that caused a synchronous Prefetch Abort exception that is taken to Hyp mode.

Configurations

AArch32 System register HIFAR is architecturally mapped to AArch64 System register [FAR_EL2](#)[63:32].

AArch32 System register HIFAR is architecturally mapped to AArch32 System register [IFAR](#) (S) when EL2 is implemented.

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

HIFAR is a 32-bit register.

Field descriptions

The HIFAR bit assignments are:

Bits [31:0]

VA of faulting address of synchronous Prefetch Abort exception taken to Hyp mode.

On a Data Abort exception, this register is UNKNOWN.

Any execution in a Non-secure EL1 or Non-secure EL0 mode makes this register UNKNOWN.

Accessing the HIFAR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 4, <Rt>, c6, c0, 2	100	010	0110	1111	0000

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	-
x	0	1	-	-	RW	RW
x	1	1	-	n/a	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If [HSTR_EL2.T6](#)==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If [HSTR_EL2.T6](#)==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If [HSTR.T6](#)==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

G6.2.64 HMAIR0, Hyp Memory Attribute Indirection Register 0

The HMAIR0 characteristics are:

Purpose

Along with [HMAIR1](#), provides the memory attribute encodings corresponding to the possible AttrIdx values in a Long-descriptor format translation table entry for stage 1 translations for memory accesses from Hyp mode.

AttrIdx[2] indicates the HMAIR register to be used:

- When AttrIdx[2] is 0, HMAIR0 is used.
- When AttrIdx[2] is 1, [HMAIR1](#) is used.

Configurations

AArch32 System register HMAIR0 is architecturally mapped to AArch64 System register [MAIR_EL2](#)[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

HMAIR0 is a 32-bit register.

Field descriptions

The HMAIR0 bit assignments are:

When *TTBCR.EAE*==1:

Attr<n>, bits [8n+7:8n], for n = 0 to 3

The memory attribute encoding for an AttrIdx[2:0] entry in a Long descriptor format translation table entry, where:

- AttrIdx[2:0] gives the value of <n> in Attr<n>.
- AttrIdx[2] defines which MAIR to access. Attr7 to Attr4 are in MAIR1, and Attr3 to Attr0 are in MAIR0.

Bits [7:4] are encoded as follows:

Attr<n>[7:4]	Meaning
0000	Device memory. See encoding of Attr<n>[3:0] for the type of Device memory.
00RW, RW not 00	Normal memory, Outer Write-Through Transient
0100	Normal memory, Outer Non-cacheable
01RW, RW not 00	Normal memory, Outer Write-Back Transient
10RW	Normal memory, Outer Write-Through Non-transient
11RW	Normal memory, Outer Write-Back Non-transient

R = Outer Read-Allocate policy, W = Outer Write-Allocate policy.

The meaning of bits [3:0] depends on the value of bits [7:4]:

Attr<n>[3:0]	Meaning when Attr<n>[7:4] is 0000	Meaning when Attr<n>[7:4] is not 0000
0000	Device-nGnRnE memory	UNPREDICTABLE
00RW, RW not 00	UNPREDICTABLE	Normal memory, Inner Write-Through Transient
0100	Device-nGnRE memory	Normal memory, Inner Non-cacheable
01RW, RW not 00	UNPREDICTABLE	Normal memory, Inner Write-Back Transient
1000	Device-nGRE memory	Normal memory, Inner Write-Through Non-transient (RW=00)
10RW, RW not 00	UNPREDICTABLE	Normal memory, Inner Write-Through Non-transient
1100	Device-GRE memory	Normal memory, Inner Write-Back Non-transient (RW=00)
11RW, RW not 00	UNPREDICTABLE	Normal memory, Inner Write-Back Non-transient

R = Inner Read-Allocate policy, W = Inner Write-Allocate policy.

The R and W bits in some Attr<n> fields have the following meanings:

R or W	Meaning
0	No Allocate
1	Allocate

Accessing the HMAIR0

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 4, <Rt>, c10, c2, 0	100	000	1010	1111	0010

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	-
x	0	1	-	-	RW	RW
x	1	1	-	n/a	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 0)$:
 - If $HSTR_EL2.T10 == 1$, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 1) \ \&\& \ (HCR_EL2.TGE == 0)$:
 - If $HSTR_EL2.T10 == 1$, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $HSTR.T10 == 1$, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

G6.2.65 HMAIR1, Hyp Memory Attribute Indirection Register 1

The HMAIR1 characteristics are:

Purpose

Along with [HMAIR0](#), provides the memory attribute encodings corresponding to the possible AttrIdx values in a Long-descriptor format translation table entry for stage 1 translations for memory accesses from Hyp mode.

AttrIdx[2] indicates the HMAIR register to be used:

- When AttrIdx[2] is 0, [HMAIR0](#) is used.
- When AttrIdx[2] is 1, HMAIR1 is used.

Configurations

AArch32 System register HMAIR1 is architecturally mapped to AArch64 System register [MAIR_EL2](#)[63:32].

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

HMAIR1 is a 32-bit register.

Field descriptions

The HMAIR1 bit assignments are:

When *TTBCR.EAE*==1:

Attr<n>, bits [8(n-4)+7:8(n-4)], for n = 4 to 7

The memory attribute encoding for an AttrIdx[2:0] entry in a Long descriptor format translation table entry, where:

- AttrIdx[2:0] gives the value of <n> in Attr<n>.
- AttrIdx[2] defines which MAIR to access. Attr7 to Attr4 are in MAIR1, and Attr3 to Attr0 are in MAIR0.

Bits [7:4] are encoded as follows:

Attr<n>[7:4]	Meaning
0000	Device memory. See encoding of Attr<n>[3:0] for the type of Device memory.
00RW, RW not 00	Normal memory, Outer Write-Through Transient
0100	Normal memory, Outer Non-cacheable
01RW, RW not 00	Normal memory, Outer Write-Back Transient
10RW	Normal memory, Outer Write-Through Non-transient
11RW	Normal memory, Outer Write-Back Non-transient

R = Outer Read-Allocate policy, W = Outer Write-Allocate policy.

The meaning of bits [3:0] depends on the value of bits [7:4]:

Attr<n>[3:0]	Meaning when Attr<n>[7:4] is 0000	Meaning when Attr<n>[7:4] is not 0000
0000	Device-nGnRnE memory	UNPREDICTABLE
00RW, RW not 00	UNPREDICTABLE	Normal memory, Inner Write-Through Transient
0100	Device-nGnRE memory	Normal memory, Inner Non-cacheable
01RW, RW not 00	UNPREDICTABLE	Normal memory, Inner Write-Back Transient
1000	Device-nGRE memory	Normal memory, Inner Write-Through Non-transient (RW=00)
10RW, RW not 00	UNPREDICTABLE	Normal memory, Inner Write-Through Non-transient
1100	Device-GRE memory	Normal memory, Inner Write-Back Non-transient (RW=00)
11RW, RW not 00	UNPREDICTABLE	Normal memory, Inner Write-Back Non-transient

R = Inner Read-Allocate policy, W = Inner Write-Allocate policy.

The R and W bits in some Attr<n> fields have the following meanings:

R or W	Meaning
0	No Allocate
1	Allocate

Accessing the HMAIR1

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 4, <Rt>, c10, c2, 1	100	001	1010	1111	0010

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	-
x	0	1	-	-	RW	RW
x	1	1	-	n/a	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 0)$:
 - If $HSTR_EL2.T10 == 1$, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 1) \ \&\& \ (HCR_EL2.TGE == 0)$:
 - If $HSTR_EL2.T10 == 1$, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $HSTR.T10 == 1$, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

G6.2.66 HPFAR, Hyp IPA Fault Address Register

The HPFAR characteristics are:

Purpose

Holds the faulting IPA for some aborts on a stage 2 translation taken to Hyp mode.

Configurations

AArch32 System register HPFAR is architecturally mapped to AArch64 System register [HPFAR_EL2](#)[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

HPFAR is a 32-bit register.

Field descriptions

The HPFAR bit assignments are:

Execution in any Non-secure mode other than Hyp mode makes this register UNKNOWN.

FIPA[39:12], bits [31:4]

Bits [39:12] of the faulting intermediate physical address.

Bits [3:0]

Reserved, RES0.

Accessing the HPFAR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 4, <Rt>, c6, c0, 4	100	100	0110	1111	0000

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	-
x	0	1	-	-	RW	RW
x	1	1	-	n/a	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If [HSTR_EL2.T6](#)==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If [HSTR_EL2.T6](#)==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If [HSTR.T6](#)==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

G6.2.67 HRMR, Hyp Reset Management Register

The HRMR characteristics are:

Purpose

If EL2 is the highest implemented Exception level and this register is implemented:

- A write to the register at EL2 can request a Warm reset.
- If EL2 can use AArch32 and AArch64, this register specifies the Execution state that the PE boots into on a Warm reset.

Configurations

AArch32 System register HRMR is architecturally mapped to AArch64 System register [RMR_EL2](#).

Only implemented if EL2 is the highest implemented Exception level. In this case:

- If EL2 can use AArch32 and AArch64 then this register must be implemented.
- If EL2 cannot use AArch64 then it is IMPLEMENTATION DEFINED whether the register is implemented.

See the field descriptions for the reset values. These apply whenever the register is implemented.

Attributes

HRMR is a 32-bit register.

Field descriptions

The HRMR bit assignments are:

Bits [31:2]

Reserved, RES0.

RR, bit [1]

Reset Request. Setting this bit to 1 requests a Warm reset.

This field resets to 0 on a Warm or Cold reset.

AA64, bit [0]

When EL2 can use AArch64, determines which Execution state the PE boots into after a Warm reset:

- 0 AArch32.
- 1 AArch64.

On coming out of the Warm reset, execution starts at the IMPLEMENTATION DEFINED reset vector address of the specified Execution state.

If EL2 cannot use AArch64 this bit is RAZ/WI.

When implemented as a RW field, this field resets to 0 on a Cold reset.

Accessing the HRMR

This register can be read using MRC with the following syntax:

MCR <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 4, <Rt>, c12, c0, 2	100	010	1100	1111	0000

Accessibility

The register is accessible in software as follows:

Configuration	Control			Accessibility			
	E2H	TGE	NS	EL0	EL1	EL2	EL3
EL2 is the highest implemented Exception level.	x	0	1	-	-	RW	n/a
EL2 is the highest implemented Exception level.	x	1	1	-	n/a	RW	n/a

When HRMR is not implemented, the encoding for this register is UNDEFINED.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If HSTR_EL2.T12==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If HSTR_EL2.T12==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HSTR.T12==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

G6.2.68 HSCTLR, Hyp System Control Register

The HSCTLR characteristics are:

Purpose

Provides top level control of the system operation in Hyp mode.

Configurations

AArch32 System register HSCTLR is architecturally mapped to AArch64 System register [SCTLR_EL2](#).

If EL2 is not implemented, this register is RES0 from EL3.

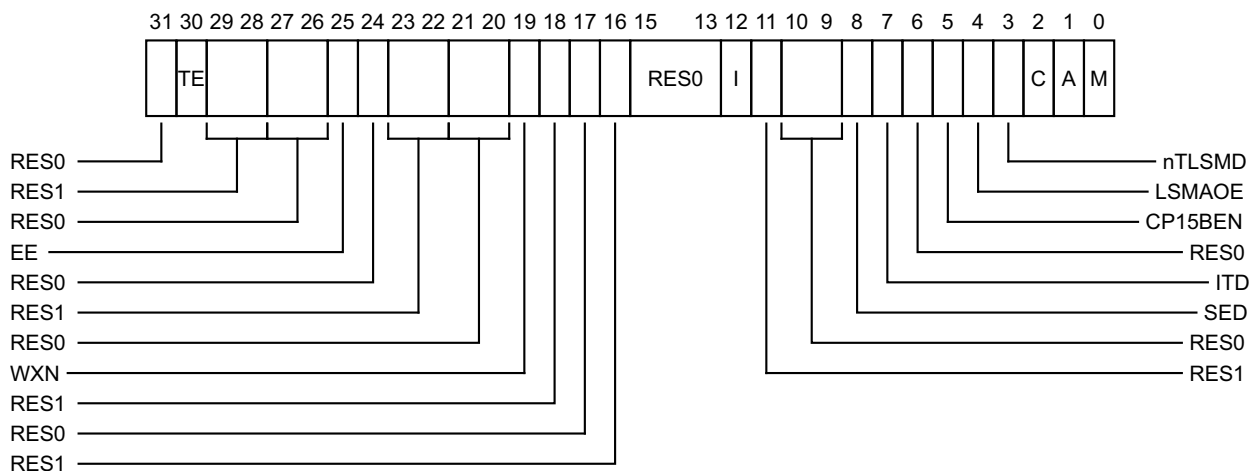

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into EL2 with EL2 using AArch32. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

Attributes

HSCTLR is a 32-bit register.

Field descriptions

The HSCTLR bit assignments are:

Bit [31]

Reserved, RES0.

TE, bit [30]

T32 Exception Enable. This bit controls whether exceptions to EL2 are taken to A32 or T32 state:

0 Exceptions, including reset, taken to A32 state.

1 Exceptions, including reset, taken to T32 state.

This field resets to a value that is architecturally UNKNOWN.

Bits [29:28]

Reserved, RES1.

Bits [27:26]

Reserved, RES0.

EE, bit [25]

The value of the PSTATE.E bit on entry to Hyp mode, the endianness of stage 1 translation table walks in the EL2 translation regime, and the endianness of stage 2 translation table walks in the PL1&0 translation regime.

The possible values of this bit are:

- 0 Little-endian. PSTATE.E is cleared to 0 on entry to Hyp mode. Stage 1 translation table walks in the EL2 translation regime, and stage 2 translation table walks in the PL1&0 translation regime are little-endian.
- 1 Big-endian. PSTATE.E is set to 1 on entry to Hyp mode. Stage 1 translation table walks in the EL2 translation regime, and stage 2 translation table walks in the PL1&0 translation regime are big-endian.

If an implementation does not provide Big-endian support at Exception Levels higher than EL0, this bit is RES0.

If an implementation does not provide Little-endian support at Exception Levels higher than EL0, this bit is RES1.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to an IMPLEMENTATION DEFINED value.

Bit [24]

Reserved, RES0.

Bits [23:22]

Reserved, RES1.

Bits [21:20]

Reserved, RES0.

WXN, bit [19]

Write permission implies XN (Execute-never). For the EL2 translation regime, this bit can force all memory regions that are writable to be treated as XN. The possible values of this bit are:

- 0 This control has no effect on memory access permissions.
- 1 Any region that is writable in the EL2 translation regime is forced to XN for accesses from software executing at EL2.

The WXN bit is permitted to be cached in a TLB.

This field resets to a value that is architecturally UNKNOWN.

Bit [18]

Reserved, RES1.

Bit [17]

Reserved, RES0.

Bit [16]

Reserved, RES1.

Bits [15:13]

Reserved, RES0.

I, bit [12]

Instruction access Cacheability control, for accesses at EL2:

- 0 All instruction access to Normal memory from EL2 are Non-cacheable for all levels of instruction and unified cache.

If the value of HSCTLR.M is 0, instruction accesses from stage 1 of the EL2 translation regime are to Normal, Outer Shareable, Inner Non-cacheable, Outer Non-cacheable memory.

- 1 All instruction access to Normal memory from EL2 can be cached at all levels of instruction and unified cache.
- If the value of HSCTLR.M is 0, instruction accesses from stage 1 of the EL2 translation regime are to Normal, Outer Shareable, Inner Write-Through, Outer Write-Through memory.

This bit has no effect on the PL1&0 translation regime.

When this register has an architecturally-defined reset value, this field resets to 0.

Bit [11]

Reserved, RES1.

Bits [10:9]

Reserved, RES0.

SED, bit [8]

SETEND instruction disable. Disables SETEND instructions at EL2.

- 0 SETEND instruction execution is enabled at EL2.
- 1 SETEND instructions are UNDEFINED at EL2.

If the implementation does not support mixed-endian operation at EL2, this bit is RES1.

If this field is implemented as an RW field, it resets to a value that is architecturally UNKNOWN.

ITD, bit [7]

IT Disable. Disables some uses of IT instructions at EL2.

- 0 All IT instruction functionality is enabled at EL2.
- 1 Any attempt at EL2 to execute any of the following is UNDEFINED:
- All encodings of the IT instruction with hw1[3:0] != 1000.
 - All encodings of the subsequent instruction with the following values for hw1:
 - 11xxxxxxxxxxxxx
All 32-bit instructions, and the 16-bit instructions B, UDF, SVC, LDM, and STM.
 - 1011xxxxxxxxxxxxx
All instructions in *Miscellaneous 16-bit instructions on page F3-2883*.
 - 10100xxxxxxxxxxxx
ADD Rd, PC, #imm
 - 01001xxxxxxxxxxxx
LDR Rd, [PC, #imm]
 - 0100x1xxx1111xxx
ADD Rdn, PC; CMP Rn, PC; MOV Rd, PC; BX PC; BLX PC.
 - 010001xx1xxxx111
ADD PC, Rm; CMP PC, Rm; MOV PC, Rm. This pattern also covers UNPREDICTABLE cases with BLX Rn.

These instructions are always UNDEFINED, regardless of whether they would pass or fail the condition code check that applies to them as a result of being in an IT block.

It is IMPLEMENTATION DEFINED whether the IT instruction is treated as:

- A 16-bit instruction, that can only be followed by another 16-bit instruction.
- The first half of a 32-bit instruction.

This means that, for the situations that are UNDEFINED, either the second 16-bit instruction or the 32-bit instruction is UNDEFINED.

An implementation might vary dynamically as to whether IT is treated as a 16-bit instruction or the first half of a 32-bit instruction.

If an instruction in an active IT block that would be disabled by this field sets this field to 1 then behavior is CONSTRAINED UNPREDICTABLE. For more information see [Changes to an ITD control by an instruction in an IT block on page E1-2738](#)

ITD is optional, but if it is implemented in the SCTLR then it must also be implemented in the HSCTLR. If it is not implemented then this bit is RAZ/WI.

If this field is implemented as an RW field, it resets to a value that is architecturally UNKNOWN.

Bit [6]

Reserved, RES0.

CP15BEN, bit [5]

System instruction memory barrier enable. Enables accesses to the DMB, DSB, and ISB System instructions in the (coproc==1111) encoding space from EL2:

- 0 EL2 execution of the [CP15DMB](#), [CP15DSB](#), and [CP15ISB](#) instructions is UNDEFINED.
- 1 EL2 execution of the [CP15DMB](#), [CP15DSB](#), and [CP15ISB](#) instructions is enabled.

CP15BEN is optional, but if it is implemented in the SCTLR then it must also be implemented in the HSCTLR. If it is not implemented then this bit is RAO/WI.

If this field is implemented as an RW field, it resets to a value that is architecturally UNKNOWN.

LSMAOE, bit [4]

In ARMv8.2

Load Multiple and Store Multiple Atomicity and Ordering Enable. When the OPTIONAL feature [ARMv8.2-LSMAOC](#) is implemented, defined values are:

- 0 For all memory accesses at EL2, A32 and T32 Load Multiple and Store Multiple can have an interrupt taken during the sequence memory accesses, and the memory accesses are not required to be ordered.
- 1 The ordering and interrupt behavior of A32 and T32 Load Multiple and Store Multiple at EL2 is as defined for ARMv8.0.

This bit is permitted to be cached in a TLB.

If this bit is not implemented, it is RES1.

When this register has an architecturally-defined reset value, this field resets to 1.

In ARMv8.1 and ARMv8.0.

Reserved, RES1.

nTLSMD, bit [3]

In ARMv8.2

No Trap Load Multiple and Store Multiple to Device-nGRE/Device-nGnRE/Device-nGnRnE memory. When the OPTIONAL feature [ARMv8.2-LSMAOC](#) is implemented, defined values are:

- 0 All memory accesses by A32 and T32 Load Multiple and Store Multiple at EL2 that are marked at stage 1 as Device-nGRE/Device-nGnRE/Device-nGnRnE memory are trapped and generate a stage 1 Alignment fault.
- 1 All memory accesses by A32 and T32 Load Multiple and Store Multiple at EL2 that are marked at stage 1 as Device-nGRE/Device-nGnRE/Device-nGnRnE memory are not trapped.

This bit is permitted to be cached in a TLB.

If this bit is not implemented, it is RES1.

When this register has an architecturally-defined reset value, this field resets to 1.

In ARMv8.1 and ARMv8.0.

Reserved, RES1.

C, bit [2]

Cacheability control, for data accesses at EL2:

- 0 All data access to Normal memory from EL2, and all accesses to the EL2 translation tables, are Non-cacheable for all levels of data and unified cache.
- 1 All data access to Normal memory from EL2, and all accesses to the EL2 translation tables, can be cached at all levels of data and unified cache.

This bit has no effect on the PL1&0 translation regime.

When this register has an architecturally-defined reset value, this field resets to 0.

A, bit [1]

Alignment check enable. This is the enable bit for Alignment fault checking at EL2:

- 0 Alignment fault checking disabled when executing at EL2.
Instructions that load or store one or more registers, other than load/store exclusive and load-acquire/store-release, do not check that the address being accessed is aligned to the size of the data element or data elements being accessed.
- 1 Alignment fault checking enabled when executing at EL2.
All instructions that load or store one or more registers have an alignment check that the address being accessed is aligned to the size of the data element or data elements being accessed. If this check fails it causes an Alignment fault, which is taken as a Data Abort exception.

Load/store exclusive and load-acquire/store-release instructions have an alignment check regardless of the value of the A bit.

This field resets to a value that is architecturally UNKNOWN.

M, bit [0]

MMU enable for EL2 stage 1 address translation. Possible values of this bit are:

- 0 EL2 stage 1 address translation disabled.
See the HSCTLR.I field for the behavior of instruction accesses to Normal memory.
- 1 EL2 stage 1 address translation enabled.

When this register has an architecturally-defined reset value, this field resets to 0.

Accessing the HSCTLR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 4, <Rt>, c1, c0, 0	100	000	0001	1111	0000

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	-
x	0	1	-	-	RW	RW
x	1	1	-	n/a	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If [HSTR_EL2.T1](#)==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If [HSTR_EL2.T1](#)==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If [HSTR.T1](#)==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

G6.2.69 HSR, Hyp Syndrome Register

The HSR characteristics are:

Purpose

Holds syndrome information for an exception taken to Hyp mode.

Configurations

AArch32 System register HSR is architecturally mapped to AArch64 System register [ESR_EL2](#).

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

HSR is a 32-bit register.

Field descriptions

The HSR bit assignments are:

Execution in any Non-secure PE mode other than Hyp mode makes this register UNKNOWN.

When an UNPREDICTABLE instruction is treated as UNDEFINED, and the exception is taken to EL2, the value of HSR is UNKNOWN. The value written to HSR must be consistent with a value that could be created as a result of an exception from the same Exception level that generated the exception as a result of a situation that is not UNPREDICTABLE at that Exception level, in order to avoid the possibility of a privilege violation.

EC, bits [31:26]

Exception Class. Indicates the reason for the exception that this register holds information about. Possible values of this field are:

EC == 000000

Unknown reason.

See [ISS encoding for exceptions with an unknown reason](#).

EC == 000001

Trapped WFI or WFE instruction execution.

Conditional WFE and WFI instructions that fail their condition code check do not cause an exception.

See [ISS encoding for an exception from a WFI or WFE instruction](#).

EC == 000011

Trapped MCR or MRC access with (coproc==1111) that is not reported using EC 0b000000.

See [ISS encoding for an exception from an MCR or MRC access](#).

EC == 000100

Trapped MCRR or MRRC access with (coproc==1111) that is not reported using EC 0b000000.

See [ISS encoding for an exception from an MCRR or MRRC access](#).

EC == 000101

Trapped MCR or MRC access with (coproc==1110).

See [ISS encoding for an exception from an MCR or MRC access](#).

EC == 000110

Trapped LDC or STC access.

The only architected uses of these instructions are:

- An STC to write data to memory from [DBGDTRRXint](#).
- An LDC to read data from memory to [DBGDTRTXint](#).

See [ISS encoding for an exception from an LDC or STC instruction](#).

EC == 000111

Access to Advanced SIMD or floating-point functionality trapped by a [HCPTR](#). {TASE, TCP10} control.

Excludes exceptions generated because Advanced SIMD and floating-point are not implemented. These are reported with EC value `0b000000`.

See [ISS encoding for an exception from an access to SIMD or floating-point functionality, resulting from HCPTR](#).

EC == 001000

Trapped VMRS access, from ID group trap, that is not reported using EC `0b000111`.

See [ISS encoding for an exception from an MCR or MRC access](#).

EC == 001100

Trapped MRRC access with (coproc==1110).

See [ISS encoding for an exception from an MCRR or MRRC access](#).

EC == 001110

Illegal exception return to AArch32 state.

See [ISS encoding for an exception from an Illegal state or PC alignment fault](#).

EC == 010001

Exception on SVC instruction execution in AArch32 state routed to EL2.

See [ISS encoding for an exception from HVC or SVC instruction execution](#).

EC == 010010

HVC instruction execution in AArch32 state, when HVC is not disabled.

See [ISS encoding for an exception from HVC or SVC instruction execution](#).

EC == 010011

Trapped execution of SMC instruction in AArch32 state.

See [ISS encoding for an exception from SMC instruction execution](#).

EC == 100000

Prefetch Abort from a lower Exception level.

See [ISS encoding for an exception from a Prefetch Abort](#).

EC == 100001

Prefetch Abort taken without a change in Exception level.

See [ISS encoding for an exception from a Prefetch Abort](#).

EC == 100010

PC alignment fault exception.

See [ISS encoding for an exception from an Illegal state or PC alignment fault](#).

EC == 100100

Data Abort from a lower Exception level.

See [ISS encoding for an exception from a Data Abort](#).

EC == 100101

Data Abort taken without a change in Exception level.

See [ISS encoding for an exception from a Data Abort](#).

All other EC values are reserved by ARM, and:

- Unused values in the range `0b000000 - 0b101100` (`0x00 - 0x2C`) are reserved for future use for synchronous exceptions.

- Unused values in the range 0b101101 - 0b111111 (0x2D - 0x3F) are reserved for future use, and might be used for synchronous or asynchronous exceptions.

The effect of programming this field to a reserved value is that behavior is CONstrained UNPREDICTABLE, as described in *Reserved values in System and memory-mapped registers and translation table entries* on page K1-6133.

IL, bit [25]

Instruction length bit. Indicates the size of the instruction that has been trapped to Hyp mode. When this bit is valid, possible values of this bit are:

- 0 16-bit instruction trapped.
- 1 32-bit instruction trapped.

This field is RES1 and not valid for the following cases:

- When the EC field is 0b000000, indicating an exception with an unknown reason.
- Prefetch Aborts.
- Data Aborts for which the HSR.ISS.ISV field is 0.
- When the EC value is 0b001110, indicating an Illegal state exception.

———— Note ————

This is a change from the behavior in ARMv7, where the IL field is UNK/SBZP for the corresponding cases.

The IL field is not valid and is UNKNOWN on an exception from a PC alignment fault.

ISS, bits [24:0]

Instruction Specific Syndrome. Architecturally, this field can be defined independently for each defined Exception class. However, in practice, some ISS encodings are used for more than one Exception class.

The following subsections describe each ISS format.

ISS encoding for exceptions with an unknown reason

This encoding is used by:

- Unknown reason.

The ISS encoding for these exceptions is:

Bits [24:0]

Reserved, RES0.

This EC code is used for all exceptions that are not covered by any other EC value. This includes exceptions that are generated in the following situations:

- The attempted execution of an instruction bit pattern that has no allocated instruction in the current PE mode in the current Security state, including:
 - A read access using a System register encoding pattern that is not allocated for reads at the current Exception level and Security state.
 - A write access using a System register encoding pattern that is not allocated for writes at the current Exception level and Security state.
 - Instruction encodings for instructions not implemented in the implementation.

- In Debug state, the attempted execution of an instruction bit pattern that is unallocated in Debug state.
- In Non-debug state, the attempted execution of an instruction bit pattern that is unallocated in Non-debug state.
- The attempted execution of a short vector floating-point instruction.
- In an implementation that does not include Advanced SIMD and floating-point functionality, an attempted access to Advanced SIMD or floating-point functionality under conditions where that access would be permitted if that functionality was present. This includes the attempted execution of an Advanced SIMD or floating-point instruction, and attempted accesses to Advanced SIMD and floating-point System registers.
- An exception generated because of the value of one of the `SCTLR`.{ITD, SED, CP15BEN} control bits.
- Attempted execution of:
 - An HVC instruction when disabled by `HCR.HCD`, `SCR.HCE`, or `SCR_EL3.HCE`.
 - An SMC instruction when disabled by `SCR.SCD` or `SCR_EL3.SMD`.
 - An HLT instruction when disabled by `EDSCR.HDE`.
- An exception generated because of the attempted execution of an MSR (Banked register) or MRS (Banked register) instruction that would access a Banked register that is not accessible from the Security state and PE mode at which the instruction was executed.

———— **Note** —————

An exception is generated only if the CONSTRAINED UNPREDICTABLE behavior of the instruction is that it is UNDEFINED, see *MSR/MRS Banked registers on page K1-6117*.

- Attempted execution, in Debug state, of:
 - A DCPS1 instruction in Non-secure state from EL0 when EL2 is using AArch32 and the value of `HCR.TGE` is 1.
 - A DCPS2 instruction at EL1 or EL0 when EL2 is not implemented, or when EL3 is using AArch32 and the value of `SCR.NS` is 0, or when EL3 is using AArch64 and the value of `SCR_EL3.NS` is 0.
 - A DCPS3 instruction when EL3 is not implemented, or when the value of `EDSCR.SDD` is 1.
- In Debug state when the value of `EDSCR.SDD` is 1, the attempted execution at EL2, EL1, or EL0 of an instruction that is configured to trap to EL3.

Undefined Instruction exception, when the value of `HCR.TGE` is 1 on page G1-4357 describes the configuration settings for a trap that returns an `HSR.EC` value of `0b000000`.

ISS encoding for an exception from a WFI or WFE instruction

This encoding is used by:

- Trapped WFI or WFE instruction execution.
Conditional WFE and WFI instructions that fail their condition code check do not cause an exception.

The ISS encoding for these exceptions is:

CV, bit [24]

Condition code valid. Possible values of this bit are:

- 0 The COND field is not valid.
- 1 The COND field is valid.

When an A32 instruction is trapped, CV is set to 1.

When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

COND, bits [23:20]

The condition code for the trapped instruction.

When an A32 instruction is trapped, CV is set to 1 and:

- If the instruction is conditional, COND is set to the condition code field value from the instruction.
- If the instruction is unconditional, COND is set to 0b1110.

A conditional A32 instruction that is known to pass its condition code check can be presented either:

- With COND set to 0b1110, the value for unconditional.
- With the COND value held in the instruction.

When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:

- CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
- CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

Bits [19:1]

Reserved, RES0.

TI, bit [0]

Trapped instruction. Possible values of this bit are:

- 0 WFI trapped.
- 1 WFE trapped.

[Traps to Hyp mode of Non-secure EL0 and EL1 execution of WFE and WFI instructions on page G1-4437](#) describes the configuration settings for this trap.

ISS encoding for an exception from an MCR or MRC access

This encoding is used by:

- Trapped MCR or MRC access with (coproc==1111) that is not reported using EC 0b000000.
- Trapped MCR or MRC access with (coproc==1110).

- Trapped VMRS access, from ID group trap, that is not reported using EC 0b000111.

The ISS encoding for these exceptions is:

CV, bit [24]

Condition code valid. Possible values of this bit are:

- 0 The COND field is not valid.
- 1 The COND field is valid.

When an A32 instruction is trapped, CV is set to 1.

When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

COND, bits [23:20]

The condition code for the trapped instruction.

When an A32 instruction is trapped, CV is set to 1 and:

- If the instruction is conditional, COND is set to the condition code field value from the instruction.
- If the instruction is unconditional, COND is set to 0b1110.

A conditional A32 instruction that is known to pass its condition code check can be presented either:

- With COND set to 0b1110, the value for unconditional.
- With the COND value held in the instruction.

When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:

- CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
- CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

Opc2, bits [19:17]

The Opc2 value from the issued instruction.

For a trapped VMRS access, holds the value 0b000.

Opc1, bits [16:14]

The Opc1 value from the issued instruction.

For a trapped VMRS access, holds the value 0b111.

CRn, bits [13:10]

The CRn value from the issued instruction.

For a trapped VMRS access, holds the reg field from the VMRS instruction encoding.

Bit [9]

Reserved, RES0.

Rt, bits [8:5]

The Rt value from the issued instruction, the general-purpose register used for the transfer.

CRm, bits [4:1]

The CRm value from the issued instruction.

For a trapped VMRS access, holds the value 0b0000.

Direction, bit [0]

Indicates the direction of the trapped instruction. The possible values of this bit are:

- | | |
|---|---|
| 0 | Write to System register space. MCR instruction. |
| 1 | Read from System register space. MRC or VMRS instruction. |

The following sections describe configuration settings for traps that are reported using EC value 0b000011:

- [Traps to Hyp mode of Non-secure EL0 and EL1 accesses to the ID registers on page G1-4434.](#)
- [Traps to Hyp mode of Non-secure EL0 and EL1 accesses to lockdown, DMA, and TCM operations on page G1-4433.](#)
- [Traps to Hyp mode of Non-secure EL1 execution of cache maintenance instructions on page G1-4432.](#)
- [Traps to Hyp mode of Non-secure EL1 execution of TLB maintenance instructions on page G1-4431.](#)
- [Traps to Hyp mode of Non-secure EL1 accesses to the Auxiliary Control Register on page G1-4432.](#)
- [Traps to Hyp mode of Non-secure EL0 and EL1 accesses to Performance Monitors registers on page G1-4444.](#)
- [Traps to Hyp mode of Non-secure EL1 accesses to the CPACR on page G1-4439.](#)
- [Traps to Hyp mode of Non-secure EL1 accesses to virtual memory control registers on page G1-4430.](#)
- [General trapping to Hyp mode of Non-secure EL0 and EL1 accesses to System registers in the \(coproc==0b1111\) encoding space on page G1-4440.](#)

The following sections describe configuration settings for traps that are reported using EC value 0b000101:

- [ID group 0, Primary device identification registers on page G1-4435.](#)
- [Traps to Hyp mode of Non-secure System register accesses to trace registers on page G1-4439.](#)
- [Trapping Non-secure System register accesses to Debug ROM registers on page G1-4442.](#)
- [Trapping Non-secure System register accesses to powerdown debug registers on page G1-4442.](#)
- [Trapping general Non-secure System register accesses to debug registers on page G1-4443.](#)

The following sections describes configuration settings for traps that are reported using EC value 0b001000:

- [ID group 0, Primary device identification registers on page G1-4435.](#)
- [ID group 3, Detailed feature identification registers on page G1-4436.](#)

ISS encoding for an exception from an MCRR or MRRC access

This encoding is used by:

- Trapped MCRR or MRRC access with (coproc==1111) that is not reported using EC 0b000000.
- Trapped MRRC access with (coproc==1110).

The ISS encoding for these exceptions is:

CV, bit [24]

Condition code valid. Possible values of this bit are:

- 0 The COND field is not valid.
- 1 The COND field is valid.

When an A32 instruction is trapped, CV is set to 1.

When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

COND, bits [23:20]

The condition code for the trapped instruction.

When an A32 instruction is trapped, CV is set to 1 and:

- If the instruction is conditional, COND is set to the condition code field value from the instruction.
- If the instruction is unconditional, COND is set to 0b1110.

A conditional A32 instruction that is known to pass its condition code check can be presented either:

- With COND set to 0b1110, the value for unconditional.
- With the COND value held in the instruction.

When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:

- CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
- CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

Opc1, bits [19:16]

The Opc1 value from the issued instruction.

Bits [15:14]

Reserved, RES0.

Rt2, bits [13:10]

The Rt2 value from the issued instruction, the second general-purpose register used for the transfer.

Bit [9]

Reserved, RES0.

Rt, bits [8:5]

The Rt value from the issued instruction, the first general-purpose register used for the transfer.

CRm, bits [4:1]

The CRm value from the issued instruction.

Direction, bit [0]

Indicates the direction of the trapped instruction. The possible values of this bit are:

- 0 Write to System register space. MCRR instruction.
- 1 Read from System register space. MRRC instruction.

The following sections describe configuration settings for traps that are reported using EC value 0b000100:

- [Traps to Hyp mode of Non-secure EL1 accesses to virtual memory control registers on page G1-4430.](#)
- [General trapping to Hyp mode of Non-secure EL0 and EL1 accesses to System registers in the \(coproc == 0b1111\) encoding space on page G1-4440.](#)

The following sections describe configuration settings for traps that are reported using EC value 0b001100:

- [Traps to Hyp mode of Non-secure System register accesses to trace registers on page G1-4439.](#)
- [Trapping Non-secure System register accesses to Debug ROM registers on page G1-4442.](#)

ISS encoding for an exception from an LDC or STC instruction

This encoding is used by:

- Trapped LDC or STC access.
The only architected uses of these instructions are:
 - An STC to write data to memory from [DBGDTRRXint](#).
 - An LDC to read data from memory to [DBGDTRTXint](#).

The ISS encoding for these exceptions is:

CV, bit [24]

Condition code valid. Possible values of this bit are:

- 0 The COND field is not valid.
- 1 The COND field is valid.

When an A32 instruction is trapped, CV is set to 1.

When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

COND, bits [23:20]

The condition code for the trapped instruction.

When an A32 instruction is trapped, CV is set to 1 and:

- If the instruction is conditional, COND is set to the condition code field value from the instruction.
- If the instruction is unconditional, COND is set to 0b1110.

A conditional A32 instruction that is known to pass its condition code check can be presented either:

- With COND set to 0b1110, the value for unconditional.

- With the COND value held in the instruction.

When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:

- CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
- CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

imm8, bits [19:12]

The immediate value from the issued instruction.

Bits [11:9]

Reserved, RES0.

Rn, bits [8:5]

The Rn value from the issued instruction. Valid only when AM[2] is 0, indicating an immediate form of the LDC or STC instruction.

When AM[2] is 1, indicating a literal form of the LDC or STC instruction, this field is UNKNOWN.

Offset, bit [4]

Indicates whether the offset is added or subtracted:

- | | |
|---|------------------|
| 0 | Subtract offset. |
| 1 | Add offset. |

This bit corresponds to the U bit in the instruction encoding.

AM, bits [3:1]

Addressing mode. The permitted values of this field are:

- | | |
|-----|---|
| 000 | Immediate unindexed. |
| 001 | Immediate post-indexed. |
| 010 | Immediate offset. |
| 011 | Immediate pre-indexed. |
| 100 | Literal unindexed.
LDC instruction in A32 instruction set only.
For a trapped STC instruction or a trapped T32 LDC instruction this encoding is reserved. |
| 110 | Literal offset.
LDC instruction only.
For a trapped STC instruction, this encoding is reserved. |

The values 0b101 and 0b111 are reserved. The effect of programming this field to a reserved value is that behavior is CONSTRAINED UNPREDICTABLE, as described in [Reserved values in System and memory-mapped registers and translation table entries on page K1-6117](#).

Bit [2] in this subfield indicates the instruction form, immediate or literal.

Bits [1:0] in this subfield correspond to the bits {P, W} in the instruction encoding.

Direction, bit [0]

Indicates the direction of the trapped instruction. The possible values of this bit are:

- | | |
|---|------------------------------------|
| 0 | Write to memory. STC instruction. |
| 1 | Read from memory. LDC instruction. |

[Trapping general Non-secure System register accesses to debug registers on page G1-4443](#) describes the configuration settings for the trap that is reported using EC value 0b000110.

ISS encoding for an exception from an access to SIMD or floating-point functionality, resulting from HCPTR

This encoding is used by:

- Access to Advanced SIMD or floating-point functionality trapped by a HCPTR. {TASE, TCP10} control. Excludes exceptions generated because Advanced SIMD and floating-point are not implemented. These are reported with EC value 0b000000.

The ISS encoding for these exceptions is:

Excludes exceptions that occur because Advanced SIMD and floating-point functionality is not implemented, or because the value of HCR.TGE or HCR_EL2.TGE is 1. These are reported with EC value 0b000000.

CV, bit [24]

Condition code valid. Possible values of this bit are:

- 0 The COND field is not valid.
- 1 The COND field is valid.

When an A32 instruction is trapped, CV is set to 1.

When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

COND, bits [23:20]

The condition code for the trapped instruction.

When an A32 instruction is trapped, CV is set to 1 and:

- If the instruction is conditional, COND is set to the condition code field value from the instruction.
- If the instruction is unconditional, COND is set to 0b1110.

A conditional A32 instruction that is known to pass its condition code check can be presented either:

- With COND set to 0b1110, the value for unconditional.
- With the COND value held in the instruction.

When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:

- CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
- CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

Bits [19:6]

Reserved, RES0.

TA, bit [5]

Indicates trapped use of Advanced SIMD functionality. The possible values of this bit are:

- 0 Exception was not caused by trapped use of Advanced SIMD functionality.
- 1 Exception was caused by trapped use of Advanced SIMD functionality.

Any use of an Advanced SIMD instruction that is not also a floating-point instruction that is trapped to Hyp mode because of a trap configured in the **HCPTR** sets this bit to 1.

For a list of these instructions, see *Controls of Advanced SIMD operation that do not apply to floating-point operation* on page E1-2746.

Bit [4]

Reserved, RES0.

coproc, bits [3:0]

When the TA field returns the value 1, this field returns the value 1010, otherwise this field is RES0.

The following sections describe the configuration settings for the traps that are reported using EC value 0b000111:

- *General trapping to Hyp mode of Non-secure accesses to the SIMD and floating-point registers* on page G1-4437.
- *Traps to Hyp mode of Non-secure accesses to Advanced SIMD functionality* on page G1-4438.

ISS encoding for an exception from HVC or SVC instruction execution

This encoding is used by:

- Exception on SVC instruction execution in AArch32 state routed to EL2.
- HVC instruction execution in AArch32 state, when HVC is not disabled.

The ISS encoding for these exceptions is:

Bits [24:16]

Reserved, RES0.

imm16, bits [15:0]

The value of the immediate field from the HVC or SVC instruction.

For an HVC instruction, this is the value of the imm16 field of the issued instruction.

For an SVC instruction:

- If the instruction is unconditional, then:
 - For the T32 instruction, this field is zero-extended from the imm8 field of the instruction.
 - For the A32 instruction, this field is the bottom 16 bits of the imm24 field of the instruction.
- If the instruction is conditional, this field is UNKNOWN.

The HVC instruction is unconditional, and a conditional SVC instruction generates an exception only if it passes its condition code check. Therefore, the syndrome information for these exceptions does not require conditionality information.

Supervisor Call exception, when the value of HCR.TGE is 1 on page G1-4357 describes the configuration settings for the trap reported with EC value 0b010001.

ISS encoding for an exception from SMC instruction execution

This encoding is used by:

- Trapped execution of SMC instruction in AArch32 state.

The ISS encoding for these exceptions is:

CV, bit [24]

Condition code valid. Possible values of this bit are:

- 0 The COND field is not valid.
- 1 The COND field is valid.

When an A32 instruction is trapped, CV is set to 1.

When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

This field is only valid if CCKNOWNPASS is 1, otherwise it is RES0.

COND, bits [23:20]

The condition code for the trapped instruction.

When an A32 instruction is trapped, CV is set to 1 and:

- If the instruction is conditional, COND is set to the condition code field value from the instruction.
- If the instruction is unconditional, COND is set to 0b1110.

A conditional A32 instruction that is known to pass its condition code check can be presented either:

- With COND set to 0b1110, the value for unconditional.
- With the COND value held in the instruction.

When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:

- CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
- CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

This field is only valid if CCKNOWNPASS is 1, otherwise it is RES0.

CCKNOWNPASS, bit [19]

Indicates whether the instruction might have failed its condition code check.

- 0 The instruction was unconditional, or was conditional and passed its condition code check.
- 1 The instruction was conditional, and might have failed its condition code check.

Bits [18:0]

Reserved, RES0.

[Traps to Hyp mode of Non-secure EL1 execution of SMC instructions on page G1-4434](#) describes the configuration settings for this trap, for instructions executed in Non-secure PL1 modes.

ISS encoding for an exception from a Prefetch Abort

This encoding is used by:

- Prefetch Abort from a lower Exception level.
- Prefetch Abort taken without a change in Exception level.

The ISS encoding for these exceptions is:

Bits [24:11]

Reserved, RES0.

FnV, bit [10]

FAR not Valid, for a Synchronous external abort other than a Synchronous external abort on a translation table walk.

- 0 HIFAR is valid.
- 1 HIFAR is not valid, and holds an UNKNOWN value.

This field is only valid if the IFSC code is 010000. It is RES0 for all other aborts.

EA, bit [9]

External abort type. This bit can provide an IMPLEMENTATION DEFINED classification of External aborts.

For any abort other than an External abort this bit returns a value of 0.

Bit [8]

Reserved, RES0.

S1PTW, bit [7]

For a stage 2 fault, indicates whether the fault was a stage 2 fault on an access made for a stage 1 translation table walk:

- 0 Fault not on a stage 2 translation for a stage 1 translation table walk.
- 1 Fault on the stage 2 translation of an access for a stage 1 translation table walk.

For any abort other than a stage 2 fault this bit is RES0.

Bit [6]

Reserved, RES0.

IFSC, bits [5:0]

Instruction Fault Status Code. Possible values of this field are:

- 000000 Address size fault, translation table base register
- 000001 Address size fault, level 1

000010	Address size fault, level 2
000011	Address size fault, level 3
000101	Translation fault, level 1
000110	Translation fault, level 2
000111	Translation fault, level 3
001001	Access flag fault, level 1
001010	Access flag fault, level 2
001011	Access flag fault, level 3
001101	Permission fault, level 1
001110	Permission fault, level 2
001111	Permission fault, level 3
010000	Synchronous external abort, not on translation table walk
011000	Synchronous parity or ECC error on memory access, not on translation table walk
010101	Synchronous external abort, on translation table walk, level 1
010110	Synchronous external abort, on translation table walk, level 2
010111	Synchronous external abort, on translation table walk, level 3
011101	Synchronous parity or ECC error on memory access on translation table walk, level 1
011110	Synchronous parity or ECC error on memory access on translation table walk, level 2
011111	Synchronous parity or ECC error on memory access on translation table walk, level 3
100010	Debug exception, only when the EC value is 0b100001
110000	TLB conflict abort

All other values are reserved.

When the RAS Extension is implemented, 011000, 011101, 011110 and 011111 are reserved.

———— **Note** ————

ARMv8.2 requires the implementation of the RAS Extension.

For more information about the lookup level associated with a fault, see [The level associated with MMU faults on a Long-descriptor translation table lookup on page G4-4671](#).

The following sections describe cases where Prefetch Abort exceptions can be routed to Hyp mode, generating exceptions that are reported in the HSR with EC value 0b100000:

- [Abort exceptions, when the value of HCR.TGE is 1 on page G1-4357](#).
- [Routing debug exceptions to EL2 using AArch32 on page G1-4358](#).

ISS encoding for an exception from an Illegal state or PC alignment fault

This encoding is used by:

- Illegal exception return to AArch32 state.
- PC alignment fault exception.

The ISS encoding for these exceptions is:

Bits [24:0]

Reserved, RES0.

For more information about the Illegal state exception, see:

- [Illegal changes to PSTATE.M](#) on page G1-4336.
- [Illegal return events from AArch32 state](#) on page G1-4361.
- [Legal returns that set PSTATE.IL to 1](#) on page G1-4363.
- [The Illegal Execution state exception](#) on page G1-4363.

For more information about the PC alignment fault exception, see [Branching to an unaligned PC](#) on page K1-6098.

ISS encoding for an exception from a Data Abort

This encoding is used by:

- Data Abort from a lower Exception level.
- Data Abort taken without a change in Exception level.

The ISS encoding for these exceptions is:

ISV, bit [24]

Instruction syndrome valid. Indicates whether the syndrome information in ISS[23:14] is valid.

0 No valid instruction syndrome. ISS[23:14] are RES0.

1 ISS[23:14] hold a valid instruction syndrome.

This bit is 0 for all faults except Data Aborts generated by stage 2 address translations for which all the following apply to the instruction that generated the Data Abort exception:

- The instruction is an LDR, LDA, LDRT, LDRSH, LDRSHT, LDRH, LDAH, LDRHT, LDRSB, LDRSBT, LDRB, LDAB, LDRBT, STR, STL, STRT, STRH, STLH, STRHT, STRB, STLB, or STRBT instruction.
- The instruction is not performing register writeback.
- The instruction is not using the PC as a source or destination register.

For these cases, ISV is UNKNOWN if the exception was generated in Debug state in memory access mode, as described in [Data Aborts in Memory access mode](#) on page H4-5504, and otherwise indicates whether ISS[23:14] hold a valid syndrome.

———— **Note** ————

In the A32 instruction set, LDR*T and STR*T instructions always perform register writeback and therefore never return a valid instruction syndrome.

When the RAS Extension is implemented, ISV is 0 for any Synchronous external abort.

ISV is set to 0 on a stage 2 abort on a stage 1 translation table walk.

When the RAS Extension is not implemented, it is IMPLEMENTATION DEFINED whether ISV is set to 1 or 0 on a Synchronous external abort on stage 2 translation table walk.

SAS, bits [23:22]

Syndrome Access Size. When ISV is 1, indicates the size of the access attempted by the faulting operation.

00	Byte
01	Halfword
10	Word
11	Doubleword

This field is UNKNOWN when the value of ISV is UNKNOWN.

This field is RES0 when the value of ISV is 0.

SSE, bit [21]

Syndrome Sign Extend. When ISV is 1, for a byte, halfword, or word load operation, indicates whether the data item must be sign extended. For these cases, the possible values of this bit are:

0	Sign-extension not required.
1	Data item must be sign-extended.

For all other operations this bit is 0.

This field is UNKNOWN when the value of ISV is UNKNOWN.

This field is RES0 when the value of ISV is 0.

Bit [20]

Reserved, RES0.

SRT, bits [19:16]

Syndrome Register transfer. When ISV is 1, the register number of the Rt operand of the faulting instruction.

This field is UNKNOWN when the value of ISV is UNKNOWN.

This field is RES0 when the value of ISV is 0.

Bit [15]

Reserved, RES0.

AR, bit [14]

Acquire/Release. When ISV is 1, the possible values of this bit are:

0	Instruction did not have acquire/release semantics.
1	Instruction did have acquire/release semantics.

This field is UNKNOWN when the value of ISV is UNKNOWN.

This field is RES0 when the value of ISV is 0.

Bits [13:12]

Reserved, RES0.

AET, bit [11:10]

Asynchronous Error Type.

When the RAS Extension is implemented and the value returned in the DFSC field is 010001, describes the state of the PE after taking the SError interrupt exception. The possible values of this field are:

00	Uncontainable error (UC) or uncategorized.
01	Unrecoverable error (UEU).
10	Restartable error (UEO) or Corrected error (CE).
11	Recoverable error (UER).

On a synchronous Data Abort, this field is RES0.

If multiple errors are taken as a single SError interrupt exception, the overall state of the PE is reported. For example, if both a Recoverable and Unrecoverable error occurred, the state is Unrecoverable.

———— Note —————

Software can use this information to determine what recovery might be possible. The recovery software must also examine any implemented fault records to determine the location and extent of the error.

When RAS Extension is not implemented, or when DFSC is not 010001:

- Bit[11] is RES0.
- Bit[10] forms the FnV field.

———— Note —————

ARMv8.2 requires the implementation of the RAS Extension.

FnV, bit [10]

FAR not Valid, for a Synchronous external abort other than a Synchronous external abort on a translation table walk.

0	HDFAR is valid.
1	HDFAR is not valid, and holds an UNKNOWN value.

When the RAS Extension is not implemented, this field is valid only if DFSC is 010000. It is RES0 for all other aborts.

When the RAS Extension is implemented:

- If DFSC is 010000, this field is valid.
- If DFSC is 010001, this bit forms part of the AET field.
- This field is RES0 for all other aborts.

———— Note —————

ARMv8.2 requires the implementation of the RAS Extension.

EA, bit [9]

External abort type. This bit can provide an IMPLEMENTATION DEFINED classification of External aborts.

For any abort other than an External abort this bit returns a value of 0.

CM, bit [8]

Cache maintenance. For a synchronous fault, identifies fault that comes from a cache maintenance or address translation instruction. For synchronous faults, the possible values of this bit are:

0	Fault not generated by a cache maintenance or address translation instruction.
---	--

1 Fault generated by a cache maintenance or address translation instruction.

For an asynchronous Data Abort exception, this bit is 0.

S1PTW, bit [7]

For a stage 2 fault, indicates whether the fault was a stage 2 fault on an access made for a stage 1 translation table walk:

0 Fault not on a stage 2 translation for a stage 1 translation table walk.

1 Fault on the stage 2 translation of an access for a stage 1 translation table walk.

For any abort other than a stage 2 fault this bit is RES0.

———— Note —————

ARMv8.2 requires the implementation of the RAS Extension.

WnR, bit [6]

Write not Read. Indicates whether a synchronous abort was caused by a write instruction or a read instruction. The possible values of this bit are:

0 Abort caused by a read instruction.

1 Abort caused by a write instruction.

For faults on cache maintenance and address translation instructions, this bit always returns a value of 1.

On an asynchronous Data Abort:

- When the RAS Extension is not implemented this bit is UNKNOWN.
- When the RAS Extension is implemented this bit is RES0.

———— Note —————

ARMv8.2 requires the implementation of the RAS Extension.

DFSC, bits [5:0]

Data Fault Status Code. Possible values of this field are:

000000 Address size fault, translation table base register

000001 Address size fault, level 1

000010 Address size fault, level 2

000011 Address size fault, level 3

000101 Translation fault, level 1

000110 Translation fault, level 2

000111 Translation fault, level 3

001001 Access flag fault, level 1

001010 Access flag fault, level 2

001011 Access flag fault, level 3

001101 Permission fault, level 1

001110 Permission fault, level 2

001111 Permission fault, level 3

010000 Synchronous external abort, not on translation table walk

011000 Synchronous parity or ECC error on memory access, not on translation table walk

010001 SError interrupt

011001 SError interrupt from a parity or ECC error on memory access

010101 Synchronous external abort, on translation table walk, level 1

010110	Synchronous external abort, on translation table walk, level 2
010111	Synchronous external abort, on translation table walk, level 3
011101	Synchronous parity or ECC error on memory access on translation table walk, level 1
011110	Synchronous parity or ECC error on memory access on translation table walk, level 2
011111	Synchronous parity or ECC error on memory access on translation table walk, level 3
100001	Alignment fault
100010	Debug exception, only when the EC value is 0b100100
110000	TLB conflict abort
110100	IMPLEMENTATION DEFINED fault (Lockdown fault)
110101	IMPLEMENTATION DEFINED fault (Unsupported Exclusive access fault)

All other values are reserved.

When the RAS Extension is implemented, 011000, 011001, 011101, 011110, and 011111 are reserved.

For more information about the lookup level associated with a fault, see [The level associated with MMU faults on a Long-descriptor translation table lookup on page G4-4671](#).

The following describe cases where Data Abort exceptions can be routed to Hyp mode, generating exceptions that are reported in the HSR with EC value 0b100100:

- [Abort exceptions, when the value of HCR.TGE is 1 on page G1-4357](#).
- [Routing debug exceptions to EL2 using AArch32 on page G1-4358](#).

The following describe cases that can cause a Data Abort exception that is taken to Hyp mode, and reported in the HSR with EC value of 0b100000 or 0b100100:

- [Hyp mode control of Non-secure access permissions on page G4-4614](#).
- [Memory fault reporting in Hyp mode on page G4-4675](#).

Accessing the HSR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 4, <Rt>, c5, c2, 0	100	000	0101	1111	0010

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	-
x	0	1	-	-	RW	RW
x	1	1	-	n/a	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state](#) on page G1-4344 for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64](#) on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 0)$:
 - If $HSTR_EL2.T5 == 1$, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 1) \ \&\& \ (HCR_EL2.TGE == 0)$:
 - If $HSTR_EL2.T5 == 1$, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $HSTR.T5 == 1$, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

G6.2.70 HSTR, Hyp System Trap Register

The HSTR characteristics are:

Purpose

Controls trapping to Hyp mode of Non-secure accesses, at EL1 or lower, to the System register in the coproc == 1111 encoding space, by the CRn value used to access the register using MCR or MRC instruction. When the register is accessible using an MCRR or MRRC instruction, this is the CRm value used to access the register.

Configurations

AArch32 System register HSTR is architecturally mapped to AArch64 System register [HSTR_EL2](#).

If EL2 is not implemented, this register is RES0 from EL3.

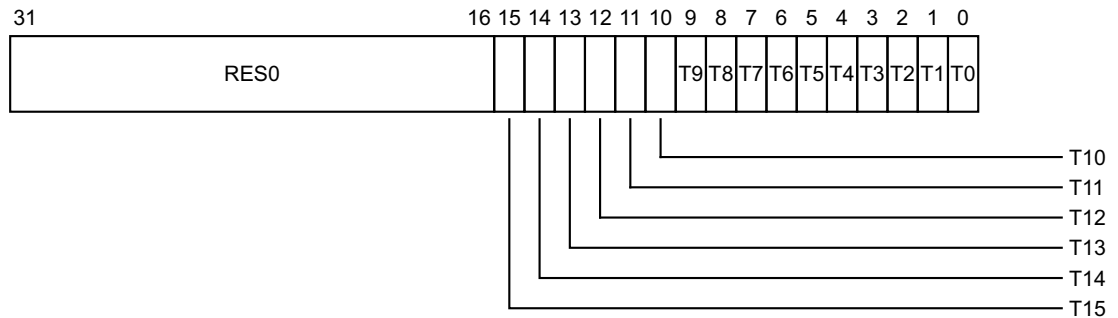

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into EL2 with EL2 using AArch32, or into EL3 with EL3 using AArch32. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

Attributes

HSTR is a 32-bit register.

Field descriptions

The HSTR bit assignments are:

Bits [31:16]

Reserved, RES0.

T<n>, bit [n], for n = 0 to 15

Fields T14 and T4 are RES0.

The remaining fields control whether Non-secure EL0 and EL1 accesses, using MCR, MRC, MCRR, and MRRC instructions, to the System registers in the coproc == 1111 encoding space are trapped to Hyp mode:

- 0 This control has no effect on Non-secure EL0 or EL1 accesses to System registers.
- 1 Any Non-secure EL1 MCR, MRC access with coproc == 1111 and CRn == <n> is trapped to Hyp mode if the access is not UNDEFINED when the value of this field is 0.
Any Non-secure EL1 MCRR, MRRC access with coproc == 1111 and CRm == <n> is trapped to Hyp mode if the access is not UNDEFINED when the value of this field is 0.

For example, when HSTR.T7 is 1:

- Any 32-bit access from a Non-secure EL1 mode, using an MCR or MRC instruction with coproc set to 1111 and <CRn> set to c7, and that is not UNDEFINED when HSTR.T7 is 0, is trapped to Hyp mode.

- Any 64-bit access from a Non-secure EL1 mode, using an MCRR or MRRC instruction with coproc set to 1111 and <CRm> set to c7, and that is not UNDEFINED when HSTR.T7 is 0, is trapped to Hyp mode.

When this register has an architecturally-defined reset value, this field resets to 0.

Accessing the HSTR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 4, <Rt>, c1, c1, 3	100	011	0001	1111	0001

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	-
x	0	1	-	-	RW	RW
x	1	1	-	n/a	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If HSTR_EL2.T1==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If HSTR_EL2.T1==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HSTR.T1==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

G6.2.71 HTCR, Hyp Translation Control Register

The HTCR characteristics are:

Purpose

The control register for stage 1 of the EL2 translation regime.

Note

This stage of translation always uses the Long-descriptor translation table format.

Configurations

AArch32 System register HTCR is architecturally mapped to AArch64 System register [TCR_EL2](#).

If EL2 is not implemented, this register is RES0 from EL3.

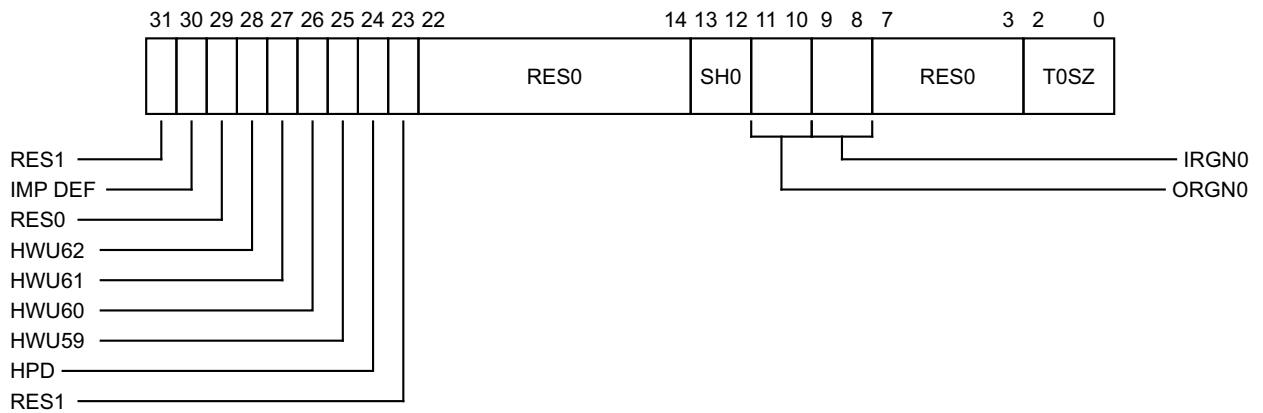

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

HTCR is a 32-bit register.

Field descriptions

The HTCR bit assignments are:

Bit [31]

Reserved, RES1.

IMP DEF, bit [30]

IMPLEMENTATION DEFINED.

Bit [29]

Reserved, RES0.

HWU62, bit [28]

In ARMv8.2

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[62] of the stage 1 translation table block or level 3 entry if the HTCR.HPD value is 1.

Defined values are:

- 0 The stage 1 translation table entry block or level 3 bit cannot be interpreted by hardware for an IMPLEMENTATION DEFINED purpose.

- 1 The stage 1 translation table entry block or level 3 bit can be interpreted by hardware for an IMPLEMENTATION DEFINED purpose if the HTCR.HPD value is 1.

This bit is RES0 if [ARMv8.2-TTPBHA](#) is not implemented.

In ARMv8.1 and ARMv8.0.

Reserved, RES0.

HWU61, bit [27]

In ARMv8.2

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[61] of the stage 1 translation table block or level 3 entry if the HTCR.HPD value is 1.

Defined values are:

- 0 The stage 1 translation table entry block or level 3 bit cannot be interpreted by hardware for an IMPLEMENTATION DEFINED purpose.
- 1 The stage 1 translation table entry block or level 3 bit can be interpreted by hardware for an IMPLEMENTATION DEFINED purpose if HTCR.HPD bit value is 1.

This bit is RES0 if [ARMv8.2-TTPBHA](#) is not implemented.

In ARMv8.1 and ARMv8.0.

Reserved, RES0.

HWU60, bit [26]

In ARMv8.2

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[60] of the stage 1 translation table block or level 3 entry.

Defined values are:

- 0 The stage 1 translation table entry block or level 3 bit cannot be interpreted by hardware for an IMPLEMENTATION DEFINED purpose.
- 1 The stage 1 translation table entry block or level 3 bit can be interpreted by hardware for an IMPLEMENTATION DEFINED purpose if the HTCR.HPD bit value is 1.

This bit is RES0 if [ARMv8.2-TTPBHA](#) is not implemented.

In ARMv8.1 and ARMv8.0.

Reserved, RES0.

HWU59, bit [25]

In ARMv8.2

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[59] of the stage 1 translation table block or level 3 entry.

Defined values are:

- 0 The stage 1 translation table entry block or level 3 bit cannot be interpreted by hardware for an IMPLEMENTATION DEFINED purpose.
- 1 The stage 1 translation table entry block or level 3 bit can be interpreted by hardware for an IMPLEMENTATION DEFINED purpose if the HTCR.HPD bit value is 1.

This bit is RES0 if [ARMv8.2-TTPBHA](#) is not implemented.

In ARMv8.1 and ARMv8.0.

Reserved, RES0.

HPD, bit [24]

In ARMv8.2

Hierarchical Permission Disables. This affects the hierarchical control bits, APTable, XNTable, and PXNTable, in the PL2 translation regime.

Defined values are:

- 0 Hierarchical permissions are enabled.
- 1 Hierarchical permissions are disabled.

When disabled, the permissions are treated as if the bits are zero.

This bit is RES0 if [ARMv8.2-AA32HPD](#) is not implemented.

In ARMv8.1 and ARMv8.0.

Reserved, RES0.

Bit [23]

Reserved, RES1.

Bits [22:14]

Reserved, RES0.

SH0, bits [13:12]

Shareability attribute for memory associated with translation table walks using [HTTBR](#).

- 00 Non-shareable
- 10 Outer Shareable
- 11 Inner Shareable

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is CONstrained UNPREDICTABLE, as described in [Reserved values in System and memory-mapped registers and translation table entries on page K1-6117](#).

ORGN0, bits [11:10]

Outer cacheability attribute for memory associated with translation table walks using [HTTBR](#).

- 00 Normal memory, Outer Non-cacheable
- 01 Normal memory, Outer Write-Back Read-Allocate Write-Allocate Cacheable
- 10 Normal memory, Outer Write-Through Read-Allocate No Write-Allocate Cacheable
- 11 Normal memory, Outer Write-Back Read-Allocate No Write-Allocate Cacheable

IRGN0, bits [9:8]

Inner cacheability attribute for memory associated with translation table walks using [HTTBR](#).

- 00 Normal memory, Inner Non-cacheable
- 01 Normal memory, Inner Write-Back Read-Allocate Write-Allocate Cacheable
- 10 Normal memory, Inner Write-Through Read-Allocate No Write-Allocate Cacheable
- 11 Normal memory, Inner Write-Back Read-Allocate No Write-Allocate Cacheable

Bits [7:3]

Reserved, RES0.

T0SZ, bits [2:0]

The size offset of the memory region addressed by [HTTBR](#). The region size is $2^{(32-T0SZ)}$ bytes.

Accessing the HTCR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 4, <Rt>, c2, c0, 2	100	010	0010	1111	0000

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	-
x	0	1	-	-	RW	RW
x	1	1	-	n/a	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If HSTR_EL2.T2==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If HSTR_EL2.T2==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HSTR.T2==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

G6.2.72 HTPIDR, Hyp Software Thread ID Register

The HTPIDR characteristics are:

Purpose

Provides a location where software running in Hyp mode can store thread identifying information that is not visible to Non-secure software executing at EL0 or EL1, for hypervisor management purposes.

The PE makes no use of this register.

Configurations

AArch32 System register HTPIDR is architecturally mapped to AArch64 System register [TPIDR_EL2](#)[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

The PE never updates this register. This means the register is always UNKNOWN on reset.

Attributes

HTPIDR is a 32-bit register.

Field descriptions

The HTPIDR bit assignments are:

Bits [31:0]

Thread ID. Thread identifying information stored by software running at this Exception level.

Accessing the HTPIDR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 4, <Rt>, c13, c0, 2	100	010	1101	1111	0000

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	-
x	0	1	-	-	RW	RW
x	1	1	-	n/a	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 0)$:
 - If $HSTR_EL2.T13 == 1$, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 1) \ \&\& \ (HCR_EL2.TGE == 0)$:
 - If $HSTR_EL2.T13 == 1$, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $HSTR.T13 == 1$, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

G6.2.73 HTTBR, Hyp Translation Table Base Register

The HTTBR characteristics are:

Purpose

Holds the base address of the translation table for the initial lookup for stage 1 of an address translation in the EL2 translation regime, and other information for this translation regime.

Configurations

AArch32 System register HTTBR is architecturally mapped to AArch64 System register [TTBR0_EL2](#).

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

HTTBR is a 64-bit register.

Field descriptions

The HTTBR bit assignments are:

Bits [63:48]

Reserved, RES0.

BADDR, bits [47:1]

Translation table base address, bits[47:x], Bits [x-1:1] are RES0, with the additional requirement that if bits[x-1:3] are not all zero, this is a misaligned translation table base address, with effects that are CONstrained UNPREDICTABLE, and must be one of the following:

- Register bits [x-1:3] are treated as if all the bits are zero. The value read back from these bits is either the value written or zero.
- The result of the calculation of an address for a translation table walk using this register can be corrupted in those bits that are nonzero.

x is determined from the value of [HTCR.TOSZ](#) as follows:

- If [HTCR.TOSZ](#) is 0 or 1, $x = 5 - \text{HTCR.TOSZ}$.
- If [HTCR.TOSZ](#) is greater than 1, $x = 14 - \text{HTCR.TOSZ}$.

If bits[47:40] of the translation table base address are not zero, an Address size fault is generated.

CnP, bit [0]

In ARMv8.2

Common not Private. In an implementation that includes [ARMv8.2-TTCNP](#), indicates whether each entry that is pointed to by HTTBR is a member of a common set that can be used by every PE in the Inner Shareable domain for which the value of HTTBR.CnP is 1.

- 0 The translation table entries pointed to by HTTBR are permitted to differ from corresponding entries for HTTBR for other PEs in the Inner Shareable domain. This is not affected by the value of HTTBR.CnP on those other PEs.

- 1 The translation table entries pointed to by HTTBR are the same as the translation table entries pointed to by HTTBR on every other PE in the Inner Shareable domain for which the value of HTTBR.CnP is 1.

Note

If the value of the HTTBR.CnP bit is 1 on multiple PEs in the same Inner Shareable domain and those HTTBRs do not point to the same translation table entries when the other conditions specified for the case when the value of CnP is 1 apply, then the results of translations are *CONSTRAINED UNPREDICTABLE*, see *CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values on page K1-6101*.

In an implementation that does not include [ARMv8.2-TTCNP](#) this field is RES0.

In ARMv8.1 and ARMv8.0.

Reserved, RES0.

Accessing the HTTBR

This register can be read using MRRC with the following syntax:

MRRC <syntax>

This register can be written using MCRR with the following syntax:

MCRR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	coproc	CRm
p15, 4, <Rt>, <Rt2>, c2	0100	1111	0010

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	-
x	0	1	-	-	RW	RW
x	1	1	-	n/a	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344* for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827* for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If `HSTR_EL2.T2==1`, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If `HSTR_EL2.T2==1`, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If [HSTR.T2](#)==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

G6.2.74 HVBAR, Hyp Vector Base Address Register

The HVBAR characteristics are:

Purpose

Holds the vector base address for any exception that is taken to Hyp mode.

Configurations

AArch32 System register HVBAR is architecturally mapped to AArch64 System register [VBAR_EL2](#)[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

HVBAR is a 32-bit register.

Field descriptions

The HVBAR bit assignments are:

Bits [31:5]

Vector Base Address. Bits[31:5] of the base address of the exception vectors for exceptions taken to this Exception level. Bits[4:0] of an exception vector are the exception offset.

Bits [4:0]

Reserved, RES0.

Accessing the HVBAR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 4, <Rt>, c12, c0, 0	100	000	1100	1111	0000

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	-
x	0	1	-	-	RW	RW
x	1	1	-	n/a	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If [HSTR_EL2.T12==1](#), Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If [HSTR_EL2.T12==1](#), Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If [HSTR.T12==1](#), Non-secure accesses to this register from EL1 are trapped to Hyp mode.

G6.2.75 ICIALLU, Instruction Cache Invalidate All to PoU

The ICIALLU characteristics are:

Purpose

Invalidate all instruction caches to PoU. If branch predictors are architecturally visible, also flush branch predictors.

Configurations

AArch32 System instruction ICIALLU performs the same function as AArch64 System instruction [IC IALLU](#).

Attributes

ICIALLU is a 32-bit System instruction.

Field descriptions

ICIALLU ignores the value in the register specified by the instruction. Software does not have to write a value to the register before issuing this instruction.

Executing the ICIALLU instruction

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c7, c5, 0	000	000	0111	1111	0101

The PE ignores the value of <Rt>. Software does not have to write a value to this register before issuing this instruction.

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	WO	n/a	WO
x	0	1	-	WO	WO	WO
x	1	1	-	n/a	WO	WO

When [HCR.FB](#) is 1, at Non-secure EL1 this instruction executes as a [ICIALUIS](#).

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \&\& (HCR_EL2.E2H == 0)$:
 - If $HCR_EL2.TPU == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
 - If $HSTR_EL2.T7 == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \&\& (HCR_EL2.E2H == 1) \&\& (HCR_EL2.TGE == 0)$:
 - If $HCR_EL2.TPU == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
 - If $HSTR_EL2.T7 == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $HCR.TPU == 1$, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
 - If $HSTR.T7 == 1$, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

G6.2.76 ICIALLUIS, Instruction Cache Invalidate All to PoU, Inner Shareable

The ICIALLUIS characteristics are:

Purpose

Invalidate all instruction caches Inner Shareable to PoU. If branch predictors are architecturally visible, also flush branch predictors.

Configurations

AArch32 System instruction ICIALLUIS performs the same function as AArch64 System instruction [IC IALLUIS](#).

Attributes

ICIALLUIS is a 32-bit System instruction.

Field descriptions

ICIALLUIS ignores the value in the register specified by the instruction. Software does not have to write a value to the register before issuing this instruction.

Executing the ICIALLUIS instruction

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c7, c1, 0	000	000	0111	1111	0001

The PE ignores the value of <Rt>. Software does not have to write a value to this register before issuing this instruction.

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	WO	n/a	WO
x	0	1	-	WO	WO	WO
x	1	1	-	n/a	WO	WO

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If HCR_EL2.TPU==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

- If `HSTR_EL2.T7==1`, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and `(SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0)`:
 - If `HCR_EL2.TPU==1`, Non-secure execution of this instruction at EL1 is trapped to EL2.
 - If `HSTR_EL2.T7==1`, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and `SCR_EL3.NS == 1`:
 - If `HCR.TPU==1`, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
 - If `HSTR.T7==1`, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

G6.2.77 ICIMVAU, Instruction Cache line Invalidate by VA to PoU

The ICIMVAU characteristics are:

Purpose

Invalidate instruction cache line by virtual address to PoU.

Configurations

AArch32 System instruction ICIMVAU performs the same function as AArch64 System instruction [IC IVAU](#).

Attributes

ICIMVAU is a 32-bit System instruction.

Field descriptions

The ICIMVAU input value bit assignments are:

Bits [31:0]

Virtual address to use.

Executing the ICIMVAU instruction

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c7, c5, 1	000	001	0111	1111	0101

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	WO	n/a	WO
x	0	1	-	WO	WO	WO
x	1	1	-	n/a	WO	WO

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \&\& (HCR_EL2.E2H == 0)$:
 - If $HCR_EL2.TPU == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
 - If $HSTR_EL2.T7 == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \&\& (HCR_EL2.E2H == 1) \&\& (HCR_EL2.TGE == 0)$:
 - If $HCR_EL2.TPU == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
 - If $HSTR_EL2.T7 == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $HCR.TPU == 1$, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
 - If $HSTR.T7 == 1$, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

G6.2.78 ID_AFR0, Auxiliary Feature Register 0

The ID_AFR0 characteristics are:

Purpose

Provides information about the IMPLEMENTATION DEFINED features of the PE in AArch32 state.

Must be interpreted with the Main ID Register, [MIDR](#).

For general information about the interpretation of the ID registers see [Principles of the ID scheme for fields in ID registers on page G4-4701](#).

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register ID_AFR0 is architecturally mapped to AArch64 System register [ID_AFR0_EL1](#).

Attributes

ID_AFR0 is a 32-bit register.

Field descriptions

The ID_AFR0 bit assignments are:

Bits [31:16]

Reserved, RES0.

IMPLEMENTATION DEFINED, bits [15:12]

IMPLEMENTATION DEFINED.

IMPLEMENTATION DEFINED, bits [11:8]

IMPLEMENTATION DEFINED.

IMPLEMENTATION DEFINED, bits [7:4]

IMPLEMENTATION DEFINED.

IMPLEMENTATION DEFINED, bits [3:0]

IMPLEMENTATION DEFINED.

Accessing the ID_AFR0

This register can be read using MRC with the following syntax:

MRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c0, c1, 3	000	011	0000	1111	0001

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	RO	n/a	RO
x	0	1	-	RO	RO	RO
x	1	1	-	n/a	RO	RO

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If HCR_EL2.TID3==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If HCR_EL2.TID3==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HCR.TID3==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
 - If HSTR.T0==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.

G6.2.79 ID_DFR0, Debug Feature Register 0

The ID_DFR0 characteristics are:

Purpose

Provides top level information about the debug system in AArch32 state.

Must be interpreted with the Main ID Register, [MIDR](#).

For general information about the interpretation of the ID registers see [Principles of the ID scheme for fields in ID registers on page G4-4701](#).

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register ID_DFR0 is architecturally mapped to AArch64 System register [ID_DFR0_EL1](#).

Attributes

ID_DFR0 is a 32-bit register.

Field descriptions

The ID_DFR0 bit assignments are:

31	28 27	24 23	20 19	16 15	12 11	8 7	4 3	0
RES0	PerfMon	MProfDbg	MMapTrc	CopTrc	MMapDbg	CopSDBG	CopDbg	

Bits [31:28]

Reserved, RES0.

PerfMon, bits [27:24]

Performance Monitors. Support for System registers-based ARM Performance Monitors Extension, using registers in the coproc == 1111 encoding space, for A and R profile processors. Defined values are:

0000	Performance Monitors Extension System registers not implemented.
0001	Support for Performance Monitors Extension version 1 (PMUv1) System registers.
0010	Support for Performance Monitors Extension version 2 (PMUv2) System registers.
0011	Support for Performance Monitors Extension version 3 (PMUv3) System registers.
0100	Support for Performance Monitors Extension version 3 (PMUv3) System registers, with a 16-bit evtCount field.
1111	IMPLEMENTATION DEFINED form of Performance Monitors System registers supported. PMUv3 not supported.

All other values are reserved.

In ARMv8.0 the permitted values are 0000, 0011, and 1111.

From ARMv8.1 the permitted values are 0000, 0100, and 1111.

In ARMv7, the value 0000 can mean that PMUv1 is implemented. PMUv1 is not permitted in an ARMv8 implementation.

MProfDbg, bits [23:20]

M Profile Debug. Support for memory-mapped debug model for M profile processors. Defined values are:

0000	Not supported.
------	----------------

0001 Support for M profile Debug architecture, with memory-mapped access.
All other values are reserved.
In ARMv8-A the only permitted value is 0000.

MMapTrc, bits [19:16]

Memory Mapped Trace. Support for memory-mapped trace model. Defined values are:
0000 Not supported.
0001 Support for ARM trace architecture, with memory-mapped access.
All other values are reserved.
In ARMv8-A the permitted values are 0000 and 0001.
In the Trace registers, the ETMIDR gives more information about the implementation.

CopTrc, bits [15:12]

Support for System registers-based trace model, using registers in the coproc == 1110 encoding space. Defined values are:
0000 Not supported.
0001 Support for ARM trace architecture, with System registers access.
All other values are reserved.
In ARMv8-A the permitted values are 0000 and 0001.
In the Trace registers, the ETMIDR gives more information about the implementation.

MMapDbg, bits [11:8]

Memory Mapped Debug. Support for v7 memory-mapped debug model, for A and R profile processors.
In ARMv8-A this field is RES0.
The optional memory map defined by ARMv8 is not compatible with ARMv7.

CopSDBG, bits [7:4]

Support for a System registers-based Secure debug model, using registers in the coproc = 1110 encoding space, for an A profile processor that includes EL3.
If EL3 is not implemented and the implemented Security state is Non-Secure state, this field is RES0.
Otherwise, this field reads the same as bits [3:0].

CopDbg, bits [3:0]

Support for System registers-based debug model, using registers in the coproc == 1110 encoding space, for A and R profile processors. Defined values are:
0000 Not supported.
0010 Support for ARMv6, v6 Debug architecture, with System registers access.
0011 Support for ARMv6, v6.1 Debug architecture, with System registers access.
0100 Support for ARMv7, v7 Debug architecture, with System registers access.
0101 Support for ARMv7, v7.1 Debug architecture, with System registers access.
0110 Support for ARMv8 debug architecture, with System registers access.
0111 Support for ARMv8 debug architecture, with System registers access, and Virtualization Host extensions.
1000 Support for ARMv8.2 debug architecture.
All other values are reserved.
In an ARMv8.0 implementation, the only permitted value is 0b0110.
In an ARMv8.1 implementation that does not include ARMv8.1-VHE, the permitted values are 0b0110 and 0b0111.

In an ARMv8.1 implementation that includes ARMv8.1-VHE, the only permitted value is 0b0111.

In an ARMv8.2 implementation, the only permitted value is 0b1000.

Accessing the ID_DFR0

This register can be read using MRC with the following syntax:

MRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c0, c1, 2	000	010	0000	1111	0001

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	RO	n/a	RO
x	0	1	-	RO	RO	RO
x	1	1	-	n/a	RO	RO

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If HCR_EL2.TID3==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If HCR_EL2.TID3==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HCR.TID3==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
 - If HSTR.T0==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.

G6.2.80 ID_ISAR0, Instruction Set Attribute Register 0

The ID_ISAR0 characteristics are:

Purpose

Provides information about the instruction sets implemented by the PE in AArch32 state.

Must be interpreted with ID_ISAR1, ID_ISAR2, ID_ISAR3, ID_ISAR4, and ID_ISAR5.

For general information about the interpretation of the ID registers see *Principles of the ID scheme for fields in ID registers* on page G4-4701.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register ID_ISAR0 is architecturally mapped to AArch64 System register ID_ISAR0_EL1.

Attributes

ID_ISAR0 is a 32-bit register.

Field descriptions

The ID_ISAR0 bit assignments are:

31	28 27	24 23	20 19	16 15	12 11	8 7	4 3	0
RES0	Divide	Debug	Coprocc	CmpBranch	BitField	BitCount	Swap	

Bits [31:28]

Reserved, RES0.

Divide, bits [27:24]

Indicates the implemented Divide instructions. Defined values are:

0000 None implemented.

0001 Adds SDIV and UDIV in the T32 instruction set.

0010 As for 0001, and adds SDIV and UDIV in the A32 instruction set.

All other values are reserved.

In ARMv8-A the only permitted value is 0010.

Debug, bits [23:20]

Indicates the implemented Debug instructions. Defined values are:

0000 None implemented.

0001 Adds BKPT.

All other values are reserved.

In ARMv8-A the only permitted value is 0001.

Coprocc, bits [19:16]

Indicates the implemented System register access instructions. Defined values are:

0000 None implemented, except for instructions separately attributed by the architecture to provide access to AArch32 System registers and System instructions.

0001 Adds generic CDP, LDC, MCR, MRC, and STC.

0010 As for 0001, and adds generic CDP2, LDC2, MCR2, MRC2, and STC2.

0011 As for 0010, and adds generic MCRR and MRRC.

0100 As for 0011, and adds generic MCRR2 and MRRC2.
All other values are reserved.
In ARMv8-A the only permitted value is 0000.

CmpBranch, bits [15:12]

Indicates the implemented combined Compare and Branch instructions in the T32 instruction set.
Defined values are:
0000 None implemented.
0001 Adds CBNZ and CBZ.
All other values are reserved.
In ARMv8-A the only permitted value is 0001.

BitField, bits [11:8]

Indicates the implemented BitField instructions. Defined values are:
0000 None implemented.
0001 Adds BFC, BFI, SBFX, and UBFX.
All other values are reserved.
In ARMv8-A the only permitted value is 0001.

BitCount, bits [7:4]

Indicates the implemented Bit Counting instructions. Defined values are:
0000 None implemented.
0001 Adds CLZ.
All other values are reserved.
In ARMv8-A the only permitted value is 0001.

Swap, bits [3:0]

Indicates the implemented Swap instructions in the A32 instruction set. Defined values are:
0000 None implemented.
0001 Adds SWP and SWPB.
All other values are reserved.
In ARMv8-A the only permitted value is 0000.

Accessing the ID_ISAR0

This register can be read using MRC with the following syntax:

MRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c0, c2, 0	000	000	0000	1111	0010

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	RO	n/a	RO
x	0	1	-	RO	RO	RO
x	1	1	-	n/a	RO	RO

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If HCR_EL2.TID3==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If HCR_EL2.TID3==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HCR.TID3==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
 - If HSTR.T0==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.

G6.2.81 ID_ISAR1, Instruction Set Attribute Register 1

The ID_ISAR1 characteristics are:

Purpose

Provides information about the instruction sets implemented by the PE in AArch32 state.

Must be interpreted with ID_ISAR0, ID_ISAR2, ID_ISAR3, ID_ISAR4, and ID_ISAR5.

For general information about the interpretation of the ID registers see *Principles of the ID scheme for fields in ID registers* on page G4-4701.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register ID_ISAR1 is architecturally mapped to AArch64 System register ID_ISAR1_EL1.

Attributes

ID_ISAR1 is a 32-bit register.

Field descriptions

The ID_ISAR1 bit assignments are:

31	28 27	24 23	20 19	16 15	12 11	8 7	4 3	0
Jazelle	Interwork	Immediate	IfThen	Extend	Except_AR	Except	Endian	

Jazelle, bits [31:28]

Indicates the implemented Jazelle extension instructions. Defined values are:

0000 No support for Jazelle.

0001 Adds the BXJ instruction, and the J bit in the PSR. This setting might indicate a trivial implementation of the Jazelle extension.

All other values are reserved.

In ARMv8-A the only permitted value is 0001.

Interwork, bits [27:24]

Indicates the implemented Interworking instructions. Defined values are:

0000 None implemented.

0001 Adds the BX instruction, and the T bit in the PSR.

0010 As for 0001, and adds the BLX instruction. PC loads have BX-like behavior.

0011 As for 0010, and guarantees that data-processing instructions in the A32 instruction set with the PC as the destination and the S bit clear have BX-like behavior.

All other values are reserved.

In ARMv8-A the only permitted value is 0011.

Immediate, bits [23:20]

Indicates the implemented data-processing instructions with long immediates. Defined values are:

0000 None implemented.

0001 Adds:

- The MOVT instruction.
- The MOV instruction encodings with zero-extended 16-bit immediates.

- The T32 ADD and SUB instruction encodings with zero-extended 12-bit immediates, and the other ADD, ADR, and SUB encodings cross-referenced by the pseudocode for those encodings.

All other values are reserved.

In ARMv8-A the only permitted value is 0001.

IfThen, bits [19:16]

Indicates the implemented If-Then instructions in the T32 instruction set. Defined values are:

0000 None implemented.

0001 Adds the IT instructions, and the IT bits in the PSRs.

All other values are reserved.

In ARMv8-A the only permitted value is 0001.

Extend, bits [15:12]

Indicates the implemented Extend instructions. Defined values are:

0000 No scalar sign-extend or zero-extend instructions are implemented, where scalar instructions means non-Advanced SIMD instructions.

0001 Adds the SXTB, SXTB16, UXTB, and UXTH instructions.

0010 As for 0001, and adds the SXTB16, SXTAB, SXTAB16, SXTAH, UXTB16, UXTAB, UXTAB16, and UXTAH instructions.

All other values are reserved.

In ARMv8-A the only permitted value is 0010.

Except_AR, bits [11:8]

Indicates the implemented A and R profile exception-handling instructions. Defined values are:

0000 None implemented.

0001 Adds the SRS and RFE instructions, and the A and R profile forms of the CPS instruction.

All other values are reserved.

In ARMv8-A the only permitted value is 0001.

Except, bits [7:4]

Indicates the implemented exception-handling instructions in the ARM instruction set. Defined values are:

0000 Not implemented. This indicates that the User bank and Exception return forms of the LDM and STM instructions are not implemented.

0001 Adds the LDM (exception return), LDM (user registers), and STM (user registers) instruction versions.

All other values are reserved.

In ARMv8-A the only permitted value is 0001.

Endian, bits [3:0]

Indicates the implemented Endian instructions. Defined values are:

0000 None implemented.

0001 Adds the SETEND instruction, and the E bit in the PSRs.

All other values are reserved.

In ARMv8-A the permitted values are 0000 and 0001.

Accessing the ID_ISAR1

This register can be read using MRC with the following syntax:

MRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c0, c2, 1	000	001	0000	1111	0010

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	RO	n/a	RO
x	0	1	-	RO	RO	RO
x	1	1	-	n/a	RO	RO

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If HCR_EL2.TID3==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If HCR_EL2.TID3==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HCR.TID3==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
 - If HSTR.T0==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.

G6.2.82 ID_ISAR2, Instruction Set Attribute Register 2

The ID_ISAR2 characteristics are:

Purpose

Provides information about the instruction sets implemented by the PE in AArch32 state.

Must be interpreted with ID_ISAR0, ID_ISAR1, ID_ISAR3, ID_ISAR4, and ID_ISAR5.

For general information about the interpretation of the ID registers see *Principles of the ID scheme for fields in ID registers* on page G4-4701.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register ID_ISAR2 is architecturally mapped to AArch64 System register ID_ISAR2_EL1.

Attributes

ID_ISAR2 is a 32-bit register.

Field descriptions

The ID_ISAR2 bit assignments are:

Reversal, bits [31:28]

Indicates the implemented Reversal instructions. Defined values are:

- 0000 None implemented.
- 0001 Adds the REV, REV16, and REVSH instructions.
- 0010 As for 0001, and adds the RBIT instruction.

All other values are reserved.

In ARMv8-A the only permitted value is 0010.

PSR_AR, bits [27:24]

Indicates the implemented A and R profile instructions to manipulate the PSR. Defined values are:

- 0000 None implemented.
- 0001 Adds the MRS and MSR instructions, and the exception return forms of data-processing instructions.

All other values are reserved.

In ARMv8-A the only permitted value is 0001.

The exception return forms of the data-processing instructions are:

- In the A32 instruction set, data-processing instructions with the PC as the destination and the S bit set. These instructions might be affected by the WithShifts attribute.
- In the T32 instruction set, the SUBS PC,LR,#N instruction.

MultU, bits [23:20]

Indicates the implemented advanced unsigned Multiply instructions. Defined values are:

- 0000 None implemented.
- 0001 Adds the UMULL and UMLAL instructions.
- 0010 As for 0001, and adds the UMAAL instruction.

All other values are reserved.

In ARMv8-A the only permitted value is 0010.

MultS, bits [19:16]

Indicates the implemented advanced signed Multiply instructions. Defined values are:

- 0000 None implemented.
- 0001 Adds the SMULL and SMLAL instructions.
- 0010 As for 0001, and adds the SMLABB, SMLABT, SMLALBB, SMLALBT, SMLALTB, SMLALTT, SMLATB, SMLATT, SMLAWB, SMLAWT, SMULBB, SMULBT, SMULTB, SMULTT, SMULWB, and SMULWT instructions. Also adds the Q bit in the PSRs.
- 0011 As for 0010, and adds the SMLAD, SMLADX, SMLALD, SMLALDX, SMLSD, SMLSDX, SMLSLD, SMLSLDX, SMMLA, SMMLAR, SMMLS, SMMLSR, SMMUL, SMMULR, SMUAD, SMUADX, SMUSD, and SMUSDX instructions.

All other values are reserved.

In ARMv8-A the only permitted value is 0011.

Mult, bits [15:12]

Indicates the implemented additional Multiply instructions. Defined values are:

- 0000 No additional instructions implemented. This means only MUL is implemented.
- 0001 Adds the MLA instruction.
- 0010 As for 0001, and adds the MLS instruction.

All other values are reserved.

In ARMv8-A the only permitted value is 0010.

MultiAccessInt, bits [11:8]

Indicates the support for interruptible multi-access instructions. Defined values are:

- 0000 No support. This means the LDM and STM instructions are not interruptible.
- 0001 LDM and STM instructions are restartable.
- 0010 LDM and STM instructions are continuable.

All other values are reserved.

In ARMv8-A the only permitted value is 0000.

MemHint, bits [7:4]

Indicates the implemented Memory Hint instructions. Defined values are:

- 0000 None implemented.
- 0001 Adds the PLD instruction.
- 0010 Adds the PLD instruction. (0001 and 0010 have identical effects.)
- 0011 As for 0001 (or 0010), and adds the PLI instruction.
- 0100 As for 0011, and adds the PLDW instruction.

All other values are reserved.

In ARMv8-A the only permitted value is 0100.

LoadStore, bits [3:0]

Indicates the implemented additional load/store instructions. Defined values are:

- 0000 No additional load/store instructions implemented.
- 0001 Adds the LDRD and STRD instructions.
- 0010 As for 0001, and adds the Load Acquire (LDAB, LDAH, LDA, LDAEXB, LDAEXH, LDAEX, LDAEXD) and Store Release (STLB, STLH, STL, STLEXB, STLEXH, STLEX, STLEXD) instructions.

All other values are reserved.

In ARMv8-A the only permitted value is 0010.

Accessing the ID_ISAR2

This register can be read using MRC with the following syntax:

MRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c0, c2, 2	000	010	0000	1111	0010

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	RO	n/a	RO
x	0	1	-	RO	RO	RO
x	1	1	-	n/a	RO	RO

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If HCR_EL2.TID3==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If HCR_EL2.TID3==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HCR.TID3==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
 - If HSTR.T0==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.

G6.2.83 ID_ISAR3, Instruction Set Attribute Register 3

The ID_ISAR3 characteristics are:

Purpose

Provides information about the instruction sets implemented by the PE in AArch32 state.

Must be interpreted with ID_ISAR0, ID_ISAR1, ID_ISAR2, ID_ISAR4, and ID_ISAR5.

For general information about the interpretation of the ID registers see *Principles of the ID scheme for fields in ID registers* on page G4-4701.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register ID_ISAR3 is architecturally mapped to AArch64 System register ID_ISAR3_EL1.

Attributes

ID_ISAR3 is a 32-bit register.

Field descriptions

The ID_ISAR3 bit assignments are:

31	28 27	24 23	20 19	16 15	12 11	8 7	4 3	0
T32EE	TrueNOP	T32Copy	TabBranch	SynchPrim	SVC	SIMD	Saturate	

T32EE, bits [31:28]

Indicates the implemented T32EE instructions. Defined values are:

0000 None implemented.

0001 Adds the ENTERX and LEAVEX instructions, and modifies the load behavior to include null checking.

All other values are reserved.

In ARMv8-A the only permitted value is 0000.

TrueNOP, bits [27:24]

Indicates the implemented true NOP instructions. Defined values are:

0000 None implemented. This means there are no NOP instructions that do not have any register dependencies.

0001 Adds true NOP instructions in both the T32 and A32 instruction sets. This also permits additional NOP-compatible hints.

All other values are reserved.

In ARMv8-A the only permitted value is 0001.

T32Copy, bits [23:20]

Indicates the support for T32 non flag-setting MOV instructions. Defined values are:

0000 Not supported. This means that in the T32 instruction set, encoding T1 of the MOV (register) instruction does not support a copy from a low register to a low register.

0001 Adds support for T32 instruction set encoding T1 of the MOV (register) instruction, copying from a low register to a low register.

All other values are reserved.

In ARMv8-A the only permitted value is 0001.

TabBranch, bits [19:16]

Indicates the implemented Table Branch instructions in the T32 instruction set. Defined values are:

- 0000 None implemented.
- 0001 Adds the TBB and TBH instructions.

All other values are reserved.

In ARMv8-A the only permitted value is 0001.

SynchPrim, bits [15:12]

Used in conjunction with ID_ISAR4.SynchPrim_frac to indicate the implemented Synchronization Primitive instructions. Defined values are:

- 0000 If SynchPrim_frac == 0000, no Synchronization Primitives implemented.
- 0001 If SynchPrim_frac == 0000, adds the LDREX and STREX instructions.
If SynchPrim_frac == 0011, also adds the CLREX, LDREXB, STREXB, and STREXH instructions.
- 0010 If SynchPrim_frac == 0000, as for [0001, 0011] and also adds the LDREXD and STREXD instructions.

All other combinations of SynchPrim and SynchPrim_frac are reserved.

In ARMv8-A the only permitted value is 0010.

SVC, bits [11:8]

Indicates the implemented SVC instructions. Defined values are:

- 0000 Not implemented.
- 0001 Adds the SVC instruction.

All other values are reserved.

In ARMv8-A the only permitted value is 0001.

SIMD, bits [7:4]

Indicates the implemented SIMD instructions. Defined values are:

- 0000 None implemented.
- 0001 Adds the SSAT and USAT instructions, and the Q bit in the PSRs.
- 0011 As for 0001, and adds the PKHBT, PKHTB, QADD16, QADD8, QASX, QSUB16, QSUB8, QSAX, SADD16, SADD8, SASX, SEL, SHADD16, SHADD8, SHASX, SHSUB16, SHSUB8, SHSAX, SSAT16, SSUB16, SSUB8, SSAX, SXTAB16, SXTB16, UADD16, UADD8, UASX, UHADD16, UHADD8, UHASX, UHSUB16, UHSUB8, UHSAX, UQADD16, UQADD8, UQASX, UQSUB16, UQSUB8, UQSAX, USAD8, USADA8, USAT16, USUB16, USUB8, USAX, UXTAB16, and UXTB16 instructions. Also adds support for the GE[3:0] bits in the PSRs.

All other values are reserved.

In ARMv8-A the only permitted value is 0011.

The SIMD field relates only to implemented instructions that perform SIMD operations on the general-purpose registers. In an implementation that supports floating-point and Advanced SIMD instructions, [MVFR0](#), [MVFR1](#), and [MVFR2](#) give information about the implemented Advanced SIMD instructions.

Saturate, bits [3:0]

Indicates the implemented Saturate instructions. Defined values are:

- 0000 None implemented. This means no non-Advanced SIMD saturate instructions are implemented.
- 0001 Adds the QADD, QDADD, QDSUB, and QSUB instructions, and the Q bit in the PSRs.

All other values are reserved.

In ARMv8-A the only permitted value is 0001.

Accessing the ID_ISAR3

This register can be read using MRC with the following syntax:

MRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c0, c2, 3	000	011	0000	1111	0010

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	RO	n/a	RO
x	0	1	-	RO	RO	RO
x	1	1	-	n/a	RO	RO

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If HCR_EL2.TID3==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If HCR_EL2.TID3==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HCR.TID3==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
 - If HSTR.T0==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.

G6.2.84 ID_ISAR4, Instruction Set Attribute Register 4

The ID_ISAR4 characteristics are:

Purpose

Provides information about the instruction sets implemented by the PE in AArch32 state.

Must be interpreted with ID_ISAR0, ID_ISAR1, ID_ISAR2, ID_ISAR3, and ID_ISAR5.

For general information about the interpretation of the ID registers see *Principles of the ID scheme for fields in ID registers* on page G4-4701.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register ID_ISAR4 is architecturally mapped to AArch64 System register ID_ISAR4_EL1.

Attributes

ID_ISAR4 is a 32-bit register.

Field descriptions

The ID_ISAR4 bit assignments are:

SWP_frac, bits [31:28]

Indicates support for the memory system locking the bus for SWP or SWPB instructions. Defined values are:

0000 SWP or SWPB instructions not implemented.

0001 SWP or SWPB implemented but only in a uniprocessor context. SWP and SWPB do not guarantee whether memory accesses from other masters can come between the load memory access and the store memory access of the SWP or SWPB.

All other values are reserved. This field is valid only if the ID_ISAR0.Swap_insts field is 0000.

In ARMv8-A the only permitted value is 0000.

PSR_M, bits [27:24]

Indicates the implemented M profile instructions to modify the PSRs. Defined values are:

0000 None implemented.

0001 Adds the M profile forms of the CPS, MRS, and MSR instructions.

All other values are reserved.

In ARMv8-A the only permitted value is 0000.

SynchPrim_frac, bits [23:20]

Used in conjunction with ID_ISAR3.SynchPrim to indicate the implemented Synchronization Primitive instructions. Possible values are:

0000 If SynchPrim == 0000, no Synchronization Primitives implemented. If SynchPrim == 0001, adds the LDREX and STREX instructions. If SynchPrim == 0010, also adds the CLREX, LDREXB, LDREXH, STREXB, STREXH, LDREXD, and STREXD instructions.

0011 If SynchPrim == 0001, adds the LDREX, STREX, CLREX, LDREXB, LDREXH, STREXB, and STREXH instructions.

All other combinations of SynchPrim and SynchPrim_frac are reserved.

In ARMv8-A the only permitted value is 0000.

Barrier, bits [19:16]

Indicates the implemented Barrier instructions in the A32 and T32 instruction sets. Defined values are:

0000 None implemented. Barrier operations are provided only as System instructions in the (coproc==1111) encoding space.

0001 Adds the DMB, DSB, and ISB barrier instructions.

All other values are reserved.

In ARMv8-A the only permitted value is 0001.

SMC, bits [15:12]

Indicates the implemented SMC instructions. Defined values are:

0000 None implemented.

0001 Adds the SMC instruction.

All other values are reserved.

In ARMv8-A the only permitted value is 0001.

Writeback, bits [11:8]

Indicates the support for Writeback addressing modes. Defined values are:

0000 Basic support. Only the LDM, STM, PUSH, POP, SRS, and RFE instructions support writeback addressing modes. These instructions support all of their writeback addressing modes.

0001 Adds support for all of the writeback addressing modes.

All other values are reserved.

In ARMv8-A the only permitted value is 0001.

WithShifts, bits [7:4]

Indicates the support for instructions with shifts. Defined values are:

0000 Nonzero shifts supported only in MOV and shift instructions.

0001 Adds support for shifts of loads and stores over the range LSL 0-3.

0011 As for 0001, and adds support for other constant shift options, both on load/store and other instructions.

0100 As for 0011, and adds support for register-controlled shift options.

All other values are reserved.

In ARMv8-A the only permitted value is 0100.

Unpriv, bits [3:0]

Indicates the implemented unprivileged instructions. Defined values are:

0000 None implemented. No T variant instructions are implemented.

0001 Adds the LDRBT, LDRT, STRBT, and STRT instructions.

0010 As for 0001, and adds the LDRHT, LDRSBT, LDRSHT, and STRHT instructions.

All other values are reserved.

In ARMv8-A the only permitted value is 0010.

Accessing the ID_ISAR4

This register can be read using MRC with the following syntax:

MRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c0, c2, 4	000	100	0000	1111	0010

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	RO	n/a	RO
x	0	1	-	RO	RO	RO
x	1	1	-	n/a	RO	RO

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If HCR_EL2.TID3==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If HCR_EL2.TID3==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HCR.TID3==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
 - If HSTR.T0==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.

G6.2.85 ID_ISAR5, Instruction Set Attribute Register 5

The ID_ISAR5 characteristics are:

Purpose

Provides information about the instruction sets implemented by the PE in AArch32 state.

Must be interpreted with ID_ISAR0, ID_ISAR1, ID_ISAR2, ID_ISAR3, and ID_ISAR4.

For general information about the interpretation of the ID registers see *Principles of the ID scheme for fields in ID registers* on page G4-4701.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register ID_ISAR5 is architecturally mapped to AArch64 System register ID_ISAR5_EL1.

Attributes

ID_ISAR5 is a 32-bit register.

Field descriptions

The ID_ISAR5 bit assignments are:

31	28 27	24 23	20 19	16 15	12 11	8 7	4 3	0
RES0	RDM	RES0	CRC32	SHA2	SHA1	AES	SEVL	

Bits [31:28]

Reserved, RES0.

RDM, bits [27:24]

In ARMv8.2 and ARMv8.1

Indicates whether the VQRDMLAH and VQRDMLSH instructions are implemented in AArch32 state. Defined values are:

0000 No VQRDMLAH and VQRDMLSH instructions implemented.

0001 VQRDMLAH and VQRDMLSH instructions implemented.

All other values are reserved.

In ARMv8.0 the only permitted value is 0000.

From ARMv8.1 the only permitted value is 0001. This feature is identified by the name [ARMv8.1-SIMD](#).

In ARMv8.0.

Reserved, RES0.

Bits [23:20]

Reserved, RES0.

CRC32, bits [19:16]

Indicates whether the CRC32 instructions are implemented in AArch32 state.

0000 No CRC32 instructions implemented.

0001 CRC32B, CRC32H, CRC32W, CRC32CB, CRC32CH, and CRC32CW instructions implemented.

All other values are reserved.

In ARMv8.0 the permitted values are 0000 and 0001.

From ARMv8.1 the only permitted value is 0001.

SHA2, bits [15:12]

Indicates whether the SHA2 instructions are implemented in AArch32 state.

0000 No SHA2 instructions implemented.

0001 SHA256H, SHA256H2, SHA256SU0, and SHA256SU1 implemented.

All other values are reserved.

In ARMv8-A the permitted values are 0000 and 0001.

SHA1, bits [11:8]

Indicates whether the SHA1 instructions are implemented in AArch32 state.

0000 No SHA1 instructions implemented.

0001 SHA1C, SHA1P, SHA1M, SHA1H, SHA1SU0, and SHA1SU1 implemented.

All other values are reserved.

In ARMv8-A the permitted values are 0000 and 0001.

AES, bits [7:4]

Indicates whether the AES instructions are implemented in AArch32 state.

0000 No AES instructions implemented.

0001 AESE, AESD, AESMC, and AESIMC implemented.

0010 As for 0001, plus PMULL/PMULL2 instructions operating on 64-bit data quantities.

All other values are reserved.

In ARMv8-A the permitted values are 0000 and 0010.

SEVL, bits [3:0]

Indicates whether the SEVL instruction is implemented in AArch32 state.

0000 SEVL is implemented as a NOP.

0001 SEVL is implemented as Send Event Local.

All other values are reserved.

In ARMv8-A the only permitted value is 0001.

Accessing the ID_ISAR5

This register can be read using MRC with the following syntax:

MRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c0, c2, 5	000	101	0000	1111	0010

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	RO	n/a	RO
x	0	1	-	RO	RO	RO
x	1	1	-	n/a	RO	RO

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If HCR_EL2.TID3==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If HCR_EL2.TID3==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HCR.TID3==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
 - If HSTR.T0==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.

G6.2.86 ID_MMFR0, Memory Model Feature Register 0

The ID_MMFR0 characteristics are:

Purpose

Provides information about the implemented memory model and memory management support in AArch32 state.

Must be interpreted with ID_MMFR1, ID_MMFR2, ID_MMFR3, and ID_MMFR4.

For general information about the interpretation of the ID registers see *Principles of the ID scheme for fields in ID registers* on page G4-4701.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register ID_MMFR0 is architecturally mapped to AArch64 System register ID_MMFR0_EL1.

Attributes

ID_MMFR0 is a 32-bit register.

Field descriptions

The ID_MMFR0 bit assignments are:

31	28 27	24 23	20 19	16 15	12 11	8 7	4 3	0
InnerShr	FCSE	AuxReg	TCM	ShareLvl	OuterShr	PMSA	VMSA	

InnerShr, bits [31:28]

Innermost Shareability. Indicates the innermost shareability domain implemented. Defined values are:

- 0000 Implemented as Non-cacheable.
- 0001 Implemented with hardware coherency support.
- 1111 Shareability ignored.

All other values are reserved.

In ARMv8 the permitted values are 0000, 0001, and 1111.

This field is valid only if the implementation supports two levels of shareability, as indicated by ID_MMFR0.ShareLvl having the value 0001.

When ID_MMFR0.ShareLvl is zero, this field is UNK.

FCSE, bits [27:24]

Indicates whether the implementation includes the FCSE. Defined values are:

- 0000 Not supported.
- 0001 Support for FCSE.

All other values are reserved.

In ARMv8 the only permitted value is 0000.

AuxReg, bits [23:20]

Auxiliary Registers. Indicates support for Auxiliary registers. Defined values are:

- 0000 None supported.
- 0001 Support for Auxiliary Control Register only.

0010 Support for Auxiliary Fault Status Registers (**AIFSR** and **ADFSR**) and Auxiliary Control Register.

All other values are reserved.

In ARMv8 the only permitted value is 0010.

———— **Note** ————

Accesses to unimplemented Auxiliary registers are UNDEFINED.

TCM, bits [19:16]

Indicates support for TCMs and associated DMAs. Defined values are:

0000 Not supported.

0001 Support is IMPLEMENTATION DEFINED. ARMv7 requires this setting.

0010 Support for TCM only, ARMv6 implementation.

0011 Support for TCM and DMA, ARMv6 implementation.

All other values are reserved.

In ARMv8-A the only permitted value is 0000.

ShareLvl, bits [15:12]

Shareability Levels. Indicates the number of shareability levels implemented. Defined values are:

0000 One level of shareability implemented.

0001 Two levels of shareability implemented.

All other values are reserved.

In ARMv8 the only permitted value is 0001.

OuterShr, bits [11:8]

Outermost Shareability. Indicates the outermost shareability domain implemented. Defined values are:

0000 Implemented as Non-cacheable.

0001 Implemented with hardware coherency support.

1111 Shareability ignored.

All other values are reserved.

In ARMv8 the permitted values are 0000, 0001, and 1111.

PMSA, bits [7:4]

Indicates support for a PMSA. Defined values are:

0000 Not supported.

0001 Support for IMPLEMENTATION DEFINED PMSA.

0010 Support for PMSAv6, with a Cache Type Register implemented.

0011 Support for PMSAv7, with support for memory subsections. ARMv7-R profile.

All other values are reserved.

In ARMv8-A the only permitted value is 0000.

VMSA, bits [3:0]

Indicates support for a VMSA. Defined values are:

0000 Not supported.

0001 Support for IMPLEMENTATION DEFINED VMSA.

0010 Support for VMSAv6, with Cache and TLB Type Registers implemented.

- 0011 Support for VMSAv7, with support for remapping and the Access flag. ARMv7-A profile.
 - 0100 As for 0011, and adds support for the PXN bit in the Short-descriptor translation table format descriptors.
 - 0101 As for 0100, and adds support for the Long-descriptor translation table format.
- All other values are reserved.
- In ARMv8-A the only permitted value is 0101.

Accessing the ID_MMFR0

This register can be read using MRC with the following syntax:

MRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c0, c1, 4	000	100	0000	1111	0001

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	RO	n/a	RO
x	0	1	-	RO	RO	RO
x	1	1	-	n/a	RO	RO

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If HCR_EL2.TID3==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If HCR_EL2.TID3==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HCR.TID3==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
 - If HSTR.T0==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.

G6.2.87 ID_MMFR1, Memory Model Feature Register 1

The ID_MMFR1 characteristics are:

Purpose

Provides information about the implemented memory model and memory management support in AArch32 state.

Must be interpreted with [ID_MMFR0](#), [ID_MMFR2](#), [ID_MMFR3](#), and [ID_MMFR4](#).

For general information about the interpretation of the ID registers see *Principles of the ID scheme for fields in ID registers* on page G4-4701.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register ID_MMFR1 is architecturally mapped to AArch64 System register [ID_MMFR1_EL1](#).

Attributes

ID_MMFR1 is a 32-bit register.

Field descriptions

The ID_MMFR1 bit assignments are:

31	28 27	24 23	20 19	16 15	12 11	8 7	4 3	0
BPred	L1TstCln	L1Uni	L1Hvd	L1UniSW	L1HvdSW	L1UniVA	L1HvdVA	

BPred, bits [31:28]

Branch Predictor. Indicates branch predictor management requirements. Defined values are:

0000 No branch predictor, or no MMU present. Implies a fixed MPU configuration.

0001 Branch predictor requires flushing on:

- Enabling or disabling a stage of address translation.
- Writing new data to instruction locations.
- Writing new mappings to the translation tables.
- Changes to the [TTBR0](#), [TTBR1](#), or [TTBCR](#) registers.
- Changes to the ContextID or ASID, or to the FCSE ProcessID if this is supported.

0010 Branch predictor requires flushing on:

- Enabling or disabling a stage of address translation.
- Writing new data to instruction locations.
- Writing new mappings to the translation tables.
- Any change to the [TTBR0](#), [TTBR1](#), or [TTBCR](#) registers without a change to the corresponding ContextID or ASID, or FCSE ProcessID if this is supported.

0011 Branch predictor requires flushing only on writing new data to instruction locations.

0100 For execution correctness, branch predictor requires no flushing at any time.

All other values are reserved.

In ARMv8-A the permitted values are 0010, 0011, or 0100. For values other than 0000 and 0100 the ARM Architecture Reference Manual, or the product documentation, might give more information about the required maintenance.

L1TstCln, bits [27:24]

Level 1 cache Test and Clean. Indicates the supported Level 1 data cache test and clean operations, for Harvard or unified cache implementations. Defined values are:

- 0000 None supported.
- 0001 Supported Level 1 data cache test and clean operations are:
- Test and clean data cache.
- 0010 As for 0001, and adds:
- Test, clean, and invalidate data cache.

All other values are reserved.

In ARMv8-A the only permitted value is 0000.

L1Uni, bits [23:20]

Level 1 Unified cache. Indicates the supported entire Level 1 cache maintenance operations for a unified cache implementation. Defined values are:

- 0000 None supported.
- 0001 Supported entire Level 1 cache operations are:
- Invalidate cache, including branch predictor if appropriate.
 - Invalidate branch predictor, if appropriate.
- 0010 As for 0001, and adds:
- Clean cache, using a recursive model that uses the cache dirty status bit.
 - Clean and invalidate cache, using a recursive model that uses the cache dirty status bit.

All other values are reserved.

In ARMv8-A the only permitted value is 0000.

L1Hvd, bits [19:16]

Level 1 Harvard cache. Indicates the supported entire Level 1 cache maintenance operations for a Harvard cache implementation. Defined values are:

- 0000 None supported.
- 0001 Supported entire Level 1 cache operations are:
- Invalidate instruction cache, including branch predictor if appropriate.
 - Invalidate branch predictor, if appropriate.
- 0010 As for 0001, and adds:
- Invalidate data cache.
 - Invalidate data cache and instruction cache, including branch predictor if appropriate.
- 0011 As for 0010, and adds:
- Clean data cache, using a recursive model that uses the cache dirty status bit.
 - Clean and invalidate data cache, using a recursive model that uses the cache dirty status bit.

All other values are reserved.

In ARMv8-A the only permitted value is 0000.

L1UniSW, bits [15:12]

Level 1 Unified cache by Set/Way. Indicates the supported Level 1 cache line maintenance operations by set/way, for a unified cache implementation. Defined values are:

- 0000 None supported.

0001 Supported Level 1 unified cache line maintenance operations by set/way are:

- Clean cache line by set/way.

0010 As for 0001, and adds:

- Clean and invalidate cache line by set/way.

0011 As for 0010, and adds:

- Invalidate cache line by set/way.

All other values are reserved.

In ARMv8-A the only permitted value is 0000.

L1HvdSW, bits [11:8]

Level 1 Harvard cache by Set/Way. Indicates the supported Level 1 cache line maintenance operations by set/way, for a Harvard cache implementation. Defined values are:

0000 None supported.

0001 Supported Level 1 Harvard cache line maintenance operations by set/way are:

- Clean data cache line by set/way.
- Clean and invalidate data cache line by set/way.

0010 As for 0001, and adds:

- Invalidate data cache line by set/way.

0011 As for 0010, and adds:

- Invalidate instruction cache line by set/way.

All other values are reserved.

In ARMv8-A the only permitted value is 0000.

L1UniVA, bits [7:4]

Level 1 Unified cache by Virtual Address. Indicates the supported Level 1 cache line maintenance operations by VA, for a unified cache implementation. Defined values are:

0000 None supported.

0001 Supported Level 1 unified cache line maintenance operations by VA are:

- Clean cache line by VA.
- Invalidate cache line by VA.
- Clean and invalidate cache line by VA.

0010 As for 0001, and adds:

- Invalidate branch predictor by VA, if branch predictor is implemented.

All other values are reserved.

In ARMv8-A the only permitted value is 0000.

L1HvdVA, bits [3:0]

Level 1 Harvard cache by Virtual Address. Indicates the supported Level 1 cache line maintenance operations by VA, for a Harvard cache implementation. Defined values are:

0000 None supported.

0001 Supported Level 1 Harvard cache line maintenance operations by VA are:

- Clean data cache line by VA.
- Invalidate data cache line by VA.
- Clean and invalidate data cache line by VA.
- Clean instruction cache line by VA.

0010 As for 0001, and adds:

- Invalidate branch predictor by VA, if branch predictor is implemented.

All other values are reserved.
 In ARMv8-A the only permitted value is 0000.

Accessing the ID_MMFR1

This register can be read using MRC with the following syntax:

MRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c0, c1, 5	000	101	0000	1111	0001

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	RO	n/a	RO
x	0	1	-	RO	RO	RO
x	1	1	-	n/a	RO	RO

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If HCR_EL2.TID3==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If HCR_EL2.TID3==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HCR.TID3==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
 - If HSTR.T0==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.

G6.2.88 ID_MMFR2, Memory Model Feature Register 2

The ID_MMFR2 characteristics are:

Purpose

Provides information about the implemented memory model and memory management support in AArch32 state.

Must be interpreted with ID_MMFR0, ID_MMFR1, ID_MMFR3, and ID_MMFR4.

For general information about the interpretation of the ID registers see *Principles of the ID scheme for fields in ID registers* on page G4-4701.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register ID_MMFR2 is architecturally mapped to AArch64 System register ID_MMFR2_EL1.

Attributes

ID_MMFR2 is a 32-bit register.

Field descriptions

The ID_MMFR2 bit assignments are:

31	28 27	24 23	20 19	16 15	12 11	8 7	4 3	0
HWAccFlg	WFIStall	MemBarr	UniTLB	HvdTLB	L1HvdRng	L1HvdBG	L1HvdFG	

HWAccFlg, bits [31:28]

Hardware Access Flag. In earlier versions of the ARM Architecture, this field indicates support for a Hardware Access flag, as part of the VMSAv7 implementation. Defined values are:

0000 Not supported.

0001 Support for VMSAv7 Access flag, updated in hardware.

All other values are reserved.

In ARMv8 the only permitted value is 0000.

WFIStall, bits [27:24]

Wait For Interrupt Stall. Indicates the support for Wait For Interrupt (WFI) stalling. Defined values are:

0000 Not supported.

0001 Support for WFI stalling.

All other values are reserved.

In ARMv8 the permitted values are 0000 and 0001.

MemBarr, bits [23:20]

Memory Barrier. Indicates the supported memory barrier System instructions in the (coproc==1111) encoding space:

0000 None supported.

0001 Supported memory barrier System instructions are:

- Data Synchronization Barrier (DSB).

0010 As for 0001, and adds:

- Instruction Synchronization Barrier (ISB).

- Data Memory Barrier (DMB).

All other values are reserved.

In ARMv8 the only permitted value is 0010.

ARM deprecates the use of these operations. ID_ISAR4.Barrier_instrs indicates the level of support for the preferred barrier instructions.

UniTLB, bits [19:16]

Unified TLB. Indicates the supported TLB maintenance operations, for a unified TLB implementation. Defined values are:

- | | |
|------|---|
| 0000 | Not supported. |
| 0001 | Supported unified TLB maintenance operations are: <ul style="list-style-type: none">• Invalidate all entries in the TLB.• Invalidate TLB entry by VA. |
| 0010 | As for 0001, and adds: <ul style="list-style-type: none">• Invalidate TLB entries by ASID match. |
| 0011 | As for 0010, and adds: <ul style="list-style-type: none">• Invalidate instruction TLB and data TLB entries by VA All ASID. This is a shared unified TLB operation. |
| 0100 | As for 0011, and adds: <ul style="list-style-type: none">• Invalidate Hyp mode unified TLB entry by VA.• Invalidate entire Non-secure PL1&0 unified TLB.• Invalidate entire Hyp mode unified TLB. |
| 0101 | As for 0100, and adds the following operations: TLBIMVALIS , TLBIMVAALIS , TLBIMVALHIS , TLBIMVAL , TLBIMVAAL , TLBIMVALH . |
| 0110 | As for 0101, and adds the following operations: TLBIIPAS2IS , TLBIIPAS2LIS , TLBIIPAS2 , TLBIIPAS2L . |

All other values are reserved.

In ARMv8-A the only permitted value is 0110.

HvdTLB, bits [15:12]

If the Unified TLB field (UniTLB, bits [19:16]) is not 0000, then the meaning of this field is IMPLEMENTATION DEFINED. ARM deprecates the use of this field by software.

L1HvdRng, bits [11:8]

Level 1 Harvard cache Range. Indicates the supported Level 1 cache maintenance range operations, for a Harvard cache implementation. Defined values are:

- | | |
|------|---|
| 0000 | Not supported. |
| 0001 | Supported Level 1 Harvard cache maintenance range operations are: <ul style="list-style-type: none">• Invalidate data cache range by VA.• Invalidate instruction cache range by VA.• Clean data cache range by VA.• Clean and invalidate data cache range by VA. |

All other values are reserved.

In ARMv8 the only permitted value is 0000.

L1HvdBG, bits [7:4]

Level 1 Harvard cache Background fetch. Indicates the supported Level 1 cache background fetch operations, for a Harvard cache implementation. When supported, background fetch operations are non-blocking operations. Defined values are:

0000 Not supported.

0001 Supported Level 1 Harvard cache background fetch operations are:

- Fetch instruction cache range by VA.
- Fetch data cache range by VA.

All other values are reserved.

In ARMv8 the only permitted value is 0000.

L1HvdFG, bits [3:0]

Level 1 Harvard cache Foreground fetch. Indicates the supported Level 1 cache foreground fetch operations, for a Harvard cache implementation. When supported, foreground fetch operations are blocking operations. Defined values are:

0000 Not supported.

0001 Supported Level 1 Harvard cache foreground fetch operations are:

- Fetch instruction cache range by VA.
- Fetch data cache range by VA.

All other values are reserved.

In ARMv8 the only permitted value is 0000.

Accessing the ID_MMFR2

This register can be read using MRC with the following syntax:

MRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c0, c1, 6	000	110	0000	1111	0001

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	RO	n/a	RO
x	0	1	-	RO	RO	RO
x	1	1	-	n/a	RO	RO

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \&\& (HCR_EL2.E2H == 0)$:
 - If $HCR_EL2.TID3 == 1$, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If $HSTR_EL2.T0 == 1$, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \&\& (HCR_EL2.E2H == 1) \&\& (HCR_EL2.TGE == 0)$:
 - If $HCR_EL2.TID3 == 1$, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If $HSTR_EL2.T0 == 1$, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $HCR.TID3 == 1$, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
 - If $HSTR.T0 == 1$, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.

G6.2.89 ID_MMFR3, Memory Model Feature Register 3

The ID_MMFR3 characteristics are:

Purpose

Provides information about the implemented memory model and memory management support in AArch32 state.

Must be interpreted with ID_MMFR0, ID_MMFR1, ID_MMFR2, and ID_MMFR4.

For general information about the interpretation of the ID registers see *Principles of the ID scheme for fields in ID registers* on page G4-4701.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register ID_MMFR3 is architecturally mapped to AArch64 System register ID_MMFR3_EL1.

Attributes

ID_MMFR3 is a 32-bit register.

Field descriptions

The ID_MMFR3 bit assignments are:

31	28 27	24 23	20 19	16 15	12 11	8 7	4 3	0
Supersec	CMemSz	CohWalk	PAN	MaintBcst	BPMaint	CMaintSW	CMaintVA	

Supersec, bits [31:28]

Supersections. On a VMSA implementation, indicates whether Supersections are supported.

Defined values are:

0000 Supersections supported.

1111 Supersections not supported.

All other values are reserved.

In ARMv8-A the permitted values are 0000 and 1111.

CMemSz, bits [27:24]

Cached Memory Size. Indicates the physical memory size supported by the caches. Defined values are:

0000 4GB, corresponding to a 32-bit physical address range.

0001 64GB, corresponding to a 36-bit physical address range.

0010 1TB or more, corresponding to a 40-bit or larger physical address range.

All other values are reserved.

In ARMv8-A the permitted values are 0000, 0001, and 0010.

CohWalk, bits [23:20]

Coherent Walk. Indicates whether Translation table updates require a clean to the point of unification. Defined values are:

0000 Updates to the translation tables require a clean to the point of unification to ensure visibility by subsequent translation table walks.

0001 Updates to the translation tables do not require a clean to the point of unification to ensure visibility by subsequent translation table walks.

All other values are reserved.
In ARMv8-A the only permitted value is 0001.

PAN, bits [19:16]

In ARMv8.2 and ARMv8.1

Privileged Access Never. Indicates support for the PAN bit in [CPSR](#), [SPSR](#), and [DSPSR](#) in AArch32. Defined values are:

- 0000 PAN not supported.
- 0001 PAN supported.
- 0010 PAN supported and [ATS1CPRP](#) and [ATS1CPWP](#) instructions supported.

All other values are reserved.

In ARMv8.0 the only permitted value is 0000.

In ARMv8.1 the only permitted value is 0001. This feature is identified by the name [ARMv8.1-PAN](#).

From ARMv8.2, the only permitted value is 0010. This feature is identified by the name [ARMv8.2-ATS1E1](#).

In ARMv8.0.

Reserved, RES0.

MaintBcst, bits [15:12]

Maintenance Broadcast. Indicates whether Cache, TLB, and branch predictor operations are broadcast. Defined values are:

- 0000 Cache, TLB, and branch predictor operations only affect local structures.
- 0001 Cache and branch predictor operations affect structures according to shareability and defined behavior of instructions. TLB operations only affect local structures.
- 0010 Cache, TLB, and branch predictor operations affect structures according to shareability and defined behavior of instructions.

All other values are reserved.

In ARMv8-A the only permitted value is 0010.

BPMaint, bits [11:8]

Branch Predictor Maintenance. Indicates the supported branch predictor maintenance operations in an implementation with hierarchical cache maintenance operations. Defined values are:

- 0000 None supported.
- 0001 Supported branch predictor maintenance operations are:
 - Invalidate all branch predictors.
- 0010 As for 0001, and adds:
 - Invalidate branch predictors by VA.

All other values are reserved.

In ARMv8-A the only permitted value is 0010.

CMaintSW, bits [7:4]

Cache Maintenance by Set/Way. Indicates the supported cache maintenance operations by set/way, in an implementation with hierarchical caches. Defined values are:

- 0000 None supported.
- 0001 Supported hierarchical cache maintenance instructions by set/way are:
 - Invalidate data cache by set/way.
 - Clean data cache by set/way.
 - Clean and invalidate data cache by set/way.

All other values are reserved.

In ARMv8-A the only permitted value is 0001.

In a unified cache implementation, the data cache maintenance operations apply to the unified caches.

CMaintVA, bits [3:0]

Cache Maintenance by Virtual Address. Indicates the supported cache maintenance operations by VA, in an implementation with hierarchical caches. Defined values are:

- 0000 None supported.
- 0001 Supported hierarchical cache maintenance operations by VA are:
 - Invalidate data cache by VA.
 - Clean data cache by VA.
 - Clean and invalidate data cache by VA.
 - Invalidate instruction cache by VA.
 - Invalidate all instruction cache entries.

All other values are reserved.

In ARMv8-A the only permitted value is 0001.

In a unified cache implementation, data cache maintenance operations apply to the unified caches, and the instruction cache maintenance instructions are not implemented.

Accessing the ID_MMFR3

This register can be read using MRC with the following syntax:

MRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c0, c1, 7	000	111	0000	1111	0001

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	RO	n/a	RO
x	0	1	-	RO	RO	RO
x	1	1	-	n/a	RO	RO

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If HCR_EL2.TID3==1, Non-secure read accesses to this register from EL1 are trapped to EL2.

- If `HSTR_EL2.T0==1`, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and `(SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0)`:
 - If `HCR_EL2.TID3==1`, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If `HSTR_EL2.T0==1`, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and `SCR_EL3.NS == 1`:
 - If `HCR.TID3==1`, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
 - If `HSTR.T0==1`, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.

G6.2.90 ID_MMFR4, Memory Model Feature Register 4

The ID_MMFR4 characteristics are:

Purpose

Provides information about the implemented memory model and memory management support in AArch32 state.

Must be interpreted with [ID_MMFR0](#), [ID_MMFR1](#), [ID_MMFR2](#), and [ID_MMFR3](#).

For general information about the interpretation of the ID registers see *Principles of the ID scheme for fields in ID registers* on page G4-4701.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register ID_MMFR4 is architecturally mapped to AArch64 System register [ID_MMFR4_EL1](#).

In an implementation that does not include [ACTLR2](#) and [HACTLR2](#) this register is RAZ.

Attributes

ID_MMFR4 is a 32-bit register.

Field descriptions

The ID_MMFR4 bit assignments are:

31	24 23	20 19	16 15	12 11	8 7	4 3	0
RAZ	LSM	HPDS	CnP	XNX	AC2	SpecSEI	

Bits [31:24]

Reserved, RAZ.

LSM, bits [23:20]

In ARMv8.2

Indicates support for LSMAOE and nTLSMD bits in [HSCTLR](#) and [SCTLR](#). Defined values are:

0000 LSMAOE and nTLSMD bits not supported.

0001 LSMAOE and nTLSMD bits supported.

All other values are reserved.

In ARMv8.0 and ARMv8.1 the only permitted value is 0000.

From ARMv8.2, the permitted values are 0000 and 0001. This feature is identified by the name [ARMv8.2-LSMAOC](#).

In ARMv8.1 and ARMv8.0.

Reserved, RAZ.

HPDS, bits [19:16]

In ARMv8.2

Hierarchical permission disables bits in translation tables. Defined values are:

0000 Disabling of hierarchical controls not supported.

0001 Supports disabling of hierarchical controls using the [TTBCR2.HPD0](#), [TTBCR2.HPD1](#), and [HTCR.HPD](#) bits.

0010 Supports disabling of hierarchical controls using the [TTBCR2.HPD0](#), [TTBCR2.HPD1](#), and [HTCR.HPD](#) bits, and hardware allocation of bits[62:59] of the last level page table descriptor for IMPLEMENTATION DEFINED use.

All other values are reserved.

In ARMv8.0 and ARMv8.1 the only permitted value is 0000.

From ARMv8.2, the permitted values are 0000, 0001 and 0010. This feature is identified by the name [ARMv8.2-AA32HPD](#).

———— **Note** —————

The encoding 0000 implies that the encoding for [TTBCR2](#) is unallocated.

In ARMv8.1 and ARMv8.0.

Reserved, RAZ.

CnP, bits [15:12]

In ARMv8.2

Common not Private translations. Defined values are:

0000 Common not Private translations not supported.

0001 Common not Private translations supported.

All other values are reserved.

In ARMv8.0 and ARMv8.1 the only permitted value is 0000.

From ARMv8.2, the only permitted value is 0001. This feature is identified by the name [ARMv8.2-TTCNP](#).

In ARMv8.1 and ARMv8.0.

Reserved, RAZ.

XNX, bits [11:8]

In ARMv8.2

Support for execute never control distinction at stage 2 bit. Defined values are:

0000 Distinction between EL0 and EL1 execute permission at stage 2 not supported.

0001 Distinction between EL0 and EL1 execute permission at stage 2 supported.

All other values are reserved.

In ARMv8.0 and ARMv8.1 the only permitted value is 0000.

From ARMv8.2, the only permitted value is 0001. This feature is identified by the name [ARMv8.2-TTS2UXN](#).

In ARMv8.1 and ARMv8.0.

Reserved, RAZ.

AC2, bits [7:4]

Indicates the extension of the [ACTLR](#) and [HACTLR](#) registers using [ACTLR2](#) and [HACTLR2](#).

Defined values are:

0000 [ACTLR2](#) and [HACTLR2](#) are not implemented.

0001 [ACTLR2](#) and [HACTLR2](#) are implemented.

All other values are reserved.

In ARMv8.0 and ARMv8.1 the permitted values are 0000 and 0001.

From ARMv8.2, the only permitted value is 0001.

SpecSEI, bits [3:0]

Describes whether the PE can generate SError interrupt exceptions from speculative reads of memory, including speculative instruction fetches. The defined values of this field are:

- 0000 The PE never generates an SError interrupt due to an external abort on a speculative read.
 - 0001 The PE might generate an SError interrupt due to an external abort on a speculative read.
- All other values are reserved.

When the RAS Extension is not implemented, this field is RAZ.

Accessing the ID_MMFR4

This register can be read using MRC with the following syntax:

MRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c0, c2, 6	000	110	0000	1111	0010

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	RO	n/a	RO
x	0	1	-	RO	RO	RO
x	1	1	-	n/a	RO	RO

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If EL2 is using AArch32 and `HCR.TID3==1`, then:
 - If this register is not RAZ/WI then Non-secure EL1 read accesses to this register are trapped to Hyp mode.
 - Otherwise, it is IMPLEMENTATION DEFINED whether Non-secure EL1 read accesses to this register are trapped to Hyp mode.
- If EL2 is using AArch64 and `HCR_EL2.TID3==1`, then:
 - If this register is not RAZ/WI then Non-secure EL1 read accesses to this register are trapped to EL2.
 - Otherwise, it is IMPLEMENTATION DEFINED whether Non-secure EL1 read accesses to this register are trapped to EL2.
- If `HSTR.T0==1`, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
- If `HSTR_EL2.T0==1`, Non-secure read accesses to this register from EL1 are trapped to EL2.

G6.2.91 ID_PFR0, Processor Feature Register 0

The ID_PFR0 characteristics are:

Purpose

Gives top-level information about the instruction sets supported by the PE in AArch32 state.

Must be interpreted with ID_PFR1.

For general information about the interpretation of the ID registers see *Principles of the ID scheme for fields in ID registers* on page G4-4701.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register ID_PFR0 is architecturally mapped to AArch64 System register ID_PFR0_EL1.

Attributes

ID_PFR0 is a 32-bit register.

Field descriptions

The ID_PFR0 bit assignments are:

31	28 27	16 15	12 11	8 7	4 3	0
RAS	RES0	State3	State2	State1	State0	

RAS, bits [31:28]

RAS Extension version. The defined values of this field are:

0000 No RAS Extension.

0001 Version 1 of the RAS Extension present.

All other values are reserved.

Bits [27:16]

Reserved, RES0.

State3, bits [15:12]

T32EE instruction set support. Defined values are:

0000 Not implemented.

0001 T32EE instruction set implemented.

All other values are reserved.

In ARMv8-A the only permitted value is 0000.

State2, bits [11:8]

Jazelle extension support. Defined values are:

0000 Not implemented.

0001 Jazelle extension implemented, without clearing of JOSCR.CV on exception entry.

0010 Jazelle extension implemented, with clearing of JOSCR.CV on exception entry.

All other values are reserved.

In ARMv8-A the only permitted value is 0001.

State1, bits [7:4]

T32 instruction set support. Defined values are:

- 0000 T32 instruction set not implemented.
- 0001 T32 encodings before the introduction of Thumb-2 technology implemented:
- All instructions are 16-bit.
 - A BL or BLX is a pair of 16-bit instructions.
 - 32-bit instructions other than BL and BLX cannot be encoded.
- 0011 T32 encodings after the introduction of Thumb-2 technology implemented, for all 16-bit and 32-bit T32 basic instructions.

All other values are reserved.

In ARMv8-A the only permitted value is 0011.

State0, bits [3:0]

A32 instruction set support. Defined values are:

- 0000 A32 instruction set not implemented.
- 0001 A32 instruction set implemented.

All other values are reserved.

In ARMv8-A the only permitted value is 0001.

Accessing the ID_PFR0

This register can be read using MRC with the following syntax:

MRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c0, c1, 0	000	000	0000	1111	0001

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	RO	n/a	RO
x	0	1	-	RO	RO	RO
x	1	1	-	n/a	RO	RO

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 0)$:
 - If $HCR_EL2.TID3 == 1$, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If $HSTR_EL2.T0 == 1$, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 1) \ \&\& \ (HCR_EL2.TGE == 0)$:
 - If $HCR_EL2.TID3 == 1$, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If $HSTR_EL2.T0 == 1$, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $HCR.TID3 == 1$, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
 - If $HSTR.T0 == 1$, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.

G6.2.92 ID_PFR1, Processor Feature Register 1

The ID_PFR1 characteristics are:

Purpose

Gives information about the AArch32 programmers' model.

Must be interpreted with ID_PFR0.

For general information about the interpretation of the ID registers see *Principles of the ID scheme for fields in ID registers* on page G4-4701.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register ID_PFR1 is architecturally mapped to AArch64 System register ID_PFR1_EL1.

Attributes

ID_PFR1 is a 32-bit register.

Field descriptions

The ID_PFR1 bit assignments are:

GIC, bits [31:28]

System register GIC CPU interface. Defined values are:

- 0000 No System register interface to the GIC CPU interface is supported.
 - 0001 System register interface to versions 3.0 and 4.0 of the GIC CPU interface is supported.
- All other values are reserved.

Virt_frac, bits [27:24]

Virtualization fractional field. When the Virtualization field is 0000, determines the support for features from the ARMv7 Virtualization Extensions. Defined values are:

- 0000 No features from the ARMv7 Virtualization Extensions are implemented.
- 0001 The following features of the ARMv7 Virtualization Extensions are implemented:
 - The SCR.SIF bit, if EL3 is implemented.
 - The modifications to the SCR.AW and SCR.FW bits described in the Virtualization Extensions, if EL3 is implemented.
 - The MSR (Banked register) and MRS (Banked register) instructions.
 - The ERET instruction.

All other values are reserved.

In ARMv8-A the permitted values are:

- 0000 when EL2 is implemented.
- 0001 when EL2 is not implemented.

This field is only valid when the value of ID_PFR1.Virtualization is 0, otherwise it holds the value 0000.

———— **Note** —————

The ID_ISAR registers do not identify whether the instructions added by the ARMv7 Virtualization Extensions are implemented.

Sec_frac, bits [23:20]

Security fractional field. When the Security field is 0000, determines the support for features from the ARMv7 Security Extensions. Defined values are:

- 0000 No features from the ARMv7 Security Extensions are implemented.
- 0001 The following features from the ARMv7 Security Extensions are implemented:
 - The VBAR register.
 - The TTBCR.PD0 and TTBCR.PD1 bits.
- 0010 As for 0001, plus the ability to access Secure or Non-secure physical memory is supported.

All other values are reserved.

In ARMv8-A the permitted values are:

- 0000 when EL3 is implemented.
- 0001 or 0010 when EL3 is not implemented.

This field is only valid when the value of ID_PFR1.Security is 0, otherwise it holds the value 0000.

GenTimer, bits [19:16]

Generic Timer support. Defined values are:

- 0000 Not implemented.
- 0001 Generic Timer implemented.

All other values are reserved.

In ARMv8-A the only permitted value is 0001.

Virtualization, bits [15:12]

Virtualization support. Defined values are:

- 0000 EL2, Hyp mode, and the HVC instruction not implemented.
- 0001 EL2, Hyp mode, the HVC instruction, and all the features described by Virt_frac == 0001 implemented.

All other values are reserved.

In ARMv8-A the permitted values are:

- 0000 when EL2 is not implemented.
- 0001 when EL2 is implemented.

In an implementation that includes EL2, if EL2 cannot use AArch32 but EL1 can use AArch32 then this field has the value 0001.

———— **Note** —————

The ID_ISARs do not identify whether the HVC instruction is implemented.

MProgMod, bits [11:8]

M profile programmers' model support. Defined values are:

- 0000 Not supported.
- 0010 Support for two-stack programmers' model.

All other values are reserved.

In ARMv8-A the only permitted value is 0000.

Security, bits [7:4]

Security support. Defined values are:

- 0000 EL3, Monitor mode, and the SMC instruction not implemented.
- 0001 EL3, Monitor mode, the SMC instruction, and all the features described by Sec_frac == 0001 implemented.
- 0010 As for 0001, and adds the ability to set the NSACR.RFR bit. Not permitted in ARMv8 as the NSACR.RFR bit is RES0.

All other values are reserved.

In ARMv8-A the permitted values are:

- 0000 when EL3 is not implemented.
- 0001 when EL3 is implemented.

In an implementation that includes EL3, if EL3 cannot use AArch32 but EL1 can use AArch32 then this field has the value 0001.

ProgMod, bits [3:0]

Support for the standard programmers' model for ARMv4 and later. Model must support User, FIQ, IRQ, Supervisor, Abort, Undefined, and System modes. Defined values are:

- 0000 Not supported.
- 0001 Supported.

All other values are reserved.

In ARMv8-A the only permitted value is 0001.

Accessing the ID_PFR1

This register can be read using MRC with the following syntax:

MRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c0, c1, 1	000	001	0000	1111	0001

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	RO	n/a	RO
x	0	1	-	RO	RO	RO
x	1	1	-	n/a	RO	RO

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \&\& (HCR_EL2.E2H == 0)$:
 - If $HCR_EL2.TID3 == 1$, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If $HSTR_EL2.T0 == 1$, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \&\& (HCR_EL2.E2H == 1) \&\& (HCR_EL2.TGE == 0)$:
 - If $HCR_EL2.TID3 == 1$, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If $HSTR_EL2.T0 == 1$, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $HCR.TID3 == 1$, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
 - If $HSTR.T0 == 1$, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.

G6.2.93 IFAR, Instruction Fault Address Register

The IFAR characteristics are:

Purpose

Holds the virtual address of the faulting address that caused a synchronous Prefetch Abort exception.

Configurations

AArch32 System register IFAR(NS) is architecturally mapped to AArch64 System register [FAR_EL1](#)[63:32].

AArch32 System register IFAR(S) is architecturally mapped to AArch32 System register [HIFAR](#) when EL2 is implemented.

AArch32 System register IFAR(S) is architecturally mapped to AArch64 System register [FAR_EL2](#)[63:32] when EL2 is implemented.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

IFAR is a 32-bit register.

Field descriptions

The IFAR bit assignments are:

Bits [31:0]

VA of faulting address of synchronous Prefetch Abort exception.

Accessing the IFAR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c6, c0, 2	000	010	0110	1111	0000

Accessibility

The register is accessible in software as follows:

Configuration	Control			Accessibility				Instance
	E2H	TGE	NS	EL0	EL1	EL2	EL3	
EL3 is using AArch32.	x	x	0	-	n/a	n/a	RW	IFAR_s
EL3 is not implemented.	x	x	0	-	RW	n/a	n/a	IFAR
EL3 is not implemented.	x	0	1	-	RW	RW	n/a	IFAR
EL3 is not implemented.	x	1	1	-	n/a	RW	n/a	IFAR
EL3 is using AArch64.	x	x	0	-	RW	n/a	n/a	IFAR
EL3 is using AArch64.	x	0	1	-	RW	RW	n/a	IFAR
EL3 is using AArch64.	x	1	1	-	n/a	RW	n/a	IFAR
EL3 is using AArch32.	x	0	1	-	RW	RW	RW	IFAR_ns
EL3 is using AArch32.	x	1	1	-	n/a	RW	RW	IFAR_ns

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If HCR_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
 - If HCR_EL2.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If HSTR_EL2.T6==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If HCR_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
 - If HCR_EL2.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If HSTR_EL2.T6==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HCR.TVM==1, Non-secure write accesses to this register from EL1 are trapped to Hyp mode.
 - If HCR.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
 - If HSTR.T6==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

G6.2.94 IFSR, Instruction Fault Status Register

The IFSR characteristics are:

Purpose

Holds status information about the last instruction fault.

Configurations

AArch32 System register IFSR is architecturally mapped to AArch64 System register [IFSR32_EL2](#).

The current translation table format determines which format of the register is used.

RW fields in this register reset to architecturally UNKNOWN values.

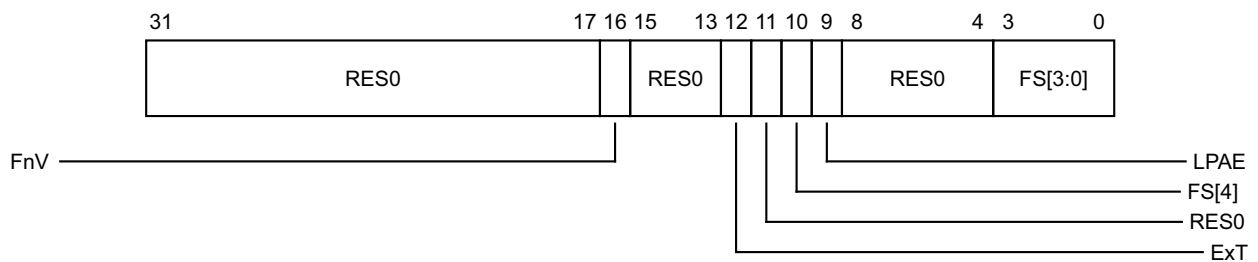

Attributes

IFSR is a 32-bit register.

Field descriptions

The IFSR bit assignments are:

When *TTBCR.EAE*==0:

Bits [31:17]

Reserved, RES0.

FnV, bit [16]

FAR not Valid, for a Synchronous external abort other than a Synchronous external abort on a translation table walk.

0 [IFAR](#) is valid.

1 [IFAR](#) is not valid, and holds an UNKNOWN value.

This field is only valid for a Synchronous external abort other than a Synchronous external abort on a translation table walk. It is RES0 for all other Prefetch Abort exceptions.

Bits [15:13]

Reserved, RES0.

ExT, bit [12]

External abort type. This bit can be used to provide an IMPLEMENTATION DEFINED classification of external aborts.

In an implementation that does not provide any classification of external aborts, this bit is RES0.

For aborts other than external aborts this bit always returns 0.

Bit [11]

Reserved, RES0.

FS[4], bit [10]

See FS[3:0], bits [3:0] for description of the FS field.

LPAE, bit [9]

On taking a Data Abort exception, this bit is set as follows:

- 0 Using the Short-descriptor translation table formats.
- 1 Using the Long-descriptor translation table formats.

Hardware does not interpret this bit to determine the behavior of the memory system, and therefore software can set this bit to 0 or 1 without affecting operation.

Bits [8:4]

Reserved, RES0.

FS[3:0], bits [3:0]

Fault status bits. Interpreted with bit [10]. Possible values of FS[4:0] are:

- 00001 PC alignment fault
- 00010 Debug exception
- 00011 Access flag fault, level 1
- 00101 Translation fault, level 1
- 00110 Access flag fault, level 2
- 00111 Translation fault, level 2
- 01000 Synchronous external abort, not on translation table walk
- 01001 Domain fault, level 1
- 01011 Domain fault, level 2
- 01100 Synchronous external abort, on translation table walk, level 1
- 01101 Permission fault, level 1
- 01110 Synchronous external abort, on translation table walk, level 2
- 01111 Permission fault, level 2
- 10000 TLB conflict abort
- 10100 IMPLEMENTATION DEFINED fault (Lockdown fault)
- 11001 Synchronous parity or ECC error on memory access, not on translation table walk
- 11100 Synchronous parity or ECC error on translation table walk, level 1
- 11110 Synchronous parity or ECC error on translation table walk, level 2

All other values are reserved.

When the RAS Extension is implemented, 11001, 11100, and 11110 are reserved.

For more information about the lookup level associated with a fault, see [The level associated with MMU faults on a Short-descriptor translation table lookup](#) on page G4-4669.

When TTBCR.EAE==1:

Bits [31:17]

Reserved, RES0.

FnV, bit [16]

FAR not Valid, for a Synchronous external abort other than a Synchronous external abort on a translation table walk.

0 **IFAR** is valid.

1 **IFAR** is not valid, and holds an UNKNOWN value.

This field is only valid for a Synchronous external abort other than a Synchronous external abort on a translation table walk. It is RES0 for all other Prefetch Abort exceptions.

Bits [15:13]

Reserved, RES0.

ExT, bit [12]

External abort type. This bit can be used to provide an IMPLEMENTATION DEFINED classification of external aborts.

In an implementation that does not provide any classification of external aborts, this bit is RES0.

For aborts other than external aborts this bit always returns 0.

Bits [11:10]

Reserved, RES0.

LPAE, bit [9]

On taking a Data Abort exception, this bit is set as follows:

0 Using the Short-descriptor translation table formats.

1 Using the Long-descriptor translation table formats.

Hardware does not interpret this bit to determine the behavior of the memory system, and therefore software can set this bit to 0 or 1 without affecting operation.

Bits [8:6]

Reserved, RES0.

STATUS, bits [5:0]

Fault status bits. Possible values of this field are:

000000	Address size fault in TTBR0 or TTBR1
000001	Address size fault, level 1
000010	Address size fault, level 2
000011	Address size fault, level 3
000101	Translation fault, level 1
000110	Translation fault, level 2
000111	Translation fault, level 3
001001	Access flag fault, level 1
001010	Access flag fault, level 2
001011	Access flag fault, level 3
001101	Permission fault, level 1
001110	Permission fault, level 2
001111	Permission fault, level 3
010000	Synchronous external abort, not on translation table walk
010101	Synchronous external abort, on translation table walk, level 1

- 010110 Synchronous external abort, on translation table walk, level 2
- 010111 Synchronous external abort, on translation table walk, level 3
- 011000 Synchronous parity or ECC error on memory access, not on translation table walk
- 011101 Synchronous parity or ECC error on memory access on translation table walk, level 1
- 011110 Synchronous parity or ECC error on memory access on translation table walk, level 2
- 011111 Synchronous parity or ECC error on memory access on translation table walk, level 3
- 100001 PC alignment fault
- 100010 Debug exception
- 110000 TLB conflict abort

All other values are reserved.

When the RAS Extension is implemented, 011000, 011101, 011110, and 011111 are reserved.

For more information about the lookup level associated with a fault, see [The level associated with MMU faults on a Long-descriptor translation table lookup on page G4-4671](#).

Accessing the IFSR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c5, c0, 1	000	001	0101	1111	0000

Accessibility

The register is accessible in software as follows:

Configuration	Control			Accessibility				Instance
	E2H	TGE	NS	EL0	EL1	EL2	EL3	
EL3 is not implemented.	x	x	0	-	RW	n/a	n/a	IFSR
EL3 is not implemented.	x	0	1	-	RW	RW	n/a	IFSR
EL3 is not implemented.	x	1	1	-	n/a	RW	n/a	IFSR
EL3 is using AArch64.	x	x	0	-	RW	n/a	n/a	IFSR
EL3 is using AArch64.	x	0	1	-	RW	RW	n/a	IFSR
EL3 is using AArch64.	x	1	1	-	n/a	RW	n/a	IFSR
EL3 is using AArch32.	x	x	0	-	n/a	n/a	RW	IFSR_s
EL3 is using AArch32.	x	0	1	-	RW	RW	RW	IFSR_ns
EL3 is using AArch32.	x	1	1	-	n/a	RW	RW	IFSR_ns

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 0)$:
 - If $HCR_EL2.TVM == 1$, Non-secure write accesses to this register from EL1 are trapped to EL2.
 - If $HCR_EL2.TRVM == 1$, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If $HSTR_EL2.T5 == 1$, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 1) \ \&\& \ (HCR_EL2.TGE == 0)$:
 - If $HCR_EL2.TVM == 1$, Non-secure write accesses to this register from EL1 are trapped to EL2.
 - If $HCR_EL2.TRVM == 1$, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If $HSTR_EL2.T5 == 1$, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $HCR.TVM == 1$, Non-secure write accesses to this register from EL1 are trapped to Hyp mode.
 - If $HCR.TRVM == 1$, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
 - If $HSTR.T5 == 1$, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

G6.2.95 ISR, Interrupt Status Register

The ISR characteristics are:

Purpose

Shows whether any IRQ, FIQ, or external abort is pending. In an implementation that includes EL2, when the register is accessed from Non-secure EL1, a pending interrupt might be a physical interrupt or a virtual interrupt, and the architecture does not provide any mechanism that software executing at Non-secure EL1 can use to determine whether a pending interrupt is physical or virtual. For all other accesses, any indicated interrupt must be a physical interrupt.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register ISR is architecturally mapped to AArch64 System register [ISR_EL1](#).

Attributes

ISR is a 32-bit register.

Field descriptions

The ISR bit assignments are:

Bits [31:9]

Reserved, RES0.

A, bit [8]

Asynchronous external abort pending bit:

0 No pending asynchronous external abort.

1 An asynchronous external abort is pending.

I, bit [7]

IRQ pending bit. Indicates whether an IRQ interrupt is pending:

0 No pending IRQ.

1 An IRQ interrupt is pending.

F, bit [6]

FIQ pending bit. Indicates whether an FIQ interrupt is pending.

0 No pending FIQ.

1 An FIQ interrupt is pending.

Bits [5:0]

Reserved, RES0.

Accessing the ISR

This register can be read using MRC with the following syntax:

MRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c12, c1, 0	000	000	1100	1111	0001

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	RO	n/a	RO
x	0	1	-	RO	RO	RO
x	1	1	-	n/a	RO	RO

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If HSTR_EL2.T12==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If HSTR_EL2.T12==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HSTR.T12==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.

G6.2.96 ITLBIALL, Instruction TLB Invalidate All

The ITLBIALL characteristics are:

Purpose

Invalidate all cached copies of translation table entries from instruction TLBs that are from any level of the translation table walk. The entries that are invalidated are as follows:

- If executed at Secure EL1 when EL3 is using AArch64, all entries that would be required for the Secure EL1&0 translation regime.
- If executed in Secure state when EL3 is using AArch32, all entries that would be required for the Secure PL1&0 translation regime.
- If executed at Non-secure EL1, all stage 1 translation table entries that would be required for the Non-secure PL1&0 translation regime and, if EL2 is implemented, they must match the current VMID.
- If executed at EL2, the stage 1 or stage 2 translation table entries that would be required for the Non-secure PL1&0 translation regime and matches the current VMID.

The invalidation only applies to the PE that executes this instruction.

ARM deprecates the use of this instruction. It is only provided for backwards compatibility with earlier versions of the ARM architecture.

Configurations

There are no configuration notes.

Attributes

ITLBIALL is a 32-bit System instruction.

Field descriptions

ITLBIALL ignores the value in the register specified by the instruction. Software does not have to write a value to the register before issuing this instruction.

Executing the ITLBIALL instruction

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c8, c5, 0	000	000	1000	1111	0101

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	WO	n/a	WO
x	0	1	-	WO	WO	WO
x	1	1	-	n/a	WO	WO

When `HCR.FB` is 1, at Non-secure EL1 this instruction executes as a `TLBIALLS` operating on instruction TLBs only.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and `(SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0)`:
 - If `HCR_EL2.TTLB==1`, Non-secure execution of this instruction at EL1 is trapped to EL2.
 - If `HSTR_EL2.T8==1`, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and `(SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0)`:
 - If `HCR_EL2.TTLB==1`, Non-secure execution of this instruction at EL1 is trapped to EL2.
 - If `HSTR_EL2.T8==1`, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and `SCR_EL3.NS == 1`:
 - If `HCR.TTLB==1`, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
 - If `HSTR.T8==1`, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

G6.2.97 ITLBIASID, Instruction TLB Invalidate by ASID match

The ITLBIASID characteristics are:

Purpose

Invalidate all cached copies of translation table entries from instruction TLBs that meet the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used for the specified ASID, and either:
 - Is from a level of lookup above the final level.
 - Is a non-global entry from the final level of lookup.
- If EL2 is implemented, the entry would be used with the current VMID.

From the entries that match these requirement, the entries that are invalidated are required for the following translation regime:

- If executed at Secure EL1 when EL3 is using AArch64, the Secure EL1&0 translation regime.
- If executed in Secure state when EL3 is using AArch32, the Secure PL1&0 translation regime.
- If executed in Non-secure state, the Non-secure PL1&0 translation regime.

The invalidation only applies to the PE that executes this instruction.

ARM deprecates the use of this instruction. It is only provided for backwards compatibility with earlier versions of the ARM architecture.

Configurations

There are no configuration notes.

Attributes

ITLBIASID is a 32-bit System instruction.

Field descriptions

The ITLBIASID input value bit assignments are:

Bits [31:8]

Reserved, RES0.

ASID, bits [7:0]

ASID value to match. Any TLB entries for non-global pages that match the ASID values will be affected by this operation.

Executing the ITLBIASID instruction

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c8, c5, 2	000	010	1000	1111	0101

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	WO	n/a	WO
x	0	1	-	WO	WO	WO
x	1	1	-	n/a	WO	WO

When `HCR.FB` is 1, at Non-secure EL1 this instruction executes as a `TLBIASIDIS` operating on instruction TLBs only.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 0)$:
 - If `HCR_EL2.TTLB==1`, Non-secure execution of this instruction at EL1 is trapped to EL2.
 - If `HSTR_EL2.T8==1`, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 1) \ \&\& \ (HCR_EL2.TGE == 0)$:
 - If `HCR_EL2.TTLB==1`, Non-secure execution of this instruction at EL1 is trapped to EL2.
 - If `HSTR_EL2.T8==1`, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If `HCR.TTLB==1`, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
 - If `HSTR.T8==1`, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

G6.2.98 ITLBIMVA, Instruction TLB Invalidate by VA

The ITLBIMVA characteristics are:

Purpose

Invalidate all cached copies of translation table entries from instruction TLBs that meet the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified address, and one of the following applies:
 - The entry is from a level of lookup above the final level and matches the specified ASID.
 - The entry is a global entry from the final level of lookup.
 - The entry is a non-global entry from the final level of lookup that matches the specified ASID.
- If EL2 is implemented, the entry would be used with the current VMID.

From the entries that match these requirement, the entries that are invalidated are required for the following translation regime:

- If executed at Secure EL1 when EL3 is using AArch64, the Secure EL1&0 translation regime.
- If executed in Secure state when EL3 is using AArch32, the Secure PL1&0 translation regime.
- If executed in Non-secure state, the Non-secure PL1&0 translation regime.

The invalidation only applies to the PE that executes this instruction.

ARM deprecates the use of this instruction. It is only provided for backwards compatibility with earlier versions of the ARM architecture.

Configurations

There are no configuration notes.

Attributes

ITLBIMVA is a 32-bit System instruction.

Field descriptions

The ITLBIMVA input value bit assignments are:

VA, bits [31:12]

Virtual address to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Bits [11:8]

Reserved, RES0.

ASID, bits [7:0]

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Global TLB entries that match the VA value will be affected by this operation, regardless of the value of the ASID field.

Executing the ITLBIMVA instruction

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c8, c5, 1	000	001	1000	1111	0101

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	WO	n/a	WO
x	0	1	-	WO	WO	WO
x	1	1	-	n/a	WO	WO

When `HCR.FB` is 1, at Non-secure EL1 this instruction executes as a `TLBIMVAIS` operating on instruction TLBs only.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 0)$:
 - If $HCR_EL2.TTLB == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
 - If $HSTR_EL2.T8 == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 1) \ \&\& \ (HCR_EL2.TGE == 0)$:
 - If $HCR_EL2.TTLB == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
 - If $HSTR_EL2.T8 == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $HCR.TTLB == 1$, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
 - If $HSTR.T8 == 1$, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

G6.2.99 JIDR, Jazelle ID Register

The JIDR characteristics are:

Purpose

A Jazelle register, which identified the Jazelle architecture version.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

Attributes

JIDR is a 32-bit register.

Field descriptions

The JIDR bit assignments are:

Bits [31:0]

RAZ.

Accessing the JIDR

This register can be read using MRC with the following syntax:

MRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p14, 7, <Rt>, c0, c0, 0	111	000	0000	1110	0000

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	IMPLEMENTATION DEFINED	RO	n/a	RO
x	0	1	IMPLEMENTATION DEFINED	RO	RO	RO
x	1	1	IMPLEMENTATION DEFINED	n/a	RO	RO

For accesses from EL0 it is IMPLEMENTATION DEFINED whether the register is RO or UNDEFINED.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \&\& (HCR_EL2.E2H == 0)$:
 - If $HCR_EL2.TID0 == 1$, Non-secure read accesses to this register from EL0 and EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \&\& (HCR_EL2.E2H == 1) \&\& (HCR_EL2.TGE == 0)$:
 - If $HCR_EL2.TID0 == 1$, Non-secure read accesses to this register from EL0 and EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $HCR.TID0 == 1$, Non-secure read accesses to this register from EL0 and EL1 are trapped to Hyp mode.

G6.2.100 JMCR, Jazelle Main Configuration Register

The JMCR characteristics are:

Purpose

A Jazelle register, which provides control of the Jazelle extension.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

Attributes

JMCR is a 32-bit register.

Field descriptions

The JMCR bit assignments are:

Bits [31:0]

RAZ/WI.

Accessing the JMCR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p14, 7, <Rt>, c2, c0, 0	111	000	0010	1110	0000

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	IMPLEMENTATION DEFINED	RW	n/a	RW
x	0	1	IMPLEMENTATION DEFINED	RW	RW	RW
x	1	1	IMPLEMENTATION DEFINED	n/a	RW	RW

For accesses from EL0 it is IMPLEMENTATION DEFINED whether the register is RW or UNDEFINED.

G6.2.101 JOSCR, Jazelle OS Control Register

The JOSCR characteristics are:

Purpose

A Jazelle register, which provides operating system control of the Jazelle Extension.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

Attributes

JOSCR is a 32-bit register.

Field descriptions

The JOSCR bit assignments are:

Bits [31:0]

RAZ/WI.

Accessing the JOSCR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p14, 7, <Rt>, c1, c0, 0	111	000	0001	1110	0000

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	IMPLEMENTATION DEFINED	RW	n/a	RW
x	0	1	IMPLEMENTATION DEFINED	RW	RW	RW
x	1	1	IMPLEMENTATION DEFINED	n/a	RW	RW

For accesses from EL0 it is IMPLEMENTATION DEFINED whether the register is RW or UNDEFINED.

G6.2.102 MAIRO, Memory Attribute Indirection Register 0

The MAIRO characteristics are:

Purpose

Along with MAIR1, provides the memory attribute encodings corresponding to the possible AttrIdx values in a Long-descriptor format translation table entry for stage 1 translations.

AttrIdx[2] indicates the MAIR register to be used:

- When AttrIdx[2] is 0, MAIRO is used.
- When AttrIdx[2] is 1, MAIR1 is used.

Configurations

AArch32 System register MAIRO is architecturally mapped to AArch64 System register MAIR_ELI[31:0].

MAIRO and PRRR are the same register, with a different view depending on the value of TTBCR.EAE:

- When it is set to 0, the register is as described in PRRR.
- When it is set to 1, the register is as described in MAIRO.

When EL3 is using AArch32, write access to MAIRO(S) is disabled when the CP15SSDISABLE signal is asserted HIGH.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

MAIRO is a 32-bit register.

Field descriptions

The MAIRO bit assignments are:

When TTBCR.EAE==1:

Attr<n>, bits [8n+7:8n], for n = 0 to 3

The memory attribute encoding for an AttrIdx[2:0] entry in a Long descriptor format translation table entry, where:

- AttrIdx[2:0] gives the value of <n> in Attr<n>.
- AttrIdx[2] defines which MAIR to access. Attr7 to Attr4 are in MAIR1, and Attr3 to Attr0 are in MAIRO.

Bits [7:4] are encoded as follows:

Attr<n>[7:4]	Meaning
0000	Device memory. See encoding of Attr<n>[3:0] for the type of Device memory.
00RW, RW not 00	Normal memory, Outer Write-Through Transient
0100	Normal memory, Outer Non-cacheable

Attr<n>[7:4]	Meaning
01RW, RW not 00	Normal memory, Outer Write-Back Transient
10RW	Normal memory, Outer Write-Through Non-transient
11RW	Normal memory, Outer Write-Back Non-transient

R = Outer Read-Allocate policy, W = Outer Write-Allocate policy.

The meaning of bits [3:0] depends on the value of bits [7:4]:

Attr<n>[3:0]	Meaning when Attr<n>[7:4] is 0000	Meaning when Attr<n>[7:4] is not 0000
0000	Device-nGnRnE memory	UNPREDICTABLE
00RW, RW not 00	UNPREDICTABLE	Normal memory, Inner Write-Through Transient
0100	Device-nGnRE memory	Normal memory, Inner Non-cacheable
01RW, RW not 00	UNPREDICTABLE	Normal memory, Inner Write-Back Transient
1000	Device-nGRE memory	Normal memory, Inner Write-Through Non-transient (RW=00)
10RW, RW not 00	UNPREDICTABLE	Normal memory, Inner Write-Through Non-transient
1100	Device-GRE memory	Normal memory, Inner Write-Back Non-transient (RW=00)
11RW, RW not 00	UNPREDICTABLE	Normal memory, Inner Write-Back Non-transient

R = Inner Read-Allocate policy, W = Inner Write-Allocate policy.

The R and W bits in some Attr<n> fields have the following meanings:

R or W	Meaning
0	No Allocate
1	Allocate

Accessing the MAIR0

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c10, c2, 0	000	000	1010	1111	0010

Accessibility

The register is accessible in software as follows:

Configuration	Control			Accessibility				Instance
	E2H	TGE	NS	EL0	EL1	EL2	EL3	
EL3 is using AArch32.	x	x	0	-	n/a	n/a	RW	MAIR0_s
EL3 is not implemented.	x	x	0	-	RW	n/a	n/a	MAIR0
EL3 is not implemented.	x	0	1	-	RW	RW	n/a	MAIR0
EL3 is not implemented.	x	1	1	-	n/a	RW	n/a	MAIR0
EL3 is using AArch64.	x	x	0	-	RW	n/a	n/a	MAIR0
EL3 is using AArch64.	x	0	1	-	RW	RW	n/a	MAIR0
EL3 is using AArch64.	x	1	1	-	n/a	RW	n/a	MAIR0
EL3 is using AArch32.	x	0	1	-	RW	RW	RW	MAIR0_ns
EL3 is using AArch32.	x	1	1	-	n/a	RW	RW	MAIR0_ns

When EL3 is using AArch32, write access to MAIR0_s is UNDEFINED when the CP15SSDISABLE signal is asserted HIGH.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If HCR_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
 - If HCR_EL2.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If HSTR_EL2.T10==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If HCR_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
 - If HCR_EL2.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If HSTR_EL2.T10==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HCR.TVM==1, Non-secure write accesses to this register from EL1 are trapped to Hyp mode.
 - If HCR.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
 - If HSTR.T10==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

G6.2.103 MAIR1, Memory Attribute Indirection Register 1

The MAIR1 characteristics are:

Purpose

Along with MAIR0, provides the memory attribute encodings corresponding to the possible AttrIdx values in a Long-descriptor format translation table entry for stage 1 translations.

AttrIdx[2] indicates the MAIR register to be used:

- When AttrIdx[2] is 0, MAIR0 is used.
- When AttrIdx[2] is 1, MAIR1 is used.

Configurations

AArch32 System register MAIR1 is architecturally mapped to AArch64 System register MAIR_EL1[63:32].

MAIR1 and NMRR are the same register, with a different view depending on the value of TTBCR.EAE:

- When it is set to 0, the register is as described in NMRR.
- When it is set to 1, the register is as described in MAIR1.

When EL3 is using AArch32, write access to MAIR1(S) is disabled when the CP15SSDISABLE signal is asserted HIGH.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

MAIR1 is a 32-bit register.

Field descriptions

The MAIR1 bit assignments are:

When TTBCR.EAE==1:

Attr<n>, bits [8(n-4)+7:8(n-4)], for n = 4 to 7

The memory attribute encoding for an AttrIdx[2:0] entry in a Long descriptor format translation table entry, where:

- AttrIdx[2:0] gives the value of <n> in Attr<n>.
- AttrIdx[2] defines which MAIR to access. Attr7 to Attr4 are in MAIR1, and Attr3 to Attr0 are in MAIR0.

Bits [7:4] are encoded as follows:

Attr<n>[7:4]	Meaning
0000	Device memory. See encoding of Attr<n>[3:0] for the type of Device memory.
00RW, RW not 00	Normal memory, Outer Write-Through Transient
0100	Normal memory, Outer Non-cacheable

Attr<n>[7:4]	Meaning
01RW, RW not 00	Normal memory, Outer Write-Back Transient
10RW	Normal memory, Outer Write-Through Non-transient
11RW	Normal memory, Outer Write-Back Non-transient

R = Outer Read-Allocate policy, W = Outer Write-Allocate policy.

The meaning of bits [3:0] depends on the value of bits [7:4]:

Attr<n>[3:0]	Meaning when Attr<n>[7:4] is 0000	Meaning when Attr<n>[7:4] is not 0000
0000	Device-nGnRnE memory	UNPREDICTABLE
00RW, RW not 00	UNPREDICTABLE	Normal memory, Inner Write-Through Transient
0100	Device-nGnRE memory	Normal memory, Inner Non-cacheable
01RW, RW not 00	UNPREDICTABLE	Normal memory, Inner Write-Back Transient
1000	Device-nGRE memory	Normal memory, Inner Write-Through Non-transient (RW=00)
10RW, RW not 00	UNPREDICTABLE	Normal memory, Inner Write-Through Non-transient
1100	Device-GRE memory	Normal memory, Inner Write-Back Non-transient (RW=00)
11RW, RW not 00	UNPREDICTABLE	Normal memory, Inner Write-Back Non-transient

R = Inner Read-Allocate policy, W = Inner Write-Allocate policy.

The R and W bits in some Attr<n> fields have the following meanings:

R or W	Meaning
0	No Allocate
1	Allocate

Accessing the MAIR1

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c10, c2, 1	000	001	1010	1111	0010

Accessibility

The register is accessible in software as follows:

Configuration	Control			Accessibility				Instance
	E2H	TGE	NS	EL0	EL1	EL2	EL3	
EL3 is using AArch32.	x	x	0	-	n/a	n/a	RW	MAIR1_s
EL3 is using AArch32.	x	0	1	-	RW	RW	RW	MAIR1_ns
EL3 is using AArch32.	x	1	1	-	n/a	RW	RW	MAIR1_ns
EL3 is not implemented.	x	x	0	-	RW	n/a	n/a	MAIR1
EL3 is not implemented.	x	0	1	-	RW	RW	n/a	MAIR1
EL3 is not implemented.	x	1	1	-	n/a	RW	n/a	MAIR1
EL3 is using AArch64.	x	x	0	-	RW	n/a	n/a	MAIR1
EL3 is using AArch64.	x	0	1	-	RW	RW	n/a	MAIR1
EL3 is using AArch64.	x	1	1	-	n/a	RW	n/a	MAIR1

When EL3 is using AArch32, write access to MAIR1_s is UNDEFINED when the CP15SSDISABLE signal is asserted HIGH.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If HCR_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
 - If HCR_EL2.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If HSTR_EL2.T10==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If HCR_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
 - If HCR_EL2.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If HSTR_EL2.T10==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HCR.TVM==1, Non-secure write accesses to this register from EL1 are trapped to Hyp mode.
 - If HCR.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
 - If HSTR.T10==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

G6.2.104 MIDR, Main ID Register

The MIDR characteristics are:

Purpose

Provides identification information for the PE, including an implementer code for the device and a device ID number.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register MIDR is architecturally mapped to AArch64 System register [MIDR_EL1](#).

AArch32 System register MIDR is architecturally mapped to External register [MIDR_EL1](#).

Some fields of the MIDR are IMPLEMENTATION DEFINED. For details of the values of these fields for a particular ARMv8 implementation, and any implementation-specific significance of these values, see the product documentation.

Attributes

MIDR is a 32-bit register.

Field descriptions

The MIDR bit assignments are:

Implementer, bits [31:24]

The Implementer code. This field must hold an implementer code that has been assigned by ARM. Assigned codes include the following:

Hex representation	ASCII representation	Implementer
0x41	A	ARM Limited
0x42	B	Broadcom Corporation
0x43	C	Cavium Inc.
0x44	D	Digital Equipment Corporation
0x49	I	Infineon Technologies AG
0x4D	M	Motorola or Freescale Semiconductor Inc.
0x4E	N	NVIDIA Corporation
0x50	P	Applied Micro Circuits Corporation
0x51	Q	Qualcomm Inc.
0x56	V	Marvell International Ltd.
0x69	i	Intel Corporation

ARM can assign codes that are not published in this manual. All values not assigned by ARM are reserved and must not be used.

Variant, bits [23:20]

An IMPLEMENTATION DEFINED variant number. Typically, this field is used to distinguish between different product variants, or major revisions of a product.

Architecture, bits [19:16]

The permitted values of this field are:

0001	ARMv4
0010	ARMv4T
0011	ARMv5 (obsolete)
0100	ARMv5T
0101	ARMv5TE
0110	ARMv5TEJ
0111	ARMv6
1111	Architectural features are individually identified in the ID_* registers, see <i>Identification registers, functional group</i> on page G4-4727.

All other values are reserved.

PartNum, bits [15:4]

An IMPLEMENTATION DEFINED primary part number for the device.

On processors implemented by ARM, if the top four bits of the primary part number are 0x0 or 0x7, the variant and architecture are encoded differently.

Revision, bits [3:0]

An IMPLEMENTATION DEFINED revision number for the device.

Accessing the MIDR

This register can be read using MRC with the following syntax:

MRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c0, c0, 0	000	000	0000	1111	0000

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	RO	n/a	RO
x	0	1	-	RO	RO	RO
x	1	1	-	n/a	RO	RO

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 0)$:
 - If $HSTR_EL2.T0 == 1$, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 1) \ \&\& \ (HCR_EL2.TGE == 0)$:
 - If $HSTR_EL2.T0 == 1$, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $HSTR.T0 == 1$, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.

G6.2.105 MPIDR, Multiprocessor Affinity Register

The MPIDR characteristics are:

Purpose

In a multiprocessor system, provides an additional PE identification mechanism for scheduling purposes.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register MPIDR is architecturally mapped to AArch64 System register [MPIDR_EL1](#).

The assigned value of the MPIDR. {Aff2, Aff1, Aff0} or [MPIDR_EL1](#). {Aff3, Aff2, Aff1, Aff0} set of fields of each PE must be unique within the system as a whole.

In a uniprocessor system ARM recommends that each Aff<n> field of this register returns a value of 0.

Attributes

MPIDR is a 32-bit register.

Field descriptions

The MPIDR bit assignments are:

M, bit [31]

Indicates whether this implementation includes the functionality introduced by the ARMv7 Multiprocessing Extensions. The possible values of this bit are:

- 0 This implementation does not include the ARMv7 Multiprocessing Extensions functionality.
- 1 This implementation includes the ARMv7 Multiprocessing Extensions functionality.

In ARMv8 this bit is RES1.

U, bit [30]

Indicates a Uniprocessor system, as distinct from PE 0 in a multiprocessor system. The possible values of this bit are:

- 0 Processor is part of a multiprocessor system.
- 1 Processor is part of a uniprocessor system.

Bits [29:25]

Reserved, RES0.

MT, bit [24]

Indicates whether the lowest level of affinity consists of logical PEs that are implemented using a multithreading type approach. The possible values of this bit are:

- 0 Performance of PEs at the lowest affinity level is largely independent.
- 1 Performance of PEs at the lowest affinity level is very interdependent.

Aff2, bits [23:16]

Affinity level 2. The least significant affinity level field, for this PE in the system.

Aff1, bits [15:8]

Affinity level 1. The intermediate affinity level field, for this PE in the system.

Aff0, bits [7:0]

Affinity level 0. The most significant affinity level field, for this PE in the system.

Accessing the MPIDR

This register can be read using MRC with the following syntax:

MRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c0, c0, 5	000	101	0000	1111	0000

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	RO	n/a	RO
x	0	1	-	RO	RO	RO
x	1	1	-	n/a	RO	RO

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HSTR.T0==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.

G6.2.106 MVBAR, Monitor Vector Base Address Register

The MVBAR characteristics are:

Purpose

When EL3 is implemented and can use AArch32, holds the vector base address for any exception that is taken to Monitor mode.

Secure software must program the MVBAR with the required initial value as part of the PE boot sequence.

Configurations

This register is only accessible in Secure state.

It is IMPLEMENTATION DEFINED whether MVBAR[0] has a fixed value and ignored writes, or takes the last value written to it.

Write access to MVBAR is disabled when the CP15SSDISABLE signal is asserted HIGH.

On a reset into EL3 using AArch32, the reset value of MVBAR is an IMPLEMENTATION DEFINED choice between:

- MVBAR[31:5] = an IMPLEMENTATION DEFINED value, which might be UNKNOWN.
- MVBAR[4:1] = RES0.
- MVBAR[0] = 0.

And:

- MVBAR[31:1] = an IMPLEMENTATION DEFINED value that is bits[31:1] of the AArch32 reset address.
- MVBAR[0] = 1.

Attributes

MVBAR is a 32-bit register.

Field descriptions

The MVBAR bit assignments are:

When programmed with a vector base address:

Bits [31:5]

Vector Base Address. Bits[31:5] of the base address of the exception vectors for exceptions taken to this Exception level. Bits[4:0] of an exception vector are the exception offset.

Reserved, bits [4:0]

Reserved, see Configurations.

Accessing the MVBAR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c12, c0, 1	000	001	1100	1111	0000

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	RW
x	0	1	-	-	-	RW
x	1	1	-	n/a	-	RW

When EL3 is using AArch32, write access to MVBAR is UNDEFINED when the CP15SSDISABLE signal is asserted HIGH.

If EL3 is implemented and is using AArch64, any read or write to MVBAR from Secure EL1 using AArch32 is trapped as an exception to EL3.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If HSTR_EL2.T12==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If HSTR_EL2.T12==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HSTR.T12==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

G6.2.107 MVFR0, Media and VFP Feature Register 0

The MVFR0 characteristics are:

Purpose

Describes the features provided by the AArch32 Advanced SIMD and Floating-point implementation.

Must be interpreted with [MVFR1](#) and [MVFR2](#).

For general information about the interpretation of the ID registers see [Principles of the ID scheme for fields in ID registers on page G4-4701](#).

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register MVFR0 is architecturally mapped to AArch64 System register [MVFR0_EL1](#).

Implemented only if the implementation includes Advanced SIMD and floating-point instructions.

Attributes

MVFR0 is a 32-bit register.

Field descriptions

The MVFR0 bit assignments are:

31	28 27	24 23	20 19	16 15	12 11	8 7	4 3	0
FPRound	FPShVec	FPSqrt	FPDivide	FPTrap	FPDP	FPSP	SIMDReg	

FPRound, bits [31:28]

Floating-Point Rounding modes. Indicates whether the floating-point implementation provides support for rounding modes. Defined values are:

0000 Not implemented, or only Round to Nearest mode supported, except that Round towards Zero mode is supported for VCVT instructions that always use that rounding mode regardless of the [FPSCR](#) setting.

0001 All rounding modes supported.

All other values are reserved.

In ARMv8-A the permitted values are 0000 and 0001.

FPShVec, bits [27:24]

Short Vectors. Indicates whether the floating-point implementation provides support for the use of short vectors. Defined values are:

0000 Short vectors not supported.

0001 Short vector operation supported.

All other values are reserved.

In ARMv8-A the only permitted value is 0000.

FPSqrt, bits [23:20]

Square Root. Indicates whether the floating-point implementation provides support for the ARMv6 VFP square root operations. Defined values are:

0000 Not supported in hardware.

0001 Supported.

All other values are reserved.

In ARMv8-A the permitted values are 0000 and 0001.

The VSQRT.F32 instruction also requires the single-precision floating-point attribute, bits [7:4], and the VSQRT.F64 instruction also requires the double-precision floating-point attribute, bits [11:8].

FPDivide, bits [19:16]

Indicates whether the floating-point implementation provides support for VFP divide operations. Defined values are:

0000 Not supported in hardware.

0001 Supported.

All other values are reserved.

In ARMv8-A the permitted values are 0000 and 0001.

The VDIV.F32 instruction also requires the single-precision floating-point attribute, bits [7:4], and the VDIV.F64 instruction also requires the double-precision floating-point attribute, bits [11:8].

FPTrap, bits [15:12]

Floating Point Exception Trapping. Indicates whether the floating-point implementation provides support for exception trapping. Defined values are:

0000 Not supported.

0001 Supported.

All other values are reserved.

A value of 0001 indicates that, when the corresponding trap is enabled, a floating-point exception generates an exception.

FPDP, bits [11:8]

Double Precision. Indicates whether the floating-point implementation provides support for double-precision operations. Defined values are:

0000 Not supported in hardware.

0001 Supported, VFPv2.

0010 Supported, VFPv3, VFPv4, or ARMv8. VFPv3 and ARMv8 add an instruction to load a double-precision floating-point constant, and conversions between double-precision and fixed-point values.

All other values are reserved.

In ARMv8-A the permitted values are 0000 and 0010.

A value of 0b0001 or 0b0010 indicates support for all VFP double-precision instructions in the supported version of VFP, except that, in addition to this field being nonzero:

- VSQRT.F64 is only available if the Square root field is 0001.
- VDIV.F64 is only available if the Divide field is 0001.
- Conversion between double-precision and single-precision is only available if the single-precision field is nonzero.

FPSP, bits [7:4]

Single Precision. Indicates whether the floating-point implementation provides support for single-precision operations. Defined values are:

0000 Not supported in hardware.

0001 Supported, VFPv2.

0010 Supported, VFPv3 or VFPv4. VFPv3 adds an instruction to load a single-precision floating-point constant, and conversions between single-precision and fixed-point values.

All other values are reserved.

In ARMv8-A the permitted values are 0000 and 0010.

A value of 0b0001 or 0b0010 indicates support for all VFP single-precision instructions in the supported version of VFP, except that, in addition to this field being nonzero:

- VSQRT.F32 is only available if the Square root field is 0001.
- VDIV.F32 is only available if the Divide field is 0001.
- Conversion between double-precision and single-precision is only available if the double-precision field is nonzero.

SIMDReg, bits [3:0]

Advanced SIMD registers. Indicates whether the Advanced SIMD and floating-point implementation provides support for the Advanced SIMD and floating-point register bank. Defined values are:

- 0000 The implementation has no Advanced SIMD and floating-point support.
- 0001 The implementation includes floating-point support with 16 x 64-bit registers.
- 0010 The implementation includes Advanced SIMD and floating-point support with 32 x 64-bit registers.

All other values are reserved.

In ARMv8-A the permitted values are 0000 and 0010.

Accessing the MVFR0

This register can be read using VMRS with the following syntax:

VMRS <Rt>, <spec_reg>

This syntax is encoded with the following settings in the instruction encoding:

<spec_reg>	reg
MVFR0	0111

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	RO	n/a	RO
x	0	1	-	RO	RO	RO
x	1	1	-	n/a	RO	RO

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When $\text{HCR_EL2.E2H} == 0$:
 - If $\text{CPACR.cp10} == 0$, read accesses to this register from PL1 are UNDEFINED.
- When EL2 is implemented and is using AArch64 and $(\text{SCR_EL3.NS} == 1) \ \&\& \ (\text{HCR_EL2.E2H} == 0)$:
 - If $\text{CPTR_EL2.TFP} == 1$, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If $\text{HCR_EL2.TID3} == 1$, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(\text{SCR_EL3.NS} == 1) \ \&\& \ (\text{HCR_EL2.E2H} == 1) \ \&\& \ (\text{HCR_EL2.TGE} == 0)$:
 - If $\text{CPTR_EL2.FPEN} == 0$, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If $\text{CPTR_EL2.FPEN} == 1$, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If $\text{HCR_EL2.TID3} == 1$, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and $\text{SCR_EL3.NS} == 1$:
 - If $\text{HCPTR.TCP10} == 1$, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
 - If $\text{HCPTR.TCP10} == 0$, Non-secure read accesses to this register from EL2 are UNDEFINED.
 - If $\text{HCR.TID3} == 1$, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
- When EL3 is implemented and is using AArch32 and $\text{SCR_EL3.NS} == 1$:
 - If $\text{NSACR.cp10} == 0$, Non-secure read accesses to this register from EL1 and EL2 are UNDEFINED.
- When EL3 is implemented and is using AArch64:
 - If $\text{CPTR_EL3.TFP} == 1$, read accesses to this register from EL1 and EL2 are trapped to EL3.

G6.2.108 MVFR1, Media and VFP Feature Register 1

The MVFR1 characteristics are:

Purpose

Describes the features provided by the AArch32 Advanced SIMD and Floating-point implementation.

Must be interpreted with [MVFR0](#) and [MVFR2](#).

For general information about the interpretation of the ID registers see [Principles of the ID scheme for fields in ID registers on page G4-4701](#).

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register MVFR1 is architecturally mapped to AArch64 System register [MVFR1_EL1](#).

Implemented only if the implementation includes Advanced SIMD and floating-point instructions.

Attributes

MVFR1 is a 32-bit register.

Field descriptions

The MVFR1 bit assignments are:

SIMDFMAC, bits [31:28]

Advanced SIMD Fused Multiply-Accumulate. Indicates whether the Advanced SIMD implementation provides fused multiply accumulate instructions. Defined values are:

0000 Not implemented.

0001 Implemented.

All other values are reserved.

In ARMv8-A the permitted values are 0000 and 0001.

The Advanced SIMD and floating-point implementations must provide the same level of support for these instructions.

FPHP, bits [27:24]

Floating Point Half Precision. Indicates the level of half-precision floating-point support. Defined values are:

0000 Not supported.

0001 Floating-point half-precision conversion instructions are supported for conversion between single-precision and half-precision.

0010 Floating-point half-precision conversion instructions are supported for conversion between single-precision and half-precision and between double-precision and half-precision.

0011 As for 0010, and also includes support for half-precision floating-point arithmetic.

All other values are reserved.

The permitted values are:

- 0000 in an implementation without floating-point support.
- 0010 in an implementation with floating-point support, that does not include the [ARMv8.2-FP16](#) extension.
- 0011 in an implementation with floating-point support, that includes the [ARMv8.2-FP16](#) extension.

SIMDHP, bits [23:20]

Advanced SIMD Half Precision. Indicates the level of half-precision floating-point support. Defined values are:

- | | |
|------|---|
| 0000 | Not supported. |
| 0001 | SIMD half-precision conversion instructions are supported for conversion between single-precision and half-precision. |
| 0010 | As for 0010, and also includes support for half-precision floating-point arithmetic. |

All other values are reserved.

The permitted values are:

- 0000 in an implementation without SIMD floating-point support.
- 0001 in an implementation with SIMD floating-point support, that does not include the [ARMv8.2-FP16](#) extension.
- 0010 in an implementation with SIMD floating-point support, that includes the [ARMv8.2-FP16](#) extension.

SIMDSP, bits [19:16]

Advanced SIMD Single Precision. Indicates whether the Advanced SIMD and floating-point implementation provides single-precision floating-point instructions. Defined values are:

- | | |
|------|---|
| 0000 | Not implemented. |
| 0001 | Implemented. This value is permitted only if the SIMDInt field is 0001. |

All other values are reserved.

In ARMv8-A the permitted values are 0000 and 0001.

SIMDInt, bits [15:12]

Advanced SIMD Integer. Indicates whether the Advanced SIMD and floating-point implementation provides integer instructions. Defined values are:

- | | |
|------|------------------|
| 0000 | Not implemented. |
| 0001 | Implemented. |

All other values are reserved.

In ARMv8-A the permitted values are 0000 and 0001.

SIMDLS, bits [11:8]

Advanced SIMD Load/Store. Indicates whether the Advanced SIMD and floating-point implementation provides load/store instructions. Defined values are:

- | | |
|------|------------------|
| 0000 | Not implemented. |
| 0001 | Implemented. |

All other values are reserved.

In ARMv8-A the permitted values are 0000 and 0001.

FPDNaN, bits [7:4]

Default NaN mode. Indicates whether the floating-point implementation provides support only for the Default NaN mode. Defined values are:

- | | |
|------|--|
| 0000 | Not implemented, or hardware supports only the Default NaN mode. |
|------|--|

0001 Hardware supports propagation of NaN values.
All other values are reserved.
In ARMv8-A the permitted values are 0000 and 0001.

FPFtZ, bits [3:0]

Flush to Zero mode. Indicates whether the floating-point implementation provides support only for the Flush-to-Zero mode of operation. Defined values are:

0000 Not implemented, or hardware supports only the Flush-to-Zero mode of operation.
0001 Hardware supports full denormalized number arithmetic.
All other values are reserved.
In ARMv8-A the permitted values are 0000 and 0001.

Accessing the MVFR1

This register can be read using VMRS with the following syntax:

VMRS <Rt>, <spec_reg>

This syntax is encoded with the following settings in the instruction encoding:

<spec_reg>	reg
MVFR1	0110

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	RO	n/a	RO
x	0	1	-	RO	RO	RO
x	1	1	-	n/a	RO	RO

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When $HCR_EL2.E2H == 0$:
 - If $CPACR.cp10 == 00$, read accesses to this register from PL1 are UNDEFINED.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \&\& (HCR_EL2.E2H == 0)$:
 - If $CPTR_EL2.TFP == 1$, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If $HCR_EL2.TID3 == 1$, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \&\& (HCR_EL2.E2H == 1) \&\& (HCR_EL2.TGE == 0)$:
 - If $CPTR_EL2.FPEN == 00$, Non-secure read accesses to this register from EL1 are trapped to EL2.

- If `CPTR_EL2.FPEN==10`, Non-secure read accesses to this register from EL1 are trapped to EL2.
- If `HCR_EL2.TID3==1`, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and `SCR_EL3.NS == 1`:
 - If `HCPTR.TCP10==1`, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
 - If `HCPTR.TCP10==1`, Non-secure read accesses to this register from EL2 are UNDEFINED.
 - If `HCR.TID3==1`, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
- When EL3 is implemented and is using AArch32 and `SCR_EL3.NS == 1`:
 - If `NSACR.cp10==0`, Non-secure read accesses to this register from EL1 and EL2 are UNDEFINED.
- When EL3 is implemented and is using AArch64:
 - If `CPTR_EL3.TFP==1`, read accesses to this register from EL1 and EL2 are trapped to EL3.

G6.2.109 MVFR2, Media and VFP Feature Register 2

The MVFR2 characteristics are:

Purpose

Describes the features provided by the AArch32 Advanced SIMD and Floating-point implementation.

Must be interpreted with [MVFR0](#) and [MVFR1](#).

For general information about the interpretation of the ID registers see [Principles of the ID scheme for fields in ID registers on page G4-4701](#).

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register MVFR2 is architecturally mapped to AArch64 System register [MVFR2_EL1](#).

Implemented only if the implementation includes Advanced SIMD and floating-point instructions.

Attributes

MVFR2 is a 32-bit register.

Field descriptions

The MVFR2 bit assignments are:

Bits [31:8]

Reserved, RES0.

FPMisc, bits [7:4]

Indicates whether the floating-point implementation provides support for miscellaneous VFP features.

0000 Not implemented, or no support for miscellaneous features.

0001 Support for Floating-point selection.

0010 As 0001, and Floating-point Conversion to Integer with Directed Rounding modes.

0011 As 0010, and Floating-point Round to Integer Floating-point.

0100 As 0011, and Floating-point MaxNum and MinNum.

All other values are reserved.

In ARMv8-A the permitted values are 0000 and 0100.

SIMDMisc, bits [3:0]

Indicates whether the Advanced SIMD implementation provides support for miscellaneous Advanced SIMD features.

0000 Not implemented, or no support for miscellaneous features.

0001 Floating-point Conversion to Integer with Directed Rounding modes.

0010 As 0001, and Floating-point Round to Integer Floating-point.

0011 As 0010, and Floating-point MaxNum and MinNum.

All other values are reserved.

In ARMv8-A the permitted values are 0000 and 0011.

Accessing the MVFR2

This register can be read using VMRS with the following syntax:

VMRS <Rt>, <spec_reg>

This syntax is encoded with the following settings in the instruction encoding:

<spec_reg>	reg
MVFR2	0101

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	RO	n/a	RO
x	0	1	-	RO	RO	RO
x	1	1	-	n/a	RO	RO

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When $HCR_EL2.E2H == 0$:
 - If $CPACR.cp10 == 00$, read accesses to this register from PL1 are UNDEFINED.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \&\& (HCR_EL2.E2H == 0)$:
 - If $CPTR_EL2.TFP == 1$, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If $HCR_EL2.TID3 == 1$, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \&\& (HCR_EL2.E2H == 1) \&\& (HCR_EL2.TGE == 0)$:
 - If $CPTR_EL2.FPEN == 00$, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If $CPTR_EL2.FPEN == 10$, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If $HCR_EL2.TID3 == 1$, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $HCPTR.TCP10 == 1$, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
 - If $HCPTR.TCP10 == 1$, Non-secure read accesses to this register from EL2 are UNDEFINED.
 - If $HCR.TID3 == 1$, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
- When EL3 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $NSACR.cp10 == 0$, Non-secure read accesses to this register from EL1 and EL2 are UNDEFINED.

- When EL3 is implemented and is using AArch64:
 - If `CPTR_EL3.TFP==1`, read accesses to this register from EL1 and EL2 are trapped to EL3.

G6.2.110 NMRR, Normal Memory Remap Register

The NMRR characteristics are:

Purpose

Provides additional mapping controls for memory regions that are mapped as Normal memory by their entry in the [PRRR](#).

Used in conjunction with the [PRRR](#).

Configurations

AArch32 System register NMRR is architecturally mapped to AArch64 System register [MAIR_EL1](#)[63:32].

[MAIR1](#) and NMRR are the same register, with a different view depending on the value of [TTBCR.EAE](#):

- When it is set to 0, the register is as described in NMRR.
- When it is set to 1, the register is as described in [MAIR1](#).

When EL3 is using AArch32, write access to NMRR(S) is disabled when the CP15SSDISABLE signal is asserted HIGH.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

NMRR is a 32-bit register.

Field descriptions

The NMRR bit assignments are:

When [TTBCR.EAE](#)==0:

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OR7	OR6	OR5	OR4	OR3	OR2	OR1	OR0	IR7	IR6	IR5	IR4	IR3	IR2	IR1	IR0																

OR<n>, bits [2n+17:2n+16], for n = 0 to 7

Outer Cacheable property mapping for memory attributes n, if the region is mapped as Normal memory by the [PRRR.TR<n>](#) entry. n is the value of the [TEX\[0\]](#), C, and B bits concatenated. The possible values of this field are:

- 00 Region is Non-cacheable.
- 01 Region is Write-Back, Write-Allocate.
- 10 Region is Write-Through, no Write-Allocate.
- 11 Region is Write-Back, no Write-Allocate.

The meaning of the field with n = 6 is IMPLEMENTATION DEFINED and might differ from the meaning given here. This is because the meaning of the attribute combination {[TEX\[0\]](#) = 1, C = 1, B = 0} is IMPLEMENTATION DEFINED.

IR<n>, bits [2n+1:2n], for n = 0 to 7

Inner Cacheable property mapping for memory attributes n, if the region is mapped as Normal memory by the [PRRR.TR<n>](#) entry. n is the value of the [TEX\[0\]](#), C, and B bits concatenated. The possible values of this field are:

- 00 Region is Non-cacheable.
- 01 Region is Write-Back, Write-Allocate.

10 Region is Write-Through, no Write-Allocate.

11 Region is Write-Back, no Write-Allocate.

The meaning of the field with $n = 6$ is IMPLEMENTATION DEFINED and might differ from the meaning given here. This is because the meaning of the attribute combination $\{TEX[0] = 1, C = 1, B = 0\}$ is IMPLEMENTATION DEFINED.

Accessing the NMRR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c10, c2, 1	000	001	1010	1111	0010

Accessibility

The register is accessible in software as follows:

Configuration	Control			Accessibility				Instance
	E2H	TGE	NS	EL0	EL1	EL2	EL3	
EL3 is using AArch32.	x	x	0	-	n/a	n/a	RW	NMRR_s
EL3 is not implemented.	x	x	0	-	RW	n/a	n/a	NMRR
EL3 is not implemented.	x	0	1	-	RW	RW	n/a	NMRR
EL3 is not implemented.	x	1	1	-	n/a	RW	n/a	NMRR
EL3 is using AArch64.	x	x	0	-	RW	n/a	n/a	NMRR
EL3 is using AArch64.	x	0	1	-	RW	RW	n/a	NMRR
EL3 is using AArch64.	x	1	1	-	n/a	RW	n/a	NMRR
EL3 is using AArch32.	x	0	1	-	RW	RW	RW	NMRR_ns
EL3 is using AArch32.	x	1	1	-	n/a	RW	RW	NMRR_ns

When EL3 is using AArch32, write access to NMRR_s is UNDEFINED when the CP15SSDISABLE signal is asserted HIGH.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 0)$:
 - If $HCR_EL2.TVM == 1$, Non-secure write accesses to this register from EL1 are trapped to EL2.

- If `HCR_EL2.TRVM==1`, Non-secure read accesses to this register from EL1 are trapped to EL2.
- If `HSTR_EL2.T10==1`, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and `(SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0)`:
 - If `HCR_EL2.TVM==1`, Non-secure write accesses to this register from EL1 are trapped to EL2.
 - If `HCR_EL2.TRVM==1`, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If `HSTR_EL2.T10==1`, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and `SCR_EL3.NS == 1`:
 - If `HCR.TVM==1`, Non-secure write accesses to this register from EL1 are trapped to Hyp mode.
 - If `HCR.TRVM==1`, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
 - If `HSTR.T10==1`, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

G6.2.111 NSACR, Non-Secure Access Control Register

The NSACR characteristics are:

Purpose

When EL3 is implemented and can use AArch32, defines the Non-secure access permissions to Trace, Advanced SIMD and floating-point functionality. Also includes IMPLEMENTATION DEFINED bits that can define Non-secure access permissions for IMPLEMENTATION DEFINED functionality.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

———— Note ————

In AArch64 state, the NSACR controls are replaced by controls in [CPTR_EL3](#).

Some or all RW fields of this register have defined reset values. These apply whenever the register is accessible. This means they apply when the PE resets into EL3 using AArch32.

Attributes

NSACR is a 32-bit register.

Field descriptions

The NSACR bit assignments are:

If EL3 is implemented and is using AArch64 then:

- Any read of the NSACR from Non-secure EL2 or Non-secure EL1 returns a value of `0x0000C00`.
- Any read or write to NSACR from Secure EL1 is trapped as an exception to EL3.

If EL3 is not implemented, then any read of the NSACR from EL2 or EL1 returns a value of `0x0000C00`.

Bits [31:21]

Reserved, RES0.

NSTRCDIS, bit [20]

Disables Non-secure System register accesses to all implemented trace registers.

0 This control has no effect on:

- System register access to implemented trace registers.
- The behavior of [CPACR.TRCDIS](#) and [HCPTR.TTA](#).

1 Non-secure System register accesses to all implemented trace registers are disabled, meaning:

- [CPACR.TRCDIS](#) behaves as RAO/WI in Non-secure state, regardless of its actual value.
- [HCPTR.TTA](#) behaves as RAO/WI, regardless of its actual value.

The implementation of this field must correspond to the implementation of the [CPACR.TRCDIS](#) field:

- If [CPACR.TRCDIS](#) is RAZ/WI, this field is RAZ/WI.
- If [CPACR.TRCDIS](#) is RW, this field is RW.

———— **Note** ————

- The ETMv4 architecture does not permit EL0 to access the trace registers. If the implementation includes an ETMv4 implementation, EL0 accesses to the trace registers are UNDEFINED.
- The architecture does not provide Non-secure access controls on trace register accesses through the optional memory-mapped external debug interface.

System register accesses to the trace registers can have side-effects. When a System register access is trapped, any side-effects that are normally associated with the access do not occur before the exception is taken.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to 0.

Bit [19]

Reserved, RES0.

IMPLEMENTATION DEFINED, bits [18:16]

IMPLEMENTATION DEFINED.

NSASEDIS, bit [15]

Disables Non-secure access to the Advanced SIMD functionality.

0 This control has no effect on:

- Non-secure access to Advanced SIMD functionality.
- The behavior of [CPACR.ASEDIS](#) and [HCPTR.TASE](#).

1 Non-secure access to the Advanced SIMD functionality is disabled, meaning:

- [CPACR.ASEDIS](#) behaves as RAO/WI in Non-secure state, regardless of its actual value.
- [HCPTR.TASE](#) behaves as RAO/WI, regardless of its actual value.

The implementation of this field must correspond to the implementation of the [CPACR.ASEDIS](#) field:

- If [CPACR.ASEDIS](#) is RES0, this field is RES0. If the implementation does not include Advanced SIMD and floating-point functionality, this field is RES0.
- If [CPACR.ASEDIS](#) is RAZ/WI, this field is RAZ/WI.
- If [CPACR.ASEDIS](#) is RW, this field is RW.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to 0.

Bits [14:12]

Reserved, RES0.

cp11, bit [11]

The value of this field is ignored. If this field is programmed with a different value to the cp10 field then this field is UNKNOWN on a direct read of the NSACR.

If the implementation does not include Advanced SIMD and floating-point functionality, this field is RES0.

If this field is implemented as an RW field, it resets to a value that is architecturally UNKNOWN.

cp10, bit [10]

Enable Non-secure access to the Advanced SIMD and floating-point features. Possible values of the fields are:

0 Advanced SIMD and floating-point features can be accessed only from Secure state. Any attempt to access this functionality from Non-secure state is UNDEFINED.

When the PE is in Non-secure state:

- The **CPACR**.{cp11, cp10} fields ignore writes and read as 0b00, access denied.
- The **HCPTR**.{TCP11, TCP10} fields behave as RAO/WI, regardless of their actual values.

1 Advanced SIMD and floating-point features can be accessed from both Security states.

If Non-secure access to the Advanced SIMD and floating-point functionality is enabled, the **CPACR** must be checked to determine the level of access that is permitted.

The Advanced SIMD and floating-point features controlled by these fields are:

- Execution of any floating-point or Advanced SIMD instruction.
- Any access to the Advanced SIMD and floating-point registers D0-D31 and their views as S0-S31 and Q0-Q15.
- Any access to the **FPSCR**, **FPSID**, **MVFR0**, **MVFR1**, **MVFR2**, or **FPEXC** System registers.

If the implementation does not include Advanced SIMD and floating-point functionality, this field is RES0.

If this field is implemented as an RW field, it resets to a value that is architecturally UNKNOWN.

Bits [9:0]

Reserved, RES0.

Accessing the NSACR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c1, c1, 2	000	010	0001	1111	0001

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	RW
x	0	1	-	RO	RO	RW
x	1	1	-	n/a	RO	RW

If EL3 is implemented and is using AArch64, any read from or write to NSACR from Secure EL1 is trapped as an exception to EL3.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 0)$:
 - If $HSTR_EL2.T1 == 1$, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 1) \ \&\& \ (HCR_EL2.TGE == 0)$:
 - If $HSTR_EL2.T1 == 1$, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $HSTR.T1 == 1$, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.

G6.2.112 PAR, Physical Address Register

The PAR characteristics are:

Purpose

Returns the output address (OA) from an address translation instruction that executed successfully, or fault information if the instruction did not execute successfully.

Configurations

AArch32 System register PAR is architecturally mapped to AArch64 System register [PAR_EL1](#).

The PAR returns a 32-bit value:

- When the PE is not in Hyp mode and is using the Short-descriptor translation table format.
- When the PE is in Hyp mode and executes an [ATS12NSOPR](#), [ATS12NSOPW](#), [ATS12NSOUR](#), or [ATS12NSOUW](#) instruction when the value of [HCR.VM](#) is 0 and the value of [TTBCR.EAE](#) is 0.

In these cases, PAR[63:32] is RES0.

Otherwise, the PAR returns a 64-bit value. This means it returns a 64-bit value in the following cases:

- When using the Long-descriptor translation table format.
- If the stage 1 address translation is disabled and [TTBCR.EAE](#) is set to 1.
- In an implementation that includes EL2, for the result of an [ATS1Cxx](#) instruction performed from Hyp mode.

For PL1&0 stage 1 translations, [TTBCR.EAE](#) selects the translation table format.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PAR is a 64-bit register that can also be accessed as a 32-bit value. If it is accessed as a 32-bit register, accesses read and write bits[31:0] and do not modify bits[63:32].

The Configurations section specifies the cases where each PAR format is used.

Field descriptions

The PAR bit assignments are:

For all register layouts:

F, bit [0]

Indicates whether the instruction performed a successful address translation.

- | | |
|---|---|
| 0 | Address translation completed successfully. |
| 1 | Address translation aborted. |

When the instruction returned a 32-bit value to the PAR, PAR.F==0:

This section describes the register value returned by the successful execution of an Address translation instruction. Software might subsequently write a different value to the register, and that write does not affect the operation of the PE.

On a successful conversion, the PAR can return a value that indicates the resulting attributes, rather than the values that appear in the translation table descriptors. More precisely:

- Memory attribute fields are permitted to report the resulting attributes, as determined by any permitted implementation choices and any applicable configuration bits, instead of reporting the values that appear in the translation table descriptors. This applies to the NOS, SH, Inner, and Outer fields.
- See the NS bit description for constraints on the value it returns.

PA, bits [31:12]

Output address. The output address (OA) corresponding to the supplied input address. This field returns address bits[31:12].

LPAE, bit [11]

When updating the PAR with the result of the translation operation, this bit is set as follows:

- 0 Short-descriptor translation table format used. This means the PAR returned a 32-bit value.

NOS, bit [10]

Not Outer Shareable. When the returned value of PAR.SH is 1, indicates the Shareability attribute for the physical memory region:

- 0 Memory region is Outer Shareable.
- 1 Memory region is Inner Shareable.

When the returned value of PAR.SH is 0 the value returned to this field is UNKNOWN.

The value returned in this field can be the resulting attribute, as determined by any permitted implementation choices and any applicable configuration bits, instead of the value that appears in the translation table descriptor.

NS, bit [9]

Non-secure. The NS attribute for a translation table entry from a Secure translation regime.

For a result from a Secure translation regime, this bit reflects the Security state of the physical address space of the translation. This means it reflects the effect of the NSTable bits of earlier levels of the translation table walk if those NSTable bits have an effect on the translation.

For a result from a Non-secure translation regime, this bit is UNKNOWN.

IMP DEF, bit [8]

IMPLEMENTATION DEFINED.

SH, bit [7]

Shareability. Indicates whether the physical memory region is Non-shareable:

- | | |
|---|--|
| 0 | Memory is Non-shareable. |
| 1 | Memory is shareable, and PAR.NOS indicates whether the region is Outer Shareable or Inner Shareable. |

The value returned in this field can be the resulting attribute, as determined by any permitted implementation choices and any applicable configuration bits, instead of the value that appears in the translation table descriptor.

Inner[2:0], bits [6:4]

Inner cacheability attribute for the region. Permitted values are:

- | | |
|-----|--------------------------------|
| 000 | Non-cacheable. |
| 001 | Device-nGnRnE. |
| 011 | Device-nGnRE. |
| 101 | Write-Back, Write-Allocate. |
| 110 | Write-Through. |
| 111 | Write-Back, no Write-Allocate. |

The values 010 and 100 are reserved.

The value returned in this field can be the resulting attribute, as determined by any permitted implementation choices and any applicable configuration bits, instead of the value that appears in the translation table descriptor.

Outer[1:0], bits [3:2]

Outer cacheability attribute for the region. Permitted values are:

- | | |
|----|-----------------------------------|
| 00 | Non-cacheable. |
| 01 | Write-Back, Write-Allocate. |
| 10 | Write-Through, no Write-Allocate. |
| 11 | Write-Back, no Write-Allocate. |

The value returned in this field can be the resulting attribute, as determined by any permitted implementation choices and any applicable configuration bits, instead of the value that appears in the translation table descriptor.

SS, bit [1]

Supersection. Used to indicate if the result is a Supersection:

- | | |
|---|--|
| 0 | Result is not a Supersection. PAR[31:12] contains OA[31:12]. |
| 1 | Result is a Supersection, and: <ul style="list-style-type: none">• PAR[31:24] contains OA[31:24].• PAR[23:16] contains OA[39:32].• PAR[15:12] contains 0b0000. |

If an implementation supports less than 40 bits of physical address, the bits in the PAR field that correspond to physical address bits that are not implemented are UNKNOWN.

F, bit [0]

Indicates whether the instruction performed a successful address translation.

- | | |
|---|---|
| 0 | Address translation completed successfully. |
|---|---|

When the instruction returned a 32-bit value to the PAR, PAR.F==1:

This section describes the register value returned by a fault on the execution of an Address translation instruction. Software might subsequently write a different value to the register, and that write does not affect the operation of the PE.

IMP DEF, bits [31:16]

IMPLEMENTATION DEFINED.

Bits [15:12]

Reserved, RES0.

LPAE, bit [11]

When updating the PAR with the result of the translation operation, this bit is set as follows:

0 Short-descriptor translation table format used. This means the PAR returned a 32-bit value.

Bits [10:7]

Reserved, RES0.

FS, bits [6:1]

Fault status bits. Bits [12,10,3:0] from the [DFSR](#), indicating the source of the abort.

F, bit [0]

Indicates whether the instruction performed a successful address translation.

1 Address translation aborted.

When the instruction returned a 64-bit value to the PAR, PAR.F==0:

This section describes the register value returned by the successful execution of an Address translation instruction. Software might subsequently write a different value to the register, and that write does not affect the operation of the PE.

On a successful conversion, the PAR can return a value that indicates the resulting attributes, rather than the values that appear in the translation table descriptors. More precisely:

- Memory attribute fields are permitted to report the resulting attributes, as determined by any permitted implementation choices and any applicable configuration bits, instead of reporting the values that appear in the translation table descriptors. This applies to the ATTR and SH fields.

- See the NS bit description for constraints on the value it returns.

ATTR, bits [63:56]

Memory attributes for the returned output address. This field uses the same encoding as the Attr<n> fields in MAIRO and MAIR1.

The value returned in this field can be the resulting attribute, as determined by any permitted implementation choices and any applicable configuration bits, instead of the value that appears in the translation table descriptor.

Bits [55:40]

Reserved, RES0.

PA, bits [39:12]

Output address. The output address (OA) corresponding to the supplied input address. This field returns address bits[39:12].

LPAE, bit [11]

When updating the PAR with the result of the translation operation, this bit is set as follows:

- 1 Long-descriptor translation table format used. This means the PAR returned a 64-bit value.

IMP DEF, bit [10]

IMPLEMENTATION DEFINED.

NS, bit [9]

Non-secure. The NS attribute for a translation table entry from a Secure translation regime.

For a result from a Secure translation regime, this bit reflects the Security state of the physical address space of the translation. This means it reflects the effect of the NSTable bits of earlier levels of the translation table walk if those NSTable bits have an effect on the translation.

For a result from a Non-secure translation regime, this bit is UNKNOWN.

SH, bits [8:7]

Shareability attribute, for the returned output address. Permitted values are:

- 00 Non-shareable.
- 10 Outer Shareable.
- 11 Inner Shareable.

The value 01 is reserved.

———— **Note** —————

This field returns the value 10 for:

- Any type of Device memory.
- Normal memory with both Inner Non-cacheable and Outer Non-cacheable attributes.

The value returned in this field can be the resulting attribute, as determined by any permitted implementation choices and any applicable configuration bits, instead of the value that appears in the translation table descriptor.

Bits [6:1]

Reserved, RES0.

F, bit [0]

Indicates whether the instruction performed a successful address translation.

- 0 Address translation completed successfully.

When the instruction returned a 64-bit value to the PAR, PAR.F==1:

This section describes the register value returned by a fault on the execution of an Address translation instruction. Software might subsequently write a different value to the register, and that write does not affect the operation of the PE.

IMP DEF, bits [63:56]

IMPLEMENTATION DEFINED.

IMP DEF, bits [55:52]

IMPLEMENTATION DEFINED.

IMP DEF, bits [51:48]

IMPLEMENTATION DEFINED.

Bits [47:12]

Reserved, RES0.

LPAAE, bit [11]

When updating the PAR with the result of the translation operation, this bit is set as follows:

- 1 Long-descriptor translation table format used. This means the PAR returned a 64-bit value.

Bit [10]

Reserved, RES0.

FSTAGE, bit [9]

Indicates the translation stage at which the translation aborted:

- 0 Translation aborted because of a fault in the stage 1 translation.
- 1 Translation aborted because of a fault in the stage 2 translation.

S2WLK, bit [8]

If this bit is set to 1, it indicates the translation aborted because of a stage 2 fault during a stage 1 translation table walk.

Bit [7]

Reserved, RES0.

FST, bits [6:1]

Fault status field. Values are as in the [DFSR.STATUS](#) and [IFSR.STATUS](#) fields when using the Long-descriptor translation table format.

F, bit [0]

Indicates whether the instruction performed a successful address translation.

- 1 Address translation aborted.

Accessing the PAR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c7, c4, 0	000	000	0111	1111	0100

This register can be read using MRRC with the following syntax:

MRRC <syntax>

This register can be written using MCRR with the following syntax:

MCRR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	coproc	CRm
p15, 0, <Rt>, <Rt2>, c7	0000	1111	0111

Accessibility

The register is accessible in software as follows:

Configuration	Control			Accessibility				Instance
	E2H	TGE	NS	EL0	EL1	EL2	EL3	
EL3 is not implemented.	x	x	0	-	RW	n/a	n/a	PAR
EL3 is not implemented.	x	0	1	-	RW	RW	n/a	PAR
EL3 is not implemented.	x	1	1	-	n/a	RW	n/a	PAR
EL3 is using AArch64.	x	x	0	-	RW	n/a	n/a	PAR
EL3 is using AArch64.	x	0	1	-	RW	RW	n/a	PAR
EL3 is using AArch64.	x	1	1	-	n/a	RW	n/a	PAR
EL3 is using AArch32.	x	0	1	-	RW	RW	RW	PAR_ns
EL3 is using AArch32.	x	1	1	-	n/a	RW	RW	PAR_ns
EL3 is using AArch32.	x	x	0	-	n/a	n/a	RW	PAR_s

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 0)$:
 - If $HSTR_EL2.T7 == 1$, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 1) \ \&\& \ (HCR_EL2.TGE == 0)$:
 - If $HSTR_EL2.T7 == 1$, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $HSTR.T7 == 1$, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

G6.2.113 PRRR, Primary Region Remap Register

The PRRR characteristics are:

Purpose

Controls the top level mapping of the TEX[0], C, and B memory region attributes.

Configurations

AArch32 System register PRRR is architecturally mapped to AArch64 System register [MAIR_EL1](#)[31:0].

[MAIRO](#) and PRRR are the same register, with a different view depending on the value of [TTBCR.EAE](#):

- When it is set to 0, the register is as described in PRRR.
- When it is set to 1, the register is as described in [MAIRO](#).

When EL3 is using AArch32, write access to PRRR(S) is disabled when the CP15SDISABLE signal is asserted HIGH.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PRRR is a 32-bit register.

Field descriptions

The PRRR bit assignments are:

When *TTBCR.EAE*==0:

NOS<n>, bit [n+24], for n = 0 to 7

Not Outer Shareable. NOS<n> is the Outer Shareable property for memory attributes n, if the region is mapped as Normal memory that is not Inner Non-cacheable, Outer Non-cacheable, and the appropriate PRRR. {NS0, NS1} field identifies the region as shareable. n is the value of the concatenation of the {TEX[0], C, B} bits from the translation table descriptor. The possible values of each NOS<n> field other than NOS6 are:

- 0 Memory region is Outer Shareable.
- 1 Memory region is Inner Shareable.

The value of this bit is ignored if the region is:

- Device memory
- Normal memory that is at least one of:
 - Inner Non-cacheable, Outer Non-cacheable.
 - Identified by the appropriate PRRR.{NS0, NS1} field as Non-shareable.

The meaning of the NOS6 field is IMPLEMENTATION DEFINED.

Bits [23:20]

Reserved, RES0.

NS1, bit [19]

Mapping of S = 1 attribute for Normal memory regions. This field is used in determining the Shareability of a memory region that is mapped to Normal memory and both:

- Is not Inner Non-cacheable, Outer Non-cacheable.
- Has the S bit in the translation table descriptor set to 1.

The possible values of this bit are:

- | | |
|---|--|
| 0 | Region is Non-shareable. |
| 1 | Region is shareable. The value of the appropriate PRRR.NOS<n> field determines whether the region is Inner Shareable or Outer Shareable. |

NS0, bit [18]

Mapping of S = 0 attribute for Normal memory regions. This field is used in determining the Shareability of a memory region that is mapped to Normal memory and both:

- Is not Inner Non-cacheable, Outer Non-cacheable.
- Has the S bit in the translation table descriptor set to 0.

The possible values of this bit are:

- | | |
|---|--|
| 0 | Region is Non-shareable. |
| 1 | Region is shareable. The value of the appropriate PRRR.NOS<n> field determines whether the region is Inner Shareable or Outer Shareable. |

DS1, bit [17]

Mapping of S = 1 attribute for Device memory. In ARMv8, all types of Device memory are Outer Shareable, and therefore this bit is RES1.

DS0, bit [16]

Mapping of S = 0 attribute for Device memory. In ARMv8, all types of Device memory are Outer Shareable, and therefore this bit is RES1.

TR<n>, bits [2n+1:2n], for n = 0 to 7

TR<n> is the primary TEX mapping for memory attributes n, and defines the mapped memory type for a region with attributes n. n is the value of the concatenation of the {TEX[0], C, B} bits from the translation table descriptor. The possible values for each field other than TR6 are:

- | | |
|----|----------------------|
| 00 | Device-nGnRnE memory |
| 01 | Device-nGnRE memory |
| 10 | Normal memory |

The value 11 is reserved. The effect of programming a field to 11 is CONSTRAINED UNPREDICTABLE, see [Reserved values in System and memory-mapped registers and translation table entries on page K1-6117](#).

The meaning of the TR6 field is IMPLEMENTATION DEFINED.

Accessing the PRRR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c10, c2, 0	000	000	1010	1111	0010

Accessibility

The register is accessible in software as follows:

Configuration	Control			Accessibility				Instance
	E2H	TGE	NS	EL0	EL1	EL2	EL3	
EL3 is not implemented.	x	x	0	-	RW	n/a	n/a	PRRR
EL3 is not implemented.	x	0	1	-	RW	RW	n/a	PRRR
EL3 is not implemented.	x	1	1	-	n/a	RW	n/a	PRRR
EL3 is using AArch64.	x	x	0	-	RW	n/a	n/a	PRRR
EL3 is using AArch64.	x	0	1	-	RW	RW	n/a	PRRR
EL3 is using AArch64.	x	1	1	-	n/a	RW	n/a	PRRR
EL3 is using AArch32.	x	x	0	-	n/a	n/a	RW	PRRR_s
EL3 is using AArch32.	x	0	1	-	RW	RW	RW	PRRR_ns
EL3 is using AArch32.	x	1	1	-	n/a	RW	RW	PRRR_ns

When EL3 is using AArch32, write access to PRRR_s is UNDEFINED when the CP15SDISABLE signal is asserted HIGH.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If HCR_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
 - If HCR_EL2.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If HSTR_EL2.T10==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If HCR_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.

- If `HCR_EL2.TRVM==1`, Non-secure read accesses to this register from EL1 are trapped to EL2.
- If `HSTR_EL2.T10==1`, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and `SCR_EL3.NS == 1`:
 - If `HCR.TVM==1`, Non-secure write accesses to this register from EL1 are trapped to Hyp mode.
 - If `HCR.TRVM==1`, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
 - If `HSTR.T10==1`, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

G6.2.114 REVIDR, Revision ID Register

The REVIDR characteristics are:

Purpose

Provides implementation-specific minor revision information.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register REVIDR is architecturally mapped to AArch64 System register [REVIDR_EL1](#).

If REVIDR has the same value as [MIDR](#), then its contents have no significance.

Attributes

REVIDR is a 32-bit register.

Field descriptions

The REVIDR bit assignments are:

IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

Accessing the REVIDR

This register can be read using MRC with the following syntax:

MRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c0, c0, 6	000	110	0000	1111	0000

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	RO	n/a	RO
x	0	1	-	RO	RO	RO
x	1	1	-	n/a	RO	RO

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \&\& (HCR_EL2.E2H == 0)$:
 - If $HCR_EL2.TID1 == 1$, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If $HSTR_EL2.T0 == 1$, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \&\& (HCR_EL2.E2H == 1) \&\& (HCR_EL2.TGE == 0)$:
 - If $HCR_EL2.TID1 == 1$, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If $HSTR_EL2.T0 == 1$, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $HCR.TID1 == 1$, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
 - If $HSTR.T0 == 1$, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.

G6.2.115 RMR, Reset Management Register

The RMR characteristics are:

Purpose

If EL1 or EL3 is the highest implemented Exception level and this register is implemented:

- A write to the register at the highest implemented Exception level can request a Warm reset.
- If the highest implemented Exception level can use AArch32 and AArch64, this register specifies the Execution state that the PE boots into on a Warm reset.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register RMR is architecturally mapped to AArch64 System register [RMR_EL1](#) when EL1 is highest implemented Exception level.

AArch32 System register RMR is architecturally mapped to AArch64 System register [RMR_EL3](#) when EL3 is implemented.

Only implemented if EL1 or EL3 is the highest implemented Exception level. In this case:

- If the highest implemented Exception level can use AArch32 and AArch64 then this register must be implemented.
- If the highest implemented Exception level cannot use AArch64 then it is IMPLEMENTATION DEFINED whether the register is implemented.

See the field descriptions for the reset values. These apply whenever the register is implemented.

Attributes

RMR is a 32-bit register.

Field descriptions

The RMR bit assignments are:

Bits [31:2]

Reserved, RES0.

RR, bit [1]

Reset Request. Setting this bit to 1 requests a Warm reset.

This field resets to 0 on a Warm or Cold reset.

AA64, bit [0]

When the highest implemented Exception level can use AArch64, determines which Execution state the PE boots into after a Warm reset:

- 0 AArch32.
- 1 AArch64.

On coming out of the Warm reset, execution starts at the IMPLEMENTATION DEFINED reset vector address of the specified Execution state.

If the highest implemented Exception level cannot use AArch64 this bit is RAZ/WI.

When implemented as a RW field, this field resets to 0 on a Cold reset.

Accessing the RMR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c12, c0, 2	000	010	1100	1111	0000

Accessibility

The register is accessible in software as follows:

Configuration	Control			Accessibility			
	E2H	TGE	NS	EL0	EL1	EL2	EL3
EL1 is the highest implemented Exception level.	x	x	x	-	RW	n/a	n/a
EL2 is the highest implemented Exception level.	x	0	1	-	-	-	n/a
EL2 is the highest implemented Exception level.	x	1	1	-	n/a	-	n/a
EL3 is the highest implemented Exception level.	x	x	0	-	-	n/a	RW
EL3 is the highest implemented Exception level.	x	0	1	-	-	-	RW
EL3 is the highest implemented Exception level.	x	1	1	-	n/a	-	RW

The encoding for this register is UNDEFINED:

- If the RMR is not implemented.
- At all Exception levels other than the highest implemented Exception level.

When EL3 is implemented, ARM deprecates accessing this register from any PE mode other than Monitor mode.

G6.2.116 RVBAR, Reset Vector Base Address Register

The RVBAR characteristics are:

Purpose

If EL3 is not implemented, contains the IMPLEMENTATION DEFINED address that execution starts from after reset when executing in AArch32 state.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

This register is only implemented if the highest Exception level implemented is capable of using AArch32, and is not EL3.

Attributes

RVBAR is a 32-bit register.

Field descriptions

The RVBAR bit assignments are:

Bits [31:1]

Reset Address[31:1]. Bits [31:1] of the IMPLEMENTATION DEFINED address that execution starts from after reset when executing in 32-bit state.

Bit [0]

Reserved, RES1.

Accessing the RVBAR

This register can be read using MRC with the following syntax:

MRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c12, c0, 1	000	001	1100	1111	0000

Accessibility

The register is accessible in software as follows:

Configuration	Control			Accessibility			
	E2H	TGE	NS	EL0	EL1	EL2	EL3
EL1 is the highest implemented Exception level.	x	x	x	-	RO	n/a	n/a
EL2 is the highest implemented Exception level.	x	0	1	-	-	RO	n/a
EL2 is the highest implemented Exception level.	x	1	1	-	n/a	RO	n/a
EL3 is the highest implemented Exception level.	x	x	0	-	-	n/a	-
EL3 is the highest implemented Exception level.	x	0	1	-	-	-	-
EL3 is the highest implemented Exception level.	x	1	1	-	n/a	-	-

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If HSTR_EL2.T12==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If HSTR_EL2.T12==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HSTR.T12==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

G6.2.117 SCR, Secure Configuration Register

The SCR characteristics are:

Purpose

When EL3 is implemented and can use AArch32, defines the configuration of the current Security state. It specifies:

- The Security state, either Secure or Non-secure.
- What mode the PE branches to if an IRQ, FIQ, or External Abort occurs.
- Whether the CPSR.F or CPSR.A bits can be modified when SCR.NS==1.

Configurations

This register is only accessible in Secure state.

AArch32 System register SCR can be mapped to AArch64 System register [SCR_EL3](#), but this is not architecturally mandated.

Some or all RW fields of this register have defined reset values. These apply whenever the register is accessible. This means they apply when the PE resets into EL3 using AArch32.

Attributes

SCR is a 32-bit register.

Field descriptions

The SCR bit assignments are:

Bits [31:16]

Reserved, RES0.

TERR, bit [15]

Trap Error record accesses. If the RAS Extension is implemented, the possible values of this bit are:

- 0 Do not trap accesses to record registers from EL1 and EL2 to EL3.
- 1 Accesses to the ER* registers from EL1 and EL2 generate a Trap exception to EL3.

This bit resets to 0 on Warm reset.

When the RAS Extension is not implemented, this field is RES0.

Bit [14]

Reserved, RES0.

TWE, bit [13]

Traps WFE instructions to Monitor mode.

- 0 This control does not cause any instructions to be trapped.
- 1 Any attempt to execute a WFE instruction in any mode other than Monitor mode is trapped to Monitor mode, if the instruction would otherwise have caused the PE to enter a low-power state and the attempted execution does not generate an exception that is taken to EL1 or EL2 by [SCTLR.nTWE](#) or [HCR.TWE](#).
Any exception that is taken to EL1 or to EL2 has priority over this trap.

The attempted execution of a conditional WFE instruction is only trapped if the instruction passes its condition code check.

———— Note ————

Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE of WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

When this register has an architecturally-defined reset value, this field resets to 0.

TWI, bit [12]

Traps WFI instructions to Monitor mode.

- 0 This control does not cause any instructions to be trapped.
- 1 Any attempt to execute a WFI instruction in any mode other than Monitor mode is trapped to Monitor mode, if the instruction would otherwise have caused the PE to enter a low-power state and the attempted execution does not generate an exception that is taken to EL1 or EL2 by [SCTLR.nTWI](#) or [HCR.TWI](#).
Any exception that is taken to EL1 or to EL2 has priority over this trap.

The attempted execution of a conditional WFI instruction is only trapped if the instruction passes its condition code check.

———— Note ————

Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE of WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

When this register has an architecturally-defined reset value, this field resets to 0.

Bits [11:10]

Reserved, RES0.

SIF, bit [9]

Secure instruction fetch. When the PE is in Secure state, this bit disables instruction fetch from Non-secure memory. The possible values for this bit are:

- 0 Secure state instruction fetches from Non-secure memory are permitted.
- 1 Secure state instruction fetches from Non-secure memory are not permitted.

This bit is permitted to be cached in a TLB.

When this register has an architecturally-defined reset value, this field resets to 0.

HCE, bit [8]

Hypervisor Call instruction enable. Enables EL2 and Non-secure EL1 execution of HVC instructions.

- 0 HVC instructions are:
- UNDEFINED at Non-secure EL1. The Undefined Instruction exception is taken from PL1 to PL1.
 - UNPREDICTABLE at EL2. Behavior is one of the following:
 - The instruction is UNDEFINED.
 - The instruction executes as a NOP.
- 1 HVC instructions are enabled at EL2 and Non-secure EL1.

———— **Note** ————

HVC instructions are always UNDEFINED at EL0 and in Secure state.

If EL2 is not implemented, this bit is RES0 and HVC is UNDEFINED.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to 0.

SCD, bit [7]

Secure Monitor Call disable. Disables SMC instructions.

- 0 SMC instructions are enabled.
- 1 In Non-secure state, SMC instructions are UNDEFINED. The Undefined Instruction exception is taken from the current Exception level to the current Exception level. In Secure state, behavior is one of the following:
- The instruction is UNDEFINED.
 - The instruction executes as a NOP.

———— **Note** ————

SMC instructions are always UNDEFINED at PL0.

When this register has an architecturally-defined reset value, this field resets to 0.

nET, bit [6]

Not Early Termination. This bit disables early termination. The possible values of this bit are:

- 0 Early termination permitted. Execution time of data operations can depend on the data values.
- 1 Disable early termination. The number of cycles required for data operations is forced to be independent of the data values.

This IMPLEMENTATION DEFINED mechanism can disable data dependent timing optimizations from multiplies and data operations. It can provide system support against information leakage that might be exploited by timing correlation types of attack.

On implementations that do not support early termination or do not support disabling early termination, this bit is RES0.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to 0.

AW, bit [5]

When the value of SCR.EA is 1 and the value of HCR.AMO is 0, this bit controls whether CPSR.A masks an external abort taken from Non-secure state, and the possible values of this bit are:

- 0 External aborts taken from Non-secure state are not masked by CPSR.A, and are taken to EL3.
External aborts taken from Secure state are masked by CPSR.A.

1 External aborts taken from either Security state are masked by **CPSR.A**. When **CPSR.A** is 0, the abort is taken to EL3.

When **SCR.EA** is 0 or **HCR.AMO** is 1, this bit has no effect.

When this register has an architecturally-defined reset value, this field resets to 0.

FW, bit [4]

When the value of **SCR.FIQ** is 1 and the value of **HCR.FMO** is 0, this bit controls whether **CPSR.F** masks an FIQ interrupt taken from Non-secure state, and the possible values of this bit are:

0 An FIQ taken from Non-secure state is not masked by **CPSR.F**, and is taken to EL3.
An FIQ taken from Secure state is masked by **CPSR.F**.

1 An FIQ taken from either Security state is masked by **CPSR.F**. When **CPSR.F** is 0, the FIQ is taken to EL3.

When **SCR.FIQ** is 0 or **HCR.FMO** is 1, this bit has no effect.

When this register has an architecturally-defined reset value, this field resets to 0.

EA, bit [3]

External Abort handler. This bit controls which mode takes external aborts. The possible values of this bit are:

0 External aborts taken to Abort mode.

1 External aborts taken to Monitor mode.

When this register has an architecturally-defined reset value, this field resets to 0.

FIQ, bit [2]

FIQ handler. This bit controls which mode takes FIQ exceptions. The possible values of this bit are:

0 FIQs taken to FIQ mode.

1 FIQs taken to Monitor mode.

When this register has an architecturally-defined reset value, this field resets to 0.

IRQ, bit [1]

IRQ handler. This bit controls which mode takes IRQ exceptions. The possible values of this bit are:

0 IRQs taken to IRQ mode.

1 IRQs taken to Monitor mode.

When this register has an architecturally-defined reset value, this field resets to 0.

NS, bit [0]

Non-secure bit. Except when the PE is in Monitor mode, this bit determines the Security state of the PE:

0 PE is in Secure state.

1 PE is in Non-secure state.

If the **HCR.TGE** bit is set, an attempt to change from a Secure PL1 mode to a Non-secure EL1 mode by changing the **SCR.NS** bit from 0 to 1 results in the **SCR.NS** bit remaining as 0.

When this register has an architecturally-defined reset value, this field resets to 0.

Accessing the SCR

This register can be read using MRC with the following syntax:

```
MRC <syntax>
```

This register can be written using MCR with the following syntax:

```
MCR <syntax>
```

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c1, c1, 0	000	000	0001	1111	0001

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	RW
x	0	1	-	-	-	RW
x	1	1	-	n/a	-	RW

If EL3 is implemented and is using AArch64, any read or write to SCR from Secure EL1 using AArch32 is trapped as an exception to EL3.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If HSTR_EL2.T1==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If HSTR_EL2.T1==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HSTR.T1==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

G6.2.118 SCTLR, System Control Register

The SCTLR characteristics are:

Purpose

Provides the top level control of the system, including its memory system.

Configurations

AArch32 System register SCTLR is architecturally mapped to AArch64 System register [SCTLR_EL1](#).

When EL3 is using AArch32, write access to SCTLR(S) is disabled when the CP15SDISABLE signal is asserted HIGH.

Some bits in the register are read-only. These bits relate to non-configurable features of an implementation, and are provided for compatibility with previous versions of the architecture.

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into an Exception level that is using AArch32. If the PE resets into EL3 using AArch32 they apply only to the Secure instance of the register. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

Attributes

SCTLR is a 32-bit register.

Field descriptions

The SCTLR bit assignments are:

Bit [31]

Reserved, RES0.

TE, bit [30]

T32 Exception Enable. This bit controls whether exceptions to an Exception Level that is executing at PL1 are taken to A32 or T32 state:

- 0 Exceptions, including reset, taken to A32 state.
- 1 Exceptions, including reset, taken to T32 state.

When this register has an architecturally-defined reset value, this field resets to an IMPLEMENTATION DEFINED choice between:

- 0.
- A value determined by an input configuration signal.

AFE, bit [29]

Access Flag Enable. When using the Short-descriptor translation table format for the PL1&0 translation regime, this bit enables use of the AP[0] bit in the translation descriptors as the Access flag, and restricts access permissions in the translation descriptors to the simplified model. The possible values of this bit are:

- | | |
|---|---|
| 0 | In the translation table descriptors, AP[0] is an access permissions bit. The full range of access permissions is supported. No Access flag is implemented. |
| 1 | In the translation table descriptors, AP[0] is the Access flag. Only the simplified model for access permissions is supported. |

When using the Long-descriptor translation table format, the VMSA behaves as if this bit is set to 1, regardless of the value of this bit.

The AFE bit is permitted to be cached in a TLB.

When this register has an architecturally-defined reset value, this field resets to 0.

TRE, bit [28]

TEX remap enable. This bit enables remapping of the TEX[2:1] bits in the PL1&0 translation regime for use as two translation table bits that can be managed by the operating system. Enabling this remapping also changes the scheme used to describe the memory region attributes in the VMSA. The possible values of this bit are:

- | | |
|---|--|
| 0 | TEX remap disabled. TEX[2:0] are used, with the C and B bits, to describe the memory region attributes. |
| 1 | TEX remap enabled. TEX[2:1] are reassigned for use as bits managed by the operating system. The TEX[0], C, and B bits are used to describe the memory region attributes, with the MMU remap registers. |

When the value of [TTBCR.EAE](#) is 1, this bit is RES1.

The TRE bit is permitted to be cached in a TLB.

When this register has an architecturally-defined reset value, this field resets to 0.

Bits [27:26]

Reserved, RES0.

EE, bit [25]

The value of the PSTATE.E bit on branch to an exception vector or coming out of reset, and the endianness of stage 1 translation table walks in the PL1&0 translation regime.

The possible values of this bit are:

- | | |
|---|---|
| 0 | Little-endian. PSTATE.E is cleared to 0 on taking an exception or coming out of reset. Stage 1 translation table walks in the PL1&0 translation regime are little-endian. |
| 1 | Big-endian. PSTATE.E is cleared to 0 on taking an exception or coming out of reset. Stage 1 translation table walks in the PL1&0 translation regime are big-endian. |

If an implementation does not provide Big-endian support for data accesses at Exception Levels higher than EL0, this bit is RES0.

If an implementation does not provide Little-endian support for data accesses at Exception Levels higher than EL0, this bit is RES1.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to an IMPLEMENTATION DEFINED choice between:

- 0.
- A value determined by an input configuration signal.

Bit [24]

Reserved, RES0.

SPAN, bit [23]

In ARMv8.2 and ARMv8.1

Set Privileged Access Never, on taking an exception to EL1 from either Secure or Non-secure state, or to EL3 from Secure state when EL3 is using AArch32.

0 **CPSR.PAN** is set to 1 in the following situations:

- In Non-secure state, on taking an exception to EL1.
- In Secure state, when EL3 is using AArch64, on taking an exception to EL1.
- In Secure state, when EL3 is using AArch32, on taking an exception to EL3.

1 The value of **CPSR.PAN** is left unchanged on taking an exception.

In ARMv8.0.

Reserved, RES1.

Bit [22]

Reserved, RES1.

Bit [21]

Reserved, RES0.

UWXN, bit [20]

Unprivileged write permission implies PL1 XN (Execute-never). This bit can force all memory regions that are writable at PL0 to be treated as XN for accesses from software executing at PL1. The possible values of this bit are:

0 This control has no effect on memory access permissions.

1 Any region that is writable at PL0 forced to XN for accesses from software executing at PL1.

The UWXN bit is permitted to be cached in a TLB.

When this register has an architecturally-defined reset value, this field resets to 0.

WXN, bit [19]

Write permission implies XN (Execute-never). For the PL1&0 translation regime, this bit can force all memory regions that are writable to be treated as XN. The possible values of this bit are:

0 This control has no effect on memory access permissions.

1 Any region that is writable in the PL1&0 translation regime is forced to XN for accesses from software executing at PL1 or PL0.

The WXN bit is permitted to be cached in a TLB.

When this register has an architecturally-defined reset value, this field resets to 0.

nTWE, bit [18]

Traps EL0 execution of WFE instructions to Undefined mode.

0 Any attempt to execute a WFE instruction at EL0 is trapped to Undefined mode, if the instruction would otherwise have caused the PE to enter a low-power state.

1 This control does not cause any instructions to be trapped.

The attempted execution of a conditional WFE instruction is only trapped if the instruction passes its condition code check.

———— **Note** ————

Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE of WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

When this register has an architecturally-defined reset value, this field resets to 1.

Bit [17]

Reserved, RES0.

nTWI, bit [16]

Traps EL0 execution of WFI instructions to Undefined mode.

- 0 Any attempt to execute a WFI instruction at EL0 is trapped to Undefined mode, if the instruction would otherwise have caused the PE to enter a low-power state.
- 1 This control does not cause any instructions to be trapped.

The attempted execution of a conditional WFI instruction is only trapped if the instruction passes its condition code check.

———— **Note** ————

Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE of WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

When this register has an architecturally-defined reset value, this field resets to 1.

Bits [15:14]

Reserved, RES0.

V, bit [13]

Vectors bit. This bit selects the base address of the exception vectors for exceptions taken to a PE mode other than Monitor mode or Hyp mode:

- 0 Normal exception vectors. Base address is held in [VBAR](#).
- 1 High exception vectors (Hivecs), base address 0xFFFF0000. This base address cannot be remapped.

When this register has an architecturally-defined reset value, this field resets to an IMPLEMENTATION DEFINED choice between:

- 0.
- A value determined by an input configuration signal.

I, bit [12]

Instruction access Cacheability control, for accesses at EL1 and EL0:

- 0 All instruction access to Normal memory from PL1 and PL0 are Non-cacheable for all levels of instruction and unified cache.
If the value of SCTL.R.M is 0, instruction accesses from stage 1 of the PL1&0 translation regime are to Normal, Outer Shareable, Inner Non-cacheable, Outer Non-cacheable memory.
- 1 All instruction access to Normal memory from PL1 and PL0 can be cached at all levels of instruction and unified cache.
If the value of SCTL.R.M is 0, instruction accesses from stage 1 of the PL1&0 translation regime are to Normal, Outer Shareable, Inner Write-Through, Outer Write-Through memory.

Instruction accesses to Normal memory from Non-secure EL1 and Non-secure EL0 are Cacheable regardless of the value of the SCTLR.I bit if either:

- EL2 is using AArch32 and the value of HCR.DC is 1.
- EL2 is using AArch64 and the value of HCR_EL2.DC is 1.

When this register has an architecturally-defined reset value, this field resets to 0.

Bit [11]

Reserved, RES1.

Bits [10:9]

Reserved, RES0.

SED, bit [8]

SETEND instruction disable. Disables SETEND instructions at PL0 and PL1.

- 0 SETEND instruction execution is enabled at PL0 and PL1.
- 1 SETEND instructions are UNDEFINED at PL0 and PL1.

If the implementation does not support mixed-endian operation at any Exception level, this bit is RES1.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to 0.

ITD, bit [7]

IT Disable. Disables some uses of IT instructions at PL1 and PL0.

- 0 All IT instruction functionality is enabled at PL1 and PL0.
- 1 Any attempt at PL1 or PL0 to execute any of the following is UNDEFINED:
 - All encodings of the IT instruction with hw1[3:0] != 1000.
 - All encodings of the subsequent instruction with the following values for hw1:
 - 11xxxxxxxxxxxx
All 32-bit instructions, and the 16-bit instructions B, UDF, SVC, LDM, and STM.
 - 1011xxxxxxxxxxxx
All instructions in *Miscellaneous 16-bit instructions on page F3-2883*.
 - 1010xxxxxxxxxxxx
ADD Rd, PC, #imm
 - 01001xxxxxxxxxxx
LDR Rd, [PC, #imm]
 - 0100x1xxx1111xxx
ADD Rdn, PC; CMP Rn, PC; MOV Rd, PC; BX PC; BLX PC.
 - 010001xx1xxxx111
ADD PC, Rm; CMP PC, Rm; MOV PC, Rm. This pattern also covers UNPREDICTABLE cases with BLX Rn.

These instructions are always UNDEFINED, regardless of whether they would pass or fail the condition code check that applies to them as a result of being in an IT block.

It is IMPLEMENTATION DEFINED whether the IT instruction is treated as:

- A 16-bit instruction, that can only be followed by another 16-bit instruction.
- The first half of a 32-bit instruction.

This means that, for the situations that are UNDEFINED, either the second 16-bit instruction or the 32-bit instruction is UNDEFINED.

An implementation might vary dynamically as to whether IT is treated as a 16-bit instruction or the first half of a 32-bit instruction.

If an instruction in an active IT block that would be disabled by this field sets this field to 1 then behavior is CONSTRAINED UNPREDICTABLE. For more information see [Changes to an ITD control by an instruction in an IT block on page E1-2738](#).

ITD is optional, but if it is implemented in the SCTLR then it must also be implemented in the [SCTLR_EL1](#). If it is not implemented then this bit is RAZ/WI.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to 0.

UNK, bit [6]

Writes to this bit are IGNORED. Reads of this bit return an UNKNOWN value.

CP15BEN, bit [5]

System instruction memory barrier enable. Enables accesses to the DMB, DSB, and ISB System instructions in the (coproc==1111) encoding space from PL1 and PL0:

- | | |
|---|---|
| 0 | PL0 and PL1 execution of the CP15DMB , CP15DSB , and CP15ISB instructions is UNDEFINED. |
| 1 | PL0 and PL1 execution of the CP15DMB , CP15DSB , and CP15ISB instructions is enabled. |

CP15BEN is optional, but if it is implemented in the SCTLR then it must also be implemented in the [SCTLR_EL1](#). If it is not implemented then this bit is RAO/WI.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to 1.

LSMAOE, bit [4]

In ARMv8.2

Load Multiple and Store Multiple Atomicity and Ordering Enable. When the OPTIONAL feature [ARMv8.2-LSMAOC](#) is implemented, defined values are:

- | | |
|---|--|
| 0 | For all memory accesses at EL1 or EL0, A32 and T32 Load Multiple and Store Multiple can have an interrupt taken during the sequence memory accesses, and the memory accesses are not required to be ordered. |
| 1 | The ordering and interrupt behavior of A32 and T32 Load Multiple and Store Multiple at EL1 or EL0 is as defined for ARMv8.0. |

This bit is permitted to be cached in a TLB.

If this bit is not implemented, it is RES1.

When this register has an architecturally-defined reset value, this field resets to 1.

In ARMv8.1 and ARMv8.0.

Reserved, RES1.

nTLSMD, bit [3]

In ARMv8.2

No Trap Load Multiple and Store Multiple to Device-nGRE/Device-nGnRE/Device-nGnRnE memory. When the OPTIONAL feature [ARMv8.2-LSMAOC](#) is implemented, defined values are:

- | | |
|---|---|
| 0 | All memory accesses by A32 and T32 Load Multiple and Store Multiple at EL1 or EL0 that are marked at stage 1 as Device-nGRE/Device-nGnRE/Device-nGnRnE memory are trapped and generate a stage 1 Alignment fault. |
| 1 | All memory accesses by A32 and T32 Load Multiple and Store Multiple at EL1 or EL0 that are marked at stage 1 as Device-nGRE/Device-nGnRE/Device-nGnRnE memory are not trapped. |

This bit is permitted to be cached in a TLB.

If this bit is not implemented, it is RES1.

When this register has an architecturally-defined reset value, this field resets to 1.

In ARMv8.1 and ARMv8.0.

Reserved, RES1.

C, bit [2]

Cacheability control, for data accesses at EL1 and EL0:

- | | |
|---|--|
| 0 | All data access to Normal memory from PL1 and PL0, and all accesses to the PL1&0 stage 1 translation tables, are Non-cacheable for all levels of data and unified cache. |
| 1 | All data access to Normal memory from PL1 and PL0, and all accesses to the PL1&0 stage 1 translation tables, can be cached at all levels of data and unified cache. |

The PE ignores SCLTR.C for Non-secure state and data accesses to Normal memory from EL1 and EL0 are Cacheable if either:

- EL2 is using AArch32 and the value of HCR.DC is 1.
- EL2 is using AArch64 and the value of HCR_EL2.DC is 1.

When this register has an architecturally-defined reset value, this field resets to 0.

A, bit [1]

Alignment check enable. This is the enable bit for Alignment fault checking at PL1 and PL0:

- | | |
|---|---|
| 0 | Alignment fault checking disabled when executing at PL1 or PL0.
Instructions that load or store one or more registers, other than load/store exclusive and load-acquire/store-release, do not check that the address being accessed is aligned to the size of the data element(s) being accessed. |
| 1 | Alignment fault checking enabled when executing at PL1 or PL0.
All instructions that load or store one or more registers have an alignment check that the address being accessed is aligned to the size of the data element(s) being accessed. If this check fails it causes an Alignment fault, which is taken as a Data Abort exception. |

Load/store exclusive and load-acquire/store-release instructions have an alignment check regardless of the value of the A bit.

When this register has an architecturally-defined reset value, this field resets to 0.

M, bit [0]

MMU enable for EL1 and EL0 stage 1 address translation. Possible values of this bit are:

- | | |
|---|---|
| 0 | EL1 and EL0 stage 1 address translation disabled.
See the SCLTR.I field for the behavior of instruction accesses to Normal memory. |
| 1 | EL1 and EL0 stage 1 address translation enabled. |

In the Non-secure state the PE behaves as if the value of the SCLTR.M field is 0 for all purposes other than returning the value of a direct read of the field if either:

- EL2 is using AArch32 and the value of HCR.{DC, TGE} is not {0, 0}.
- EL2 is using AArch64 and the value of HCR_EL2.{DC, TGE} is not {0, 0}.

When this register has an architecturally-defined reset value, this field resets to 0.

Accessing the SCLTR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c1, c0, 0	000	000	0001	1111	0000

Accessibility

The register is accessible in software as follows:

Configuration	Control			Accessibility				Instance
	E2H	TGE	NS	EL0	EL1	EL2	EL3	
EL3 is not implemented.	x	x	0	-	RW	n/a	n/a	SCTLR
EL3 is not implemented.	x	0	1	-	RW	RW	n/a	SCTLR
EL3 is not implemented.	x	1	1	-	n/a	RW	n/a	SCTLR
EL3 is using AArch64.	x	x	0	-	RW	n/a	n/a	SCTLR
EL3 is using AArch64.	x	0	1	-	RW	RW	n/a	SCTLR
EL3 is using AArch64.	x	1	1	-	n/a	RW	n/a	SCTLR
EL3 is using AArch32.	x	x	0	-	n/a	n/a	RW	SCTLR_s
EL3 is using AArch32.	x	0	1	-	RW	RW	RW	SCTLR_ns
EL3 is using AArch32.	x	1	1	-	n/a	RW	RW	SCTLR_ns

When EL3 is using AArch32, write access to SCTLR_s is UNDEFINED when the CP15SSDISABLE signal is asserted HIGH.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If HCR_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
 - If HCR_EL2.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If HSTR_EL2.T1==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If HCR_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
 - If HCR_EL2.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If HSTR_EL2.T1==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HCR.TVM==1, Non-secure write accesses to this register from EL1 are trapped to Hyp mode.
 - If HCR.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
 - If HSTR.T1==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

G6.2.119 SPSR, Saved Program Status Register

The SPSR characteristics are:

Purpose

Holds the saved process state for the current mode.

Configurations

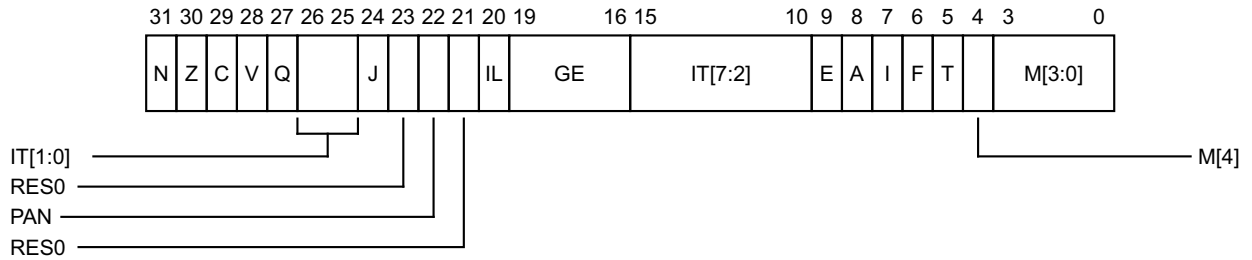

There is one instance of this register that is used in both Secure and Non-secure states.

Attributes

SPSR is a 32-bit register.

Field descriptions

The SPSR bit assignments are:

N, bit [31]

Set to the value of **CPSR.N** on taking an exception to the current mode, and copied to **CPSR.N** on executing an exception return operation in the current mode.

Z, bit [30]

Set to the value of **CPSR.Z** on taking an exception to the current mode, and copied to **CPSR.Z** on executing an exception return operation in the current mode.

C, bit [29]

Set to the value of **CPSR.C** on taking an exception to the current mode, and copied to **CPSR.C** on executing an exception return operation in the current mode.

V, bit [28]

Set to the value of **CPSR.V** on taking an exception to the current mode, and copied to **CPSR.V** on executing an exception return operation in the current mode.

Q, bit [27]

Set to the value of **CPSR.Q** on taking an exception to the current mode, and copied to **CPSR.Q** on executing an exception return operation in the current mode.

IT[1:0], bits [26:25]

IT block state bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

J, bit [24]

RES0.

In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state. ARMv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

Bit [23]

Reserved, RES0.

PAN, bit [22]

In ARMv8.2 and ARMv8.1

When [ARMv8.1-PAN](#) is implemented, set to the value of [CPSR.PAN](#) on taking an exception to the current mode, and copied to [CPSR.PAN](#) on executing an exception return operation in the current mode.

When [ARMv8.1-PAN](#) is not implemented, this bit is RES0.

In ARMv8.0.

Reserved, RES0.

Bit [21]

Reserved, RES0.

IL, bit [20]

Illegal Execution state bit. Shows the value of [PSTATE.IL](#) immediately before the exception was taken.

GE, bits [19:16]

Greater than or Equal flags, for parallel addition and subtraction.

IT[7:2], bits [15:10]

IT block state bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is `0b00000000` when no IT block is active.

E, bit [9]

Endianness state bit. Controls the load and store endianness for data accesses:

0 Little-endian operation

1 Big-endian operation.

Instruction fetches ignore this bit.

When the reset value of the [SCTLR.EE](#) bit is defined by a configuration input signal, that value also applies to the [CPSR.E](#) bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any Exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any Exception level other than EL0.

A, bit [8]

SError interrupt mask bit. The possible values of this bit are:

0 Exception not masked.

1 Exception masked.

I, bit [7]

IRQ mask bit. The possible values of this bit are:

- 0 Exception not masked.
- 1 Exception masked.

F, bit [6]

FIQ mask bit. The possible values of this bit are:

- 0 Exception not masked.
- 1 Exception masked.

T, bit [5]

T32 Instruction set state bit. Determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:

- 0 Taken from A32 state.
- 1 Taken from T32 state.

M[4], bit [4]

Execution state that the exception was taken from. Possible values of this bit are:

- 1 Exception taken from AArch32.

M[3:0], bits [3:0]

AArch32 mode that an exception was taken from. The possible values are:

M[3:0]	Mode
0b0000	User
0b0001	FIQ
0b0010	IRQ
0b0011	Supervisor
0b0110	Monitor (only valid in Secure state, if EL3 is implemented and can use AArch32)
0b0111	Abort
0b1010	Hyp
0b1011	Undefined
0b1111	System

Other values are reserved.

G6.2.120 SPSR_abt, Saved Program Status Register (Abort mode)

The SPSR_abt characteristics are:

Purpose

Holds the saved process state when an exception is taken to Abort mode.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register SPSR_abt is architecturally mapped to AArch64 System register [SPSR_abt](#).

Attributes

SPSR_abt is a 32-bit register.

Field descriptions

The SPSR_abt bit assignments are:

N, bit [31]

Set to the value of [CPSR.N](#) on taking an exception to Abort mode, and copied to [CPSR.N](#) on executing an exception return operation in Abort mode.

Z, bit [30]

Set to the value of [CPSR.Z](#) on taking an exception to Abort mode, and copied to [CPSR.Z](#) on executing an exception return operation in Abort mode.

C, bit [29]

Set to the value of [CPSR.C](#) on taking an exception to Abort mode, and copied to [CPSR.C](#) on executing an exception return operation in Abort mode.

V, bit [28]

Set to the value of [CPSR.V](#) on taking an exception to Abort mode, and copied to [CPSR.V](#) on executing an exception return operation in Abort mode.

Q, bit [27]

Set to the value of [CPSR.Q](#) on taking an exception to Abort mode, and copied to [CPSR.Q](#) on executing an exception return operation in Abort mode.

IT[1:0], bits [26:25]

IT block state bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

J, bit [24]

RES0.

In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state. ARMv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

Bit [23]

Reserved, RES0.

PAN, bit [22]

In ARMv8.2 and ARMv8.1

When [ARMv8.1-PAN](#) is implemented, set to the value of [CPSR.PAN](#) on taking an exception to Abort mode, and copied to [CPSR.PAN](#) on executing an exception return operation in Abort mode.

When [ARMv8.1-PAN](#) is not implemented, this bit is RES0.

In ARMv8.0.

Reserved, RES0.

Bit [21]

Reserved, RES0.

IL, bit [20]

Illegal Execution state bit. Shows the value of [PSTATE.IL](#) immediately before the exception was taken.

GE, bits [19:16]

Greater than or Equal flags, for parallel addition and subtraction.

IT[7:2], bits [15:10]

IT block state bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is `0b00000000` when no IT block is active.

E, bit [9]

Endianness state bit. Controls the load and store endianness for data accesses:

0 Little-endian operation

1 Big-endian operation.

Instruction fetches ignore this bit.

When the reset value of the [SCTLR.EE](#) bit is defined by a configuration input signal, that value also applies to the [CPSR.E](#) bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any Exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any Exception level other than EL0.

A, bit [8]

SError interrupt mask bit. The possible values of this bit are:

0 Exception not masked.

1 Exception masked.

I, bit [7]

IRQ mask bit. The possible values of this bit are:

- 0 Exception not masked.
- 1 Exception masked.

F, bit [6]

FIQ mask bit. The possible values of this bit are:

- 0 Exception not masked.
- 1 Exception masked.

T, bit [5]

T32 Instruction set state bit. Determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:

- 0 Taken from A32 state.
- 1 Taken from T32 state.

M[4], bit [4]

Execution state that the exception was taken from. Possible values of this bit are:

- 1 Exception taken from AArch32.

M[3:0], bits [3:0]

AArch32 mode that an exception was taken from. The possible values are:

M[3:0]	Mode
0b0000	User
0b0001	FIQ
0b0010	IRQ
0b0011	Supervisor
0b0110	Monitor (only valid in Secure state, if EL3 is implemented and can use AArch32)
0b0111	Abort
0b1011	Undefined
0b1111	System

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is **CONSTRAINED UNPREDICTABLE**, as described in *Reserved values in System and memory-mapped registers and translation table entries* on page K1-6117.

Accessing the SPSR_abt

This register can be read using MRS (banked register) with the following syntax:

MRS <Rd>, <banked_reg>

This register can be written using MSR (banked register) with the following syntax:

MSR <banked_reg>, <Rd>

This syntax is encoded with the following settings in the instruction encoding:

<banked_reg>	R	M	M1
SPSR_abt	1	1	0100

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	RW	n/a	RW
x	0	1	-	RW	RW	RW
x	1	1	-	n/a	RW	RW

Using MRS (banked register) and MSR (banked register) instructions, at PL1 this register is only accessible from PE modes other than Abort mode. In Abort mode, it is accessible as the current SPSR.

G6.2.121 SPSR_fiq, Saved Program Status Register (FIQ mode)

The SPSR_fiq characteristics are:

Purpose

Holds the saved process state when an exception is taken to FIQ mode.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register SPSR_fiq is architecturally mapped to AArch64 System register [SPSR_fiq](#).

Attributes

SPSR_fiq is a 32-bit register.

Field descriptions

The SPSR_fiq bit assignments are:

N, bit [31]

Set to the value of [CPSR.N](#) on taking an exception to FIQ mode, and copied to [CPSR.N](#) on executing an exception return operation in FIQ mode.

Z, bit [30]

Set to the value of [CPSR.Z](#) on taking an exception to FIQ mode, and copied to [CPSR.Z](#) on executing an exception return operation in FIQ mode.

C, bit [29]

Set to the value of [CPSR.C](#) on taking an exception to FIQ mode, and copied to [CPSR.C](#) on executing an exception return operation in FIQ mode.

V, bit [28]

Set to the value of [CPSR.V](#) on taking an exception to FIQ mode, and copied to [CPSR.V](#) on executing an exception return operation in FIQ mode.

Q, bit [27]

Set to the value of [CPSR.Q](#) on taking an exception to FIQ mode, and copied to [CPSR.Q](#) on executing an exception return operation in FIQ mode.

IT[1:0], bits [26:25]

IT block state bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

J, bit [24]

RES0.

In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state. ARMv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

Bit [23]

Reserved, RES0.

PAN, bit [22]

In ARMv8.2 and ARMv8.1

When [ARMv8.1-PAN](#) is implemented, set to the value of [CPSR.PAN](#) on taking an exception to FIQ mode, and copied to [CPSR.PAN](#) on executing an exception return operation in FIQ mode.

When [ARMv8.1-PAN](#) is not implemented, this bit is RES0.

In ARMv8.0.

Reserved, RES0.

Bit [21]

Reserved, RES0.

IL, bit [20]

Illegal Execution state bit. Shows the value of [PSTATE.IL](#) immediately before the exception was taken.

GE, bits [19:16]

Greater than or Equal flags, for parallel addition and subtraction.

IT[7:2], bits [15:10]

IT block state bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is `0b00000000` when no IT block is active.

E, bit [9]

Endianness state bit. Controls the load and store endianness for data accesses:

0 Little-endian operation

1 Big-endian operation.

Instruction fetches ignore this bit.

When the reset value of the [SCTLR.EE](#) bit is defined by a configuration input signal, that value also applies to the [CPSR.E](#) bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any Exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any Exception level other than EL0.

A, bit [8]

SError interrupt mask bit. The possible values of this bit are:

0 Exception not masked.

1 Exception masked.

I, bit [7]

IRQ mask bit. The possible values of this bit are:

- 0 Exception not masked.
- 1 Exception masked.

F, bit [6]

FIQ mask bit. The possible values of this bit are:

- 0 Exception not masked.
- 1 Exception masked.

T, bit [5]

T32 Instruction set state bit. Determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:

- 0 Taken from A32 state.
- 1 Taken from T32 state.

M[4], bit [4]

Execution state that the exception was taken from. Possible values of this bit are:

- 1 Exception taken from AArch32.

M[3:0], bits [3:0]

AArch32 mode that an exception was taken from. The possible values are:

M[3:0]	Mode
0b0000	User
0b0001	FIQ
0b0010	IRQ
0b0011	Supervisor
0b0110	Monitor (only valid in Secure state, if EL3 is implemented and can use AArch32)
0b0111	Abort
0b1011	Undefined
0b1111	System

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is **CONSTRAINED UNPREDICTABLE**, as described in *Reserved values in System and memory-mapped registers and translation table entries* on page K1-6117.

Accessing the SPSR_fiq

This register can be read using MRS (banked register) with the following syntax:

MRS <Rd>, <banked_reg>

This register can be written using MSR (banked register) with the following syntax:

MSR <banked_reg>, <Rd>

This syntax is encoded with the following settings in the instruction encoding:

<banked_reg>	R	M	M1
SPSR_fiq	1	0	1110

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	RW	n/a	RW
x	0	1	-	RW	RW	RW
x	1	1	-	n/a	RW	RW

Using MRS (banked register) and MSR (banked register) instructions, at PL1 this register is only accessible from PE modes other than FIQ mode. In FIQ mode, it is accessible as the current SPSR.

G6.2.122 SPSR_hyp, Saved Program Status Register (Hyp mode)

The SPSR_hyp characteristics are:

Purpose

Holds the saved process state when an exception is taken to Hyp mode.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register SPSR_hyp is architecturally mapped to AArch64 System register [SPSR_EL2](#).

Attributes

SPSR_hyp is a 32-bit register.

Field descriptions

The SPSR_hyp bit assignments are:

N, bit [31]

Set to the value of [CPSR.N](#) on taking an exception to Hyp mode, and copied to [CPSR.N](#) on executing an exception return operation in Hyp mode.

Z, bit [30]

Set to the value of [CPSR.Z](#) on taking an exception to Hyp mode, and copied to [CPSR.Z](#) on executing an exception return operation in Hyp mode.

C, bit [29]

Set to the value of [CPSR.C](#) on taking an exception to Hyp mode, and copied to [CPSR.C](#) on executing an exception return operation in Hyp mode.

V, bit [28]

Set to the value of [CPSR.V](#) on taking an exception to Hyp mode, and copied to [CPSR.V](#) on executing an exception return operation in Hyp mode.

Q, bit [27]

Set to the value of [CPSR.Q](#) on taking an exception to Hyp mode, and copied to [CPSR.Q](#) on executing an exception return operation in Hyp mode.

IT[1:0], bits [26:25]

IT block state bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

J, bit [24]

RES0.

In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state. ARMv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

Bit [23]

Reserved, RES0.

PAN, bit [22]

In ARMv8.2 and ARMv8.1

When [ARMv8.1-PAN](#) is implemented, set to the value of [CPSR.PAN](#) on taking an exception to Hyp mode, and copied to [CPSR.PAN](#) on executing an exception return operation in Hyp mode.

When [ARMv8.1-PAN](#) is not implemented, this bit is RES0.

In ARMv8.0.

Reserved, RES0.

Bit [21]

Reserved, RES0.

IL, bit [20]

Illegal Execution state bit. Shows the value of [PSTATE.IL](#) immediately before the exception was taken.

GE, bits [19:16]

Greater than or Equal flags, for parallel addition and subtraction.

IT[7:2], bits [15:10]

IT block state bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is `0b00000000` when no IT block is active.

E, bit [9]

Endianness state bit. Controls the load and store endianness for data accesses:

0 Little-endian operation

1 Big-endian operation.

Instruction fetches ignore this bit.

When the reset value of the [SCTLR.EE](#) bit is defined by a configuration input signal, that value also applies to the [CPSR.E](#) bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any Exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any Exception level other than EL0.

A, bit [8]

SError interrupt mask bit. The possible values of this bit are:

0 Exception not masked.

1 Exception masked.

I, bit [7]

IRQ mask bit. The possible values of this bit are:

- 0 Exception not masked.
- 1 Exception masked.

F, bit [6]

FIQ mask bit. The possible values of this bit are:

- 0 Exception not masked.
- 1 Exception masked.

T, bit [5]

T32 Instruction set state bit. Determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:

- 0 Taken from A32 state.
- 1 Taken from T32 state.

M[4], bit [4]

Execution state that the exception was taken from. Possible values of this bit are:

- 1 Exception taken from AArch32.

M[3:0], bits [3:0]

AArch32 mode that an exception was taken from. The possible values are:

M[3:0]	Mode
0b0000	User
0b0001	FIQ
0b0010	IRQ
0b0011	Supervisor
0b0111	Abort
0b1010	Hyp
0b1011	Undefined
0b1111	System

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is **CONSTRAINED UNPREDICTABLE**, as described in *Reserved values in System and memory-mapped registers and translation table entries* on page K1-6117.

Accessing the SPSR_hyp

This register can be read using MRS (banked register) with the following syntax:

MRS <Rd>, <banked_reg>

This register can be written using MSR (banked register) with the following syntax:

MSR <banked_reg>, <Rd>

This syntax is encoded with the following settings in the instruction encoding:

<banked_reg>	R	M	M1
SPSR_hyp	1	1	1110

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	RW
x	0	1	-	-	-	RW
x	1	1	-	n/a	-	RW

Using MRS (banked register) and MSR (banked register) instructions, this register is only accessible from Monitor mode. In Hyp mode, this register is accessible as the current SPSR.

G6.2.123 SPSR_irq, Saved Program Status Register (IRQ mode)

The SPSR_irq characteristics are:

Purpose

Holds the saved process state when an exception is taken to IRQ mode.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register SPSR_irq is architecturally mapped to AArch64 System register [SPSR_irq](#).

Attributes

SPSR_irq is a 32-bit register.

Field descriptions

The SPSR_irq bit assignments are:

N, bit [31]

Set to the value of [CPSR.N](#) on taking an exception to IRQ mode, and copied to [CPSR.N](#) on executing an exception return operation in IRQ mode.

Z, bit [30]

Set to the value of [CPSR.Z](#) on taking an exception to IRQ mode, and copied to [CPSR.Z](#) on executing an exception return operation in IRQ mode.

C, bit [29]

Set to the value of [CPSR.C](#) on taking an exception to IRQ mode, and copied to [CPSR.C](#) on executing an exception return operation in IRQ mode.

V, bit [28]

Set to the value of [CPSR.V](#) on taking an exception to IRQ mode, and copied to [CPSR.V](#) on executing an exception return operation in IRQ mode.

Q, bit [27]

Set to the value of [CPSR.Q](#) on taking an exception to IRQ mode, and copied to [CPSR.Q](#) on executing an exception return operation in IRQ mode.

IT[1:0], bits [26:25]

IT block state bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

J, bit [24]

RES0.

In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state. ARMv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

Bit [23]

Reserved, RES0.

PAN, bit [22]

In ARMv8.2 and ARMv8.1

When [ARMv8.1-PAN](#) is implemented, set to the value of [CPSR.PAN](#) on taking an exception to IRQ mode, and copied to [CPSR.PAN](#) on executing an exception return operation in IRQ mode.

When [ARMv8.1-PAN](#) is not implemented, this bit is RES0.

In ARMv8.0.

Reserved, RES0.

Bit [21]

Reserved, RES0.

IL, bit [20]

Illegal Execution state bit. Shows the value of [PSTATE.IL](#) immediately before the exception was taken.

GE, bits [19:16]

Greater than or Equal flags, for parallel addition and subtraction.

IT[7:2], bits [15:10]

IT block state bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is `0b00000000` when no IT block is active.

E, bit [9]

Endianness state bit. Controls the load and store endianness for data accesses:

0 Little-endian operation

1 Big-endian operation.

Instruction fetches ignore this bit.

When the reset value of the [SCTLR.EE](#) bit is defined by a configuration input signal, that value also applies to the [CPSR.E](#) bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any Exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any Exception level other than EL0.

A, bit [8]

SError interrupt mask bit. The possible values of this bit are:

0 Exception not masked.

1 Exception masked.

I, bit [7]

IRQ mask bit. The possible values of this bit are:

- 0 Exception not masked.
- 1 Exception masked.

F, bit [6]

FIQ mask bit. The possible values of this bit are:

- 0 Exception not masked.
- 1 Exception masked.

T, bit [5]

T32 Instruction set state bit. Determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:

- 0 Taken from A32 state.
- 1 Taken from T32 state.

M[4], bit [4]

Execution state that the exception was taken from. Possible values of this bit are:

- 1 Exception taken from AArch32.

M[3:0], bits [3:0]

AArch32 mode that an exception was taken from. The possible values are:

M[3:0]	Mode
0b0000	User
0b0001	FIQ
0b0010	IRQ
0b0011	Supervisor
0b0110	Monitor (only valid in Secure state, if EL3 is implemented and can use AArch32)
0b0111	Abort
0b1011	Undefined
0b1111	System

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is **CONSTRAINED UNPREDICTABLE**, as described in [Reserved values in System and memory-mapped registers and translation table entries on page K1-6117](#).

Accessing the SPSR_irq

This register can be read using MRS (banked register) with the following syntax:

MRS <Rd>, <banked_reg>

This register can be written using MSR (banked register) with the following syntax:

MSR <banked_reg>, <Rd>

This syntax is encoded with the following settings in the instruction encoding:

<banked_reg>	R	M	M1
SPSR_irq	1	1	0000

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	RW	n/a	RW
x	0	1	-	RW	RW	RW
x	1	1	-	n/a	RW	RW

Using MRS (banked register) and MSR (banked register) instructions, at PL1 this register is only accessible from PE modes other than IRQ mode. In IRQ mode, it is accessible as the current SPSR.

G6.2.124 SPSR_mon, Saved Program Status Register (Monitor mode)

The SPSR_mon characteristics are:

Purpose

Holds the saved process state when an exception is taken to Monitor mode.

Configurations

This register is only accessible in Secure state.

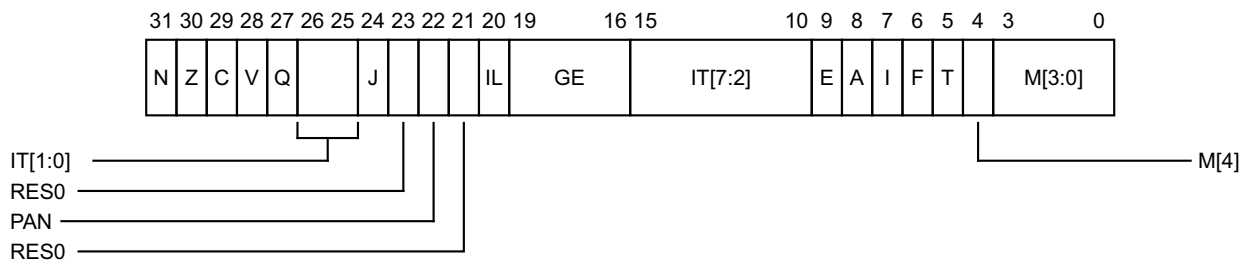

AArch32 System register SPSR_mon can be mapped to AArch64 System register [SPSR_EL3](#), but this is not architecturally mandated.

Attributes

SPSR_mon is a 32-bit register.

Field descriptions

The SPSR_mon bit assignments are:

N, bit [31]

Set to the value of [CPSR.N](#) on taking an exception to Monitor mode, and copied to [CPSR.N](#) on executing an exception return operation in Monitor mode.

Z, bit [30]

Set to the value of [CPSR.Z](#) on taking an exception to Monitor mode, and copied to [CPSR.Z](#) on executing an exception return operation in Monitor mode.

C, bit [29]

Set to the value of [CPSR.C](#) on taking an exception to Monitor mode, and copied to [CPSR.C](#) on executing an exception return operation in Monitor mode.

V, bit [28]

Set to the value of [CPSR.V](#) on taking an exception to Monitor mode, and copied to [CPSR.V](#) on executing an exception return operation in Monitor mode.

Q, bit [27]

Set to the value of [CPSR.Q](#) on taking an exception to Monitor mode, and copied to [CPSR.Q](#) on executing an exception return operation in Monitor mode.

IT[1:0], bits [26:25]

IT block state bits for the T32 IT (If-Then) instruction. See [IT\[7:2\]](#) for explanation of this field.

J, bit [24]

RES0.

In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state. ARMv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

Bit [23]

Reserved, RES0.

PAN, bit [22]

In ARMv8.2 and ARMv8.1

When [ARMv8.1-PAN](#) is implemented, set to the value of [CPSR.PAN](#) on taking an exception to Monitor mode, and copied to [CPSR.PAN](#) on executing an exception return operation in Monitor mode.

When [ARMv8.1-PAN](#) is not implemented, this bit is RES0.

In ARMv8.0.

Reserved, RES0.

Bit [21]

Reserved, RES0.

IL, bit [20]

Illegal Execution state bit. Shows the value of [PSTATE.IL](#) immediately before the exception was taken.

GE, bits [19:16]

Greater than or Equal flags, for parallel addition and subtraction.

IT[7:2], bits [15:10]

IT block state bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is 0b00000000 when no IT block is active.

E, bit [9]

Endianness state bit. Controls the load and store endianness for data accesses:

- | | |
|---|-------------------------|
| 0 | Little-endian operation |
| 1 | Big-endian operation. |

Instruction fetches ignore this bit.

When the reset value of the [SCTLR.EE](#) bit is defined by a configuration input signal, that value also applies to the [CPSR.E](#) bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any Exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any Exception level other than EL0.

A, bit [8]

SError interrupt mask bit. The possible values of this bit are:

- | | |
|---|-----------------------|
| 0 | Exception not masked. |
| 1 | Exception masked. |

I, bit [7]

IRQ mask bit. The possible values of this bit are:

- 0 Exception not masked.
- 1 Exception masked.

F, bit [6]

FIQ mask bit. The possible values of this bit are:

- 0 Exception not masked.
- 1 Exception masked.

T, bit [5]

T32 Instruction set state bit. Determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:

- 0 Taken from A32 state.
- 1 Taken from T32 state.

M[4], bit [4]

Execution state that the exception was taken from. Possible values of this bit are:

- 1 Exception taken from AArch32.

M[3:0], bits [3:0]

AArch32 mode that an exception was taken from. The possible values are:

M[3:0]	Mode
0b0000	User
0b0001	FIQ
0b0010	IRQ
0b0011	Supervisor
0b0110	Monitor (only valid in Secure state, if EL3 is implemented and can use AArch32)
0b0111	Abort
0b1010	Hyp
0b1011	Undefined
0b1111	System

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is CONstrained UNPREDICTABLE, as described in [Reserved values in System and memory-mapped registers and translation table entries on page K1-6117](#).

Accessing the SPSR_mon

This register can be read using MRS (banked register) with the following syntax:

MRS <Rd>, <banked_reg>

This register can be written using MSR (banked register) with the following syntax:

MSR <banked_reg>, <Rd>

This syntax is encoded with the following settings in the instruction encoding:

<banked_reg>	R	M	M1
SPSR_mon	1	1	1100

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	RW
x	0	1	-	-	-	RW
x	1	1	-	n/a	-	RW

Using MRS (banked register) and MSR (banked register) instructions, this register is only accessible from EL3 modes other than Monitor mode. In Monitor mode, it is accessible as the current SPSR.

G6.2.125 SPSR_svc, Saved Program Status Register (Supervisor mode)

The SPSR_svc characteristics are:

Purpose

Holds the saved process state when an exception is taken to Supervisor mode.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

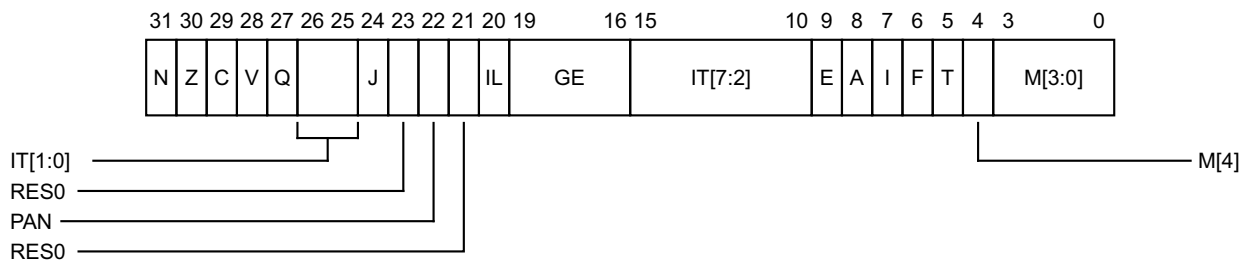

AArch32 System register SPSR_svc is architecturally mapped to AArch64 System register [SPSR_EL1](#).

Attributes

SPSR_svc is a 32-bit register.

Field descriptions

The SPSR_svc bit assignments are:

N, bit [31]

Set to the value of [CPSR.N](#) on taking an exception to Supervisor mode, and copied to [CPSR.N](#) on executing an exception return operation in Supervisor mode.

Z, bit [30]

Set to the value of [CPSR.Z](#) on taking an exception to Supervisor mode, and copied to [CPSR.Z](#) on executing an exception return operation in Supervisor mode.

C, bit [29]

Set to the value of [CPSR.C](#) on taking an exception to Supervisor mode, and copied to [CPSR.C](#) on executing an exception return operation in Supervisor mode.

V, bit [28]

Set to the value of [CPSR.V](#) on taking an exception to Supervisor mode, and copied to [CPSR.V](#) on executing an exception return operation in Supervisor mode.

Q, bit [27]

Set to the value of [CPSR.Q](#) on taking an exception to Supervisor mode, and copied to [CPSR.Q](#) on executing an exception return operation in Supervisor mode.

IT[1:0], bits [26:25]

IT block state bits for the T32 IT (If-Then) instruction. See [IT\[7:2\]](#) for explanation of this field.

J, bit [24]

RES0.

In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state. ARMv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

Bit [23]

Reserved, RES0.

PAN, bit [22]

In ARMv8.2 and ARMv8.1

When [ARMv8.1-PAN](#) is implemented, set to the value of [CPSR.PAN](#) on taking an exception to Supervisor mode, and copied to [CPSR.PAN](#) on executing an exception return operation in Supervisor mode.

When [ARMv8.1-PAN](#) is not implemented, this bit is RES0.

In ARMv8.0.

Reserved, RES0.

Bit [21]

Reserved, RES0.

IL, bit [20]

Illegal Execution state bit. Shows the value of [PSTATE.IL](#) immediately before the exception was taken.

GE, bits [19:16]

Greater than or Equal flags, for parallel addition and subtraction.

IT[7:2], bits [15:10]

IT block state bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is 0b00000000 when no IT block is active.

E, bit [9]

Endianness state bit. Controls the load and store endianness for data accesses:

- | | |
|---|-------------------------|
| 0 | Little-endian operation |
| 1 | Big-endian operation. |

Instruction fetches ignore this bit.

When the reset value of the [SCTLR.EE](#) bit is defined by a configuration input signal, that value also applies to the [CPSR.E](#) bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any Exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any Exception level other than EL0.

A, bit [8]

SError interrupt mask bit. The possible values of this bit are:

- | | |
|---|-----------------------|
| 0 | Exception not masked. |
| 1 | Exception masked. |

I, bit [7]

IRQ mask bit. The possible values of this bit are:

- 0 Exception not masked.
- 1 Exception masked.

F, bit [6]

FIQ mask bit. The possible values of this bit are:

- 0 Exception not masked.
- 1 Exception masked.

T, bit [5]

T32 Instruction set state bit. Determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:

- 0 Taken from A32 state.
- 1 Taken from T32 state.

M[4], bit [4]

Execution state that the exception was taken from. Possible values of this bit are:

- 1 Exception taken from AArch32.

M[3:0], bits [3:0]

AArch32 mode that an exception was taken from. The possible values are:

M[3:0]	Mode
0b0000	User
0b0001	FIQ
0b0010	IRQ
0b0011	Supervisor
0b0110	Monitor (only valid in Secure state, if EL3 is implemented and can use AArch32)
0b0111	Abort
0b1011	Undefined
0b1111	System

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is **CONSTRAINED UNPREDICTABLE**, as described in *Reserved values in System and memory-mapped registers and translation table entries* on page K1-6117.

Accessing the SPSR_svc

This register can be read using MRS (banked register) with the following syntax:

MRS <Rd>, <banked_reg>

This register can be written using MSR (banked register) with the following syntax:

MSR <banked_reg>, <Rd>

This syntax is encoded with the following settings in the instruction encoding:

<banked_reg>	R	M	M1
SPSR_svc	1	1	0010

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	RW	n/a	RW
x	0	1	-	RW	RW	RW
x	1	1	-	n/a	RW	RW

Using MRS (banked register) and MSR (banked register) instructions, at PL1 this register is only accessible from PE modes other than Supervisor mode. In Supervisor mode, it is accessible as the current SPSR.

G6.2.126 SPSR_und, Saved Program Status Register (Undefined mode)

The SPSR_und characteristics are:

Purpose

Holds the saved process state when an exception is taken to Undefined mode.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

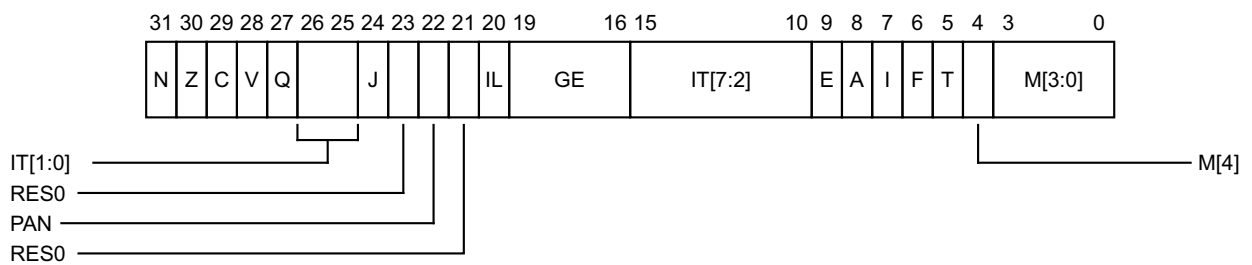

AArch32 System register SPSR_und is architecturally mapped to AArch64 System register [SPSR_und](#).

Attributes

SPSR_und is a 32-bit register.

Field descriptions

The SPSR_und bit assignments are:

N, bit [31]

Set to the value of [CPSR.N](#) on taking an exception to Undefined mode, and copied to [CPSR.N](#) on executing an exception return operation in Undefined mode.

Z, bit [30]

Set to the value of [CPSR.Z](#) on taking an exception to Undefined mode, and copied to [CPSR.Z](#) on executing an exception return operation in Undefined mode.

C, bit [29]

Set to the value of [CPSR.C](#) on taking an exception to Undefined mode, and copied to [CPSR.C](#) on executing an exception return operation in Undefined mode.

V, bit [28]

Set to the value of [CPSR.V](#) on taking an exception to Undefined mode, and copied to [CPSR.V](#) on executing an exception return operation in Undefined mode.

Q, bit [27]

Set to the value of [CPSR.Q](#) on taking an exception to Undefined mode, and copied to [CPSR.Q](#) on executing an exception return operation in Undefined mode.

IT[1:0], bits [26:25]

IT block state bits for the T32 IT (If-Then) instruction. See [IT\[7:2\]](#) for explanation of this field.

J, bit [24]

RES0.

In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state. ARMv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

Bit [23]

Reserved, RES0.

PAN, bit [22]

In ARMv8.2 and ARMv8.1

When [ARMv8.1-PAN](#) is implemented, set to the value of [CPSR.PAN](#) on taking an exception to Undefined mode, and copied to [CPSR.PAN](#) on executing an exception return operation in Undefined mode.

When [ARMv8.1-PAN](#) is not implemented, this bit is RES0.

In ARMv8.0.

Reserved, RES0.

Bit [21]

Reserved, RES0.

IL, bit [20]

Illegal Execution state bit. Shows the value of [PSTATE.IL](#) immediately before the exception was taken.

GE, bits [19:16]

Greater than or Equal flags, for parallel addition and subtraction.

IT[7:2], bits [15:10]

IT block state bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is 0b00000000 when no IT block is active.

E, bit [9]

Endianness state bit. Controls the load and store endianness for data accesses:

- | | |
|---|-------------------------|
| 0 | Little-endian operation |
| 1 | Big-endian operation. |

Instruction fetches ignore this bit.

When the reset value of the [SCTLR.EE](#) bit is defined by a configuration input signal, that value also applies to the [CPSR.E](#) bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any Exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any Exception level other than EL0.

A, bit [8]

SError interrupt mask bit. The possible values of this bit are:

- | | |
|---|-----------------------|
| 0 | Exception not masked. |
| 1 | Exception masked. |

I, bit [7]

IRQ mask bit. The possible values of this bit are:

- 0 Exception not masked.
- 1 Exception masked.

F, bit [6]

FIQ mask bit. The possible values of this bit are:

- 0 Exception not masked.
- 1 Exception masked.

T, bit [5]

T32 Instruction set state bit. Determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:

- 0 Taken from A32 state.
- 1 Taken from T32 state.

M[4], bit [4]

Execution state that the exception was taken from. Possible values of this bit are:

- 1 Exception taken from AArch32.

M[3:0], bits [3:0]

AArch32 mode that an exception was taken from. The possible values are:

M[3:0]	Mode
0b0000	User
0b0001	FIQ
0b0010	IRQ
0b0011	Supervisor
0b0110	Monitor (only valid in Secure state, if EL3 is implemented and can use AArch32)
0b0111	Abort
0b1011	Undefined
0b1111	System

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is **CONSTRAINED UNPREDICTABLE**, as described in *Reserved values in System and memory-mapped registers and translation table entries* on page K1-6117.

Accessing the SPSR_und

This register can be read using MRS (banked register) with the following syntax:

MRS <Rd>, <banked_reg>

This register can be written using MSR (banked register) with the following syntax:

MSR <banked_reg>, <Rd>

This syntax is encoded with the following settings in the instruction encoding:

<banked_reg>	R	M	M1
SPSR_und	1	1	0110

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	RW	n/a	RW
x	0	1	-	RW	RW	RW
x	1	1	-	n/a	RW	RW

Using MRS (banked register) and MSR (banked register) instructions, at PL1 this register is only accessible from PE modes other than Undefined mode. In Undefined mode, it is accessible as the current SPSR.

G6.2.127 TCMTR, TCM Type Register

The TCMTR characteristics are:

Purpose

Provides information about the implementation of the TCM.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

Attributes

TCMTR is a 32-bit register.

Field descriptions

The TCMTR bit assignments are:

IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

Accessing the TCMTR

This register can be read using MRC with the following syntax:

MRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c0, c0, 2	000	010	0000	1111	0000

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	RO	n/a	RO
x	0	1	-	RO	RO	RO
x	1	1	-	n/a	RO	RO

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \&\& (HCR_EL2.E2H == 0)$:
 - If $HCR_EL2.TID1 == 1$, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If $HSTR_EL2.T0 == 1$, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \&\& (HCR_EL2.E2H == 1) \&\& (HCR_EL2.TGE == 0)$:
 - If $HCR_EL2.TID1 == 1$, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If $HSTR_EL2.T0 == 1$, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $HCR.TID1 == 1$, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
 - If $HSTR.T0 == 1$, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.

G6.2.128 TLBIALL, TLB Invalidate All

The TLBIALL characteristics are:

Purpose

Invalidate all cached copies of translation table entries from TLBs that are from any level of the translation table walk. The entries that are invalidated are as follows:

- If executed at Secure EL1 when EL3 is using AArch64, all entries that would be required for the Secure EL1&0 translation regime.
- If executed in Secure state when EL3 is using AArch32, all entries that would be required for the Secure PL1&0 translation regime.
- If executed at Non-secure EL1, all stage 1 translation table entries that would be required for the Non-secure PL1&0 translation regime and, if EL2 is implemented, they must match the current VMID.
- If executed at EL2, the stage 1 or stage 2 translation table entries that would be required for the Non-secure PL1&0 translation regime and matches the current VMID.

The invalidation only applies to the PE that executes this instruction.

Configurations

There are no configuration notes.

Attributes

TLBIALL is a 32-bit System instruction.

Field descriptions

TLBIALL ignores the value in the register specified by the instruction. Software does not have to write a value to the register before issuing this instruction.

Executing the TLBIALL instruction

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c8, c7, 0	000	000	1000	1111	0111

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	WO	n/a	WO
x	0	1	-	WO	WO	WO
x	1	1	-	n/a	WO	WO

When [HCR.FB](#) is 1, at Non-secure EL1 this instruction executes as a [TLBIALLIS](#).

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \&\& (HCR_EL2.E2H == 0)$:
 - If $HCR_EL2.TTLB == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
 - If $HSTR_EL2.T8 == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \&\& (HCR_EL2.E2H == 1) \&\& (HCR_EL2.TGE == 0)$:
 - If $HCR_EL2.TTLB == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
 - If $HSTR_EL2.T8 == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $HCR.TTLB == 1$, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
 - If $HSTR.T8 == 1$, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

G6.2.129 TLBIALLH, TLB Invalidate All, Hyp mode

The TLBIALLH characteristics are:

Purpose

If EL2 is implemented, invalidate all cached copies of translation table entries from TLBs that are from any level of the translation table walk that would be required for the Non-secure EL2 translation regime.

The invalidation only applies to the PE that executes this instruction.

Configurations

There are no configuration notes.

Attributes

TLBIALLH is a 32-bit System instruction.

Field descriptions

TLBIALLH ignores the value in the register specified by the instruction. Software does not have to write a value to the register before issuing this instruction.

Executing the TLBIALLH instruction

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 4, <Rt>, c8, c7, 0	100	000	1000	1111	0111

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	WO
x	0	1	-	-	WO	WO
x	1	1	-	n/a	WO	WO

If EL2 is not implemented, this instruction is UNDEFINED.

If this instruction is executed in a Secure privileged mode other than Monitor mode, then the behavior is CONSTRAINED UNPREDICTABLE, and one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The instruction executes as if it had been executed in Monitor mode.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 0)$:
 - If $HSTR_EL2.T8 == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 1) \ \&\& \ (HCR_EL2.TGE == 0)$:
 - If $HSTR_EL2.T8 == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $HSTR.T8 == 1$, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

G6.2.130 TLBIALLHIS, TLB Invalidate All, Hyp mode, Inner Shareable

The TLBIALLHIS characteristics are:

Purpose

If EL2 is implemented, invalidate all cached copies of translation table entries from TLBs that are from any level of the translation table walk that would be required for the Non-secure EL2 translation regime.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this instructions.

Configurations

There are no configuration notes.

Attributes

TLBIALLHIS is a 32-bit System instruction.

Field descriptions

TLBIALLHIS ignores the value in the register specified by the instruction. Software does not have to write a value to the register before issuing this instruction.

Executing the TLBIALLHIS instruction

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 4, <Rt>, c8, c3, 0	100	000	1000	1111	0011

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	WO
x	0	1	-	-	WO	WO
x	1	1	-	n/a	WO	WO

If EL2 is not implemented, this instruction is UNDEFINED.

If this instruction is executed in a Secure privileged mode other than Monitor mode, then the behavior is CONSTRAINED UNPREDICTABLE, and one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The instruction executes as if it had been executed in Monitor mode.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 0)$:
 - If $HSTR_EL2.T8 == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 1) \ \&\& \ (HCR_EL2.TGE == 0)$:
 - If $HSTR_EL2.T8 == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $HSTR.T8 == 1$, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

G6.2.131 TLBIALLIS, TLB Invalidate All, Inner Shareable

The TLBIALLIS characteristics are:

Purpose

Invalidate all cached copies of translation table entries from TLBs that are from any level of the translation table walk. The entries that are invalidated are as follows:

- If executed at Secure EL1 when EL3 is using AArch64, all entries that would be required for the Secure EL1&0 translation regime.
- If executed in Secure state when EL3 is using AArch32, all entries that would be required for the Secure PL1&0 translation regime.
- If executed at Non-secure EL1, all stage 1 translation table entries that would be required for the Non-secure PL1&0 translation regime and, if EL2 is implemented, they must match the current VMID.
- If executed at EL2, the stage 1 or stage 2 translation table entries that would be required for the Non-secure PL1&0 translation regime and matches the current VMID.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this instructions.

Configurations

There are no configuration notes.

Attributes

TLBIALLIS is a 32-bit System instruction.

Field descriptions

TLBIALLIS ignores the value in the register specified by the instruction. Software does not have to write a value to the register before issuing this instruction.

Executing the TLBIALLIS instruction

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c8, c3, 0	000	000	1000	1111	0011

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	WO	n/a	WO
x	0	1	-	WO	WO	WO
x	1	1	-	n/a	WO	WO

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \&\& (HCR_EL2.E2H == 0)$:
 - If $HCR_EL2.TTLB == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
 - If $HSTR_EL2.T8 == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \&\& (HCR_EL2.E2H == 1) \&\& (HCR_EL2.TGE == 0)$:
 - If $HCR_EL2.TTLB == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
 - If $HSTR_EL2.T8 == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $HCR.TTLB == 1$, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
 - If $HSTR.T8 == 1$, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

G6.2.132 TLBIALLNSNH, TLB Invalidate All, Non-Secure Non-Hyp

The TLBIALLNSNH characteristics are:

Purpose

If EL2 is implemented, invalidate all cached copies of translation table entries from TLBs that are from any level of the translation table walk that would be required for stage 1 or stage 2 of the Non-secure PL1&0 translation regime, regardless of the associated VMID.

The invalidation only applies to the PE that executes this instruction.

Configurations

There are no configuration notes.

Attributes

TLBIALLNSNH is a 32-bit System instruction.

Field descriptions

TLBIALLNSNH ignores the value in the register specified by the instruction. Software does not have to write a value to the register before issuing this instruction.

Executing the TLBIALLNSNH instruction

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 4, <Rt>, c8, c7, 4	100	100	1000	1111	0111

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	WO
x	0	1	-	-	WO	WO
x	1	1	-	n/a	WO	WO

If EL2 is not implemented, this instruction is UNDEFINED.

If this instruction is executed in a Secure privileged mode other than Monitor mode, then the behavior is CONSTRAINED UNPREDICTABLE, and one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The instruction executes as if it had been executed in Monitor mode.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \&\& (HCR_EL2.E2H == 0)$:
 - If $HSTR_EL2.T8 == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \&\& (HCR_EL2.E2H == 1) \&\& (HCR_EL2.TGE == 0)$:
 - If $HSTR_EL2.T8 == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $HSTR.T8 == 1$, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

G6.2.133 TLBIALLNSNHIS, TLB Invalidate All, Non-Secure Non-Hyp, Inner Shareable

The TLBIALLNSNHIS characteristics are:

Purpose

If EL2 is implemented, invalidate all cached copies of translation table entries from TLBs that are from any level of the translation table walk that would be required for stage 1 or stage 2 of the Non-secure PL1&0 translation regime, regardless of the associated VMID.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this instructions.

Configurations

There are no configuration notes.

Attributes

TLBIALLNSNHIS is a 32-bit System instruction.

Field descriptions

TLBIALLNSNHIS ignores the value in the register specified by the instruction. Software does not have to write a value to the register before issuing this instruction.

Executing the TLBIALLNSNHIS instruction

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 4, <Rt>, c8, c3, 4	100	100	1000	1111	0011

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	WO
x	0	1	-	-	WO	WO
x	1	1	-	n/a	WO	WO

If EL2 is not implemented, this instruction is UNDEFINED.

If this instruction is executed in a Secure privileged mode other than Monitor mode, then the behavior is CONSTRAINED UNPREDICTABLE, and one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The instruction executes as if it had been executed in Monitor mode.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \&\& (HCR_EL2.E2H == 0)$:
 - If $HSTR_EL2.T8 == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \&\& (HCR_EL2.E2H == 1) \&\& (HCR_EL2.TGE == 0)$:
 - If $HSTR_EL2.T8 == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $HSTR.T8 == 1$, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

G6.2.134 TLBIASID, TLB Invalidate by ASID match

The TLBIASID characteristics are:

Purpose

Invalidate all cached copies of translation table entries from TLBs that meet the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used for the specified ASID, and either:
 - Is from a level of lookup above the final level.
 - Is a non-global entry from the final level of lookup.
- If EL2 is implemented, the entry would be used with the current VMID.

From the entries that match these requirement, the entries that are invalidated are required for the following translation regime:

- If executed at Secure EL1 when EL3 is using AArch64, the Secure EL1&0 translation regime.
- If executed in Secure state when EL3 is using AArch32, the Secure PL1&0 translation regime.
- If executed in Non-secure state, the Non-secure PL1&0 translation regime.

The invalidation only applies to the PE that executes this instruction.

Configurations

There are no configuration notes.

Attributes

TLBIASID is a 32-bit System instruction.

Field descriptions

The TLBIASID input value bit assignments are:

Bits [31:8]

Reserved, RES0.

ASID, bits [7:0]

ASID value to match. Any TLB entries for non-global pages that match the ASID values will be affected by this operation.

Executing the TLBIASID instruction

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c8, c7, 2	000	010	1000	1111	0111

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	WO	n/a	WO
x	0	1	-	WO	WO	WO
x	1	1	-	n/a	WO	WO

When `HCR.FB` is 1, at Non-secure EL1 this instruction executes as a `TLBIASIDIS`.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 0)$:
 - If $HCR_EL2.TTLB == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
 - If $HSTR_EL2.T8 == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 1) \ \&\& \ (HCR_EL2.TGE == 0)$:
 - If $HCR_EL2.TTLB == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
 - If $HSTR_EL2.T8 == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $HCR.TTLB == 1$, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
 - If $HSTR.T8 == 1$, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

G6.2.135 TLBIASIDIS, TLB Invalidate by ASID match, Inner Shareable

The TLBIASIDIS characteristics are:

Purpose

Invalidate all cached copies of translation table entries from TLBs that meet the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used for the specified ASID, and either:
 - Is from a level of lookup above the final level.
 - Is a non-global entry from the final level of lookup.
- If EL2 is implemented, the entry would be used with the current VMID.

From the entries that match these requirement, the entries that are invalidated are required for the following translation regime:

- If executed at Secure EL1 when EL3 is using AArch64, the Secure EL1&0 translation regime.
- If executed in Secure state when EL3 is using AArch32, the Secure PL1&0 translation regime.
- If executed in Non-secure state, the Non-secure PL1&0 translation regime.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this instructions.

Configurations

There are no configuration notes.

Attributes

TLBIASIDIS is a 32-bit System instruction.

Field descriptions

The TLBIASIDIS input value bit assignments are:

Bits [31:8]

Reserved, RES0.

ASID, bits [7:0]

ASID value to match. Any TLB entries for non-global pages that match the ASID values will be affected by this operation.

Executing the TLBIASIDIS instruction

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c8, c3, 2	000	010	1000	1111	0011

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	WO	n/a	WO
x	0	1	-	WO	WO	WO
x	1	1	-	n/a	WO	WO

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
 - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
 - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HCR.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
 - If HSTR.T8==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

G6.2.136 TLBIIPAS2, TLB Invalidate by Intermediate Physical Address, Stage 2

The TLBIIPAS2 characteristics are:

Purpose

If EL2 is implemented, invalidate all cached copies of translation table entries from TLBs that meet the following requirements:

- The entry is a stage 2 only translation table entry, from any level of the translation table walk.
- SCR.NS is 1.
- The entry would be used for the specified IPA.
- The entry would be used with the current VMID.
- The entry would be required for the PL1&0 translation regime.

The invalidation is not required to apply to caching structures that combine stage 1 and stage 2 translation table entries.

The invalidation only applies to the PE that executes this instruction.

Configurations

———— Note ————

This System instruction is not implemented in architecture versions before ARMv8.

Attributes

TLBIIPAS2 is a 32-bit System instruction.

Field descriptions

The TLBIIPAS2 input value bit assignments are:

31	28 27	0
RES0	IPA[39:12]	

Bits [31:28]

Reserved, RES0.

IPA[39:12], bits [27:0]

Bits[39:12] of the intermediate physical address to match.

Executing the TLBIIPAS2 instruction

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 4, <Rt>, c8, c4, 1	100	001	1000	1111	0100

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	WO
x	0	1	-	-	WO	WO
x	1	1	-	n/a	WO	WO

If EL2 is not implemented, this instruction is UNDEFINED.

If SCR.NS is 0, this instruction is a NOP.

If this instruction is executed in a Secure privileged mode other than Monitor mode, then the behavior is CONSTRAINED UNPREDICTABLE, and one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The instruction executes as if it had been executed in Monitor mode.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HSTR.T8==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

G6.2.137 TLBIIPAS2IS, TLB Invalidate by Intermediate Physical Address, Stage 2, Inner Shareable

The TLBIIPAS2IS characteristics are:

Purpose

If EL2 is implemented, invalidate all cached copies of translation table entries from TLBs that meet the following requirements:

- The entry is a stage 2 only translation table entry, from any level of the translation table walk.
- SCR.NS is 1.
- The entry would be used for the specified IPA.
- The entry would be used with the current VMID.
- The entry would be required for the PL1&0 translation regime.

The invalidation is not required to apply to caching structures that combine stage 1 and stage 2 translation table entries.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this instructions.

Configurations

———— Note ————

This System instruction is not implemented in architecture versions before ARMv8.

Attributes

TLBIIPAS2IS is a 32-bit System instruction.

Field descriptions

The TLBIIPAS2IS input value bit assignments are:

31	28 27	0
RES0	IPA[39:12]	

Bits [31:28]

Reserved, RES0.

IPA[39:12], bits [27:0]

Bits[39:12] of the intermediate physical address to match.

Executing the TLBIIPAS2IS instruction

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 4, <Rt>, c8, c0, 1	100	001	1000	1111	0000

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	WO
x	0	1	-	-	WO	WO
x	1	1	-	n/a	WO	WO

If EL2 is not implemented, this instruction is UNDEFINED.

If SCR.NS is 0, this instruction is a NOP.

If this instruction is executed in a Secure privileged mode other than Monitor mode, then the behavior is CONSTRAINED UNPREDICTABLE, and one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The instruction executes as if it had been executed in Monitor mode.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HSTR.T8==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

G6.2.138 TLBIIPAS2L, TLB Invalidate by Intermediate Physical Address, Stage 2, Last level

The TLBIIPAS2L characteristics are:

Purpose

If EL2 is implemented, invalidate all cached copies of translation table entries from TLBs that meet the following requirements:

- The entry is a stage 2 only translation table entry, from the final level of the translation table walk.
- SCR.NS is 1.
- The entry would be used for the specified IPA.
- The entry would be used with the current VMID.
- The entry would be required for the PL1&0 translation regime.

The invalidation is not required to apply to caching structures that combine stage 1 and stage 2 translation table entries.

The invalidation only applies to the PE that executes this instruction.

Configurations

———— Note ————

This System instruction is not implemented in architecture versions before ARMv8.

Attributes

TLBIIPAS2L is a 32-bit System instruction.

Field descriptions

The TLBIIPAS2L input value bit assignments are:

31	28 27	0
RES0	IPA[39:12]	

Bits [31:28]

Reserved, RES0.

IPA[39:12], bits [27:0]

Bits[39:12] of the intermediate physical address to match.

Executing the TLBIIPAS2L instruction

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 4, <Rt>, c8, c4, 5	100	101	1000	1111	0100

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	WO
x	0	1	-	-	WO	WO
x	1	1	-	n/a	WO	WO

If EL2 is not implemented, this instruction is UNDEFINED.

If SCR.NS is 0, this instruction is a NOP.

If this instruction is executed in a Secure privileged mode other than Monitor mode, then the behavior is CONSTRAINED UNPREDICTABLE, and one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The instruction executes as if it had been executed in Monitor mode.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HSTR.T8==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

G6.2.139 TLBIIPAS2LIS, TLB Invalidate by Intermediate Physical Address, Stage 2, Last level, Inner Shareable

The TLBIIPAS2LIS characteristics are:

Purpose

If EL2 is implemented, invalidate all cached copies of translation table entries from TLBs that meet the following requirements:

- The entry is a stage 2 only translation table entry, from the final level of the translation table walk.
- SCR.NS is 1.
- The entry would be used for the specified IPA.
- The entry would be used with the current VMID.
- The entry would be required for the PL1&0 translation regime.

The invalidation is not required to apply to caching structures that combine stage 1 and stage 2 translation table entries.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this instructions.

Configurations

Note

This System instruction is not implemented in architecture versions before ARMv8.

Attributes

TLBIIPAS2LIS is a 32-bit System instruction.

Field descriptions

The TLBIIPAS2LIS input value bit assignments are:

Bits [31:28]

Reserved, RES0.

IPA[39:12], bits [27:0]

Bits[39:12] of the intermediate physical address to match.

Executing the TLBIIPAS2LIS instruction

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 4, <Rt>, c8, c0, 5	100	101	1000	1111	0000

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	WO
x	0	1	-	-	WO	WO
x	1	1	-	n/a	WO	WO

If EL2 is not implemented, this instruction is UNDEFINED.

If SCR.NS is 0, this instruction is a NOP.

If this instruction is executed in a Secure privileged mode other than Monitor mode, then the behavior is CONSTRAINED UNPREDICTABLE, and one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The instruction executes as if it had been executed in Monitor mode.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HSTR.T8==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

G6.2.140 TLBIMVA, TLB Invalidate by VA

The TLBIMVA characteristics are:

Purpose

Invalidate all cached copies of translation table entries from TLBs that meet the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified address, and one of the following applies:
 - The entry is from a level of lookup above the final level and matches the specified ASID.
 - The entry is a global entry from the final level of lookup.
 - The entry is a non-global entry from the final level of lookup that matches the specified ASID.
- If EL2 is implemented, the entry would be used with the current VMID.

From the entries that match these requirement, the entries that are invalidated are required for the following translation regime:

- If executed at Secure EL1 when EL3 is using AArch64, the Secure EL1&0 translation regime.
- If executed in Secure state when EL3 is using AArch32, the Secure PL1&0 translation regime.
- If executed in Non-secure state, the Non-secure PL1&0 translation regime.

The invalidation only applies to the PE that executes this instruction.

Configurations

There are no configuration notes.

Attributes

TLBIMVA is a 32-bit System instruction.

Field descriptions

The TLBIMVA input value bit assignments are:

VA, bits [31:12]

Virtual address to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Bits [11:8]

Reserved, RES0.

ASID, bits [7:0]

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Global TLB entries that match the VA value will be affected by this operation, regardless of the value of the ASID field.

Executing the TLBIMVA instruction

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c8, c7, 1	000	001	1000	1111	0111

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	WO	n/a	WO
x	0	1	-	WO	WO	WO
x	1	1	-	n/a	WO	WO

When [HCR.FB](#) is 1, at Non-secure EL1 this instruction executes as a [TLBIMVAIS](#).

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If [HCR_EL2.TTLB](#)==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
 - If [HSTR_EL2.T8](#)==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If [HCR_EL2.TTLB](#)==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
 - If [HSTR_EL2.T8](#)==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If [HCR.TTLB](#)==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
 - If [HSTR.T8](#)==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

G6.2.141 TLBIMVAA, TLB Invalidate by VA, All ASID

The TLBIMVAA characteristics are:

Purpose

Invalidate all cached copies of translation table entries from TLBs that meet the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.
- The entry would be used to translate the specified address.
- If EL2 is implemented, the entry would be used with the current VMID.

From the entries that match these requirement, the entries that are invalidated are required for the following translation regime:

- If executed at Secure EL1 when EL3 is using AArch64, the Secure EL1&0 translation regime.
- If executed in Secure state when EL3 is using AArch32, the Secure PL1&0 translation regime.
- If executed in Non-secure state, the Non-secure PL1&0 translation regime.

The invalidation only applies to the PE that executes this instruction.

Configurations

There are no configuration notes.

Attributes

TLBIMVAA is a 32-bit System instruction.

Field descriptions

The TLBIMVAA input value bit assignments are:

VA, bits [31:12]

Virtual address to match. Any unlocked TLB entries that match the VA will be affected by this operation, regardless of the ASID.

Bits [11:0]

Reserved, RES0.

Executing the TLBIMVAA instruction

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c8, c7, 3	000	011	1000	1111	0111

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	WO	n/a	WO
x	0	1	-	WO	WO	WO
x	1	1	-	n/a	WO	WO

When [HCR.FB](#) is 1, at Non-secure EL1 this instruction executes as a [TLBIMVAAIS](#).

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 0)$:
 - If $HCR_EL2.TTLB == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
 - If $HSTR_EL2.T8 == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 1) \ \&\& \ (HCR_EL2.TGE == 0)$:
 - If $HCR_EL2.TTLB == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
 - If $HSTR_EL2.T8 == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $HCR.TTLB == 1$, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
 - If $HSTR.T8 == 1$, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

G6.2.142 TLBIMVAAIS, TLB Invalidate by VA, All ASID, Inner Shareable

The TLBIMVAAIS characteristics are:

Purpose

Invalidate all cached copies of translation table entries from TLBs that meet the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.
- The entry would be used to translate the specified address.
- If EL2 is implemented, the entry would be used with the current VMID.

From the entries that match these requirement, the entries that are invalidated are required for the following translation regime:

- If executed at Secure EL1 when EL3 is using AArch64, the Secure EL1&0 translation regime.
- If executed in Secure state when EL3 is using AArch32, the Secure PL1&0 translation regime.
- If executed in Non-secure state, the Non-secure PL1&0 translation regime.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this instructions.

Configurations

There are no configuration notes.

Attributes

TLBIMVAAIS is a 32-bit System instruction.

Field descriptions

The TLBIMVAAIS input value bit assignments are:

VA, bits [31:12]

Virtual address to match. Any unlocked TLB entries that match the VA will be affected by this operation, regardless of the ASID.

Bits [11:0]

Reserved, RES0.

Executing the TLBIMVAAIS instruction

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c8, c3, 3	000	011	1000	1111	0011

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	WO	n/a	WO
x	0	1	-	WO	WO	WO
x	1	1	-	n/a	WO	WO

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
 - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
 - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HCR.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
 - If HSTR.T8==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

G6.2.143 TLBIMVAAL, TLB Invalidate by VA, All ASID, Last level

The TLBIMVAAL characteristics are:

Purpose

Invalidate all cached copies of translation table entries from TLBs that meet the following requirements:

- The entry is a stage 1 translation table entry, from the final level of the translation table walk.
- The entry would be used to translate the specified address.
- If EL2 is implemented, the entry would be used with the current VMID.

From the entries that match these requirement, the entries that are invalidated are required for the following translation regime:

- If executed at Secure EL1 when EL3 is using AArch64, the Secure EL1&0 translation regime.
- If executed in Secure state when EL3 is using AArch32, the Secure PL1&0 translation regime.
- If executed in Non-secure state, the Non-secure PL1&0 translation regime.

The invalidation only applies to the PE that executes this instruction.

Configurations

———— Note ————

This System instruction is not implemented in architecture versions before ARMv8.

Attributes

TLBIMVAAL is a 32-bit System instruction.

Field descriptions

The TLBIMVAAL input value bit assignments are:

VA, bits [31:12]

Virtual address to match. Any unlocked TLB entries that match the VA will be affected by this operation, regardless of the ASID.

Bits [11:0]

Reserved, RES0.

Executing the TLBIMVAAL instruction

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c8, c7, 7	000	111	1000	1111	0111

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	WO	n/a	WO
x	0	1	-	WO	WO	WO
x	1	1	-	n/a	WO	WO

When `HCR.FB` is 1, at Non-secure EL1 this instruction executes as a `TLBIMVAALIS`.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 0)$:
 - If $HCR_EL2.TTLB == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
 - If $HSTR_EL2.T8 == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 1) \ \&\& \ (HCR_EL2.TGE == 0)$:
 - If $HCR_EL2.TTLB == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
 - If $HSTR_EL2.T8 == 1$, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $HCR.TTLB == 1$, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
 - If $HSTR.T8 == 1$, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

G6.2.144 TLBIMVAALIS, TLB Invalidate by VA, All ASID, Last level, Inner Shareable

The TLBIMVAALIS characteristics are:

Purpose

Invalidate all cached copies of translation table entries from TLBs that meet the following requirements:

- The entry is a stage 1 translation table entry, from the final level of the translation table walk.
- The entry would be used to translate the specified address.
- If EL2 is implemented, the entry would be used with the current VMID.

From the entries that match these requirement, the entries that are invalidated are required for the following translation regime:

- If executed at Secure EL1 when EL3 is using AArch64, the Secure EL1&0 translation regime.
- If executed in Secure state when EL3 is using AArch32, the Secure PL1&0 translation regime.
- If executed in Non-secure state, the Non-secure PL1&0 translation regime.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this instructions.

Configurations

———— **Note** —————

This System instruction is not implemented in architecture versions before ARMv8.

Attributes

TLBIMVAALIS is a 32-bit System instruction.

Field descriptions

The TLBIMVAALIS input value bit assignments are:

VA, bits [31:12]

Virtual address to match. Any unlocked TLB entries that match the VA will be affected by this operation, regardless of the ASID.

Bits [11:0]

Reserved, RES0.

Executing the TLBIMVAALIS instruction

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c8, c3, 7	000	111	1000	1111	0011

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	WO	n/a	WO
x	0	1	-	WO	WO	WO
x	1	1	-	n/a	WO	WO

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
 - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
 - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HCR.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
 - If HSTR.T8==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

G6.2.145 TLBIMVAH, TLB Invalidate by VA, Hyp mode

The TLBIMVAH characteristics are:

Purpose

If EL2 is implemented, invalidate all cached copies of translation table entries from TLBs that are from any level of the translation table walk that would be required for the Non-secure EL2 translation regime and used to translate the specified address.

The invalidation only applies to the PE that executes this instruction.

Configurations

There are no configuration notes.

Attributes

TLBIMVAH is a 32-bit System instruction.

Field descriptions

The TLBIMVAH input value bit assignments are:

VA, bits [31:12]

Virtual address to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Bits [11:0]

Reserved, RES0.

Executing the TLBIMVAH instruction

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 4, <Rt>, c8, c7, 1	100	001	1000	1111	0111

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	WO
x	0	1	-	-	WO	WO
x	1	1	-	n/a	WO	WO

If EL2 is not implemented, this instruction is UNDEFINED.

If this instruction is executed in a Secure privileged mode other than Monitor mode, then the behavior is CONSTRAINED UNPREDICTABLE, and one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The instruction executes as if it had been executed in Monitor mode.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If [HSTR_EL2.T8](#)==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If [HSTR_EL2.T8](#)==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If [HSTR.T8](#)==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

G6.2.146 TLBIMVAHIS, TLB Invalidate by VA, Hyp mode, Inner Shareable

The TLBIMVAHIS characteristics are:

Purpose

If EL2 is implemented, invalidate all cached copies of translation table entries from TLBs that are from any level of the translation table walk that would be required for the Non-secure EL2 translation regime and used to translate the specified address.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this instructions.

Configurations

There are no configuration notes.

Attributes

TLBIMVAHIS is a 32-bit System instruction.

Field descriptions

The TLBIMVAHIS input value bit assignments are:

VA, bits [31:12]

Virtual address to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Bits [11:0]

Reserved, RES0.

Executing the TLBIMVAHIS instruction

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 4, <Rt>, c8, c3, 1	100	001	1000	1111	0011

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	WO
x	0	1	-	-	WO	WO
x	1	1	-	n/a	WO	WO

If EL2 is not implemented, this instruction is UNDEFINED.

If this instruction is executed in a Secure privileged mode other than Monitor mode, then the behavior is CONSTRAINED UNPREDICTABLE, and one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The instruction executes as if it had been executed in Monitor mode.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HSTR.T8==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

G6.2.147 TLBIMVAIS, TLB Invalidate by VA, Inner Shareable

The TLBIMVAIS characteristics are:

Purpose

Invalidate all cached copies of translation table entries from TLBs that meet the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified address, and one of the following applies:
 - The entry is from a level of lookup above the final level and matches the specified ASID.
 - The entry is a global entry from the final level of lookup.
 - The entry is a non-global entry from the final level of lookup that matches the specified ASID.
- If EL2 is implemented, the entry would be used with the current VMID.

From the entries that match these requirement, the entries that are invalidated are required for the following translation regime:

- If executed at Secure EL1 when EL3 is using AArch64, the Secure EL1&0 translation regime.
- If executed in Secure state when EL3 is using AArch32, the Secure PL1&0 translation regime.
- If executed in Non-secure state, the Non-secure PL1&0 translation regime.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this instructions.

Configurations

There are no configuration notes.

Attributes

TLBIMVAIS is a 32-bit System instruction.

Field descriptions

The TLBIMVAIS input value bit assignments are:

VA, bits [31:12]

Virtual address to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Bits [11:8]

Reserved, RES0.

ASID, bits [7:0]

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Global TLB entries that match the VA value will be affected by this operation, regardless of the value of the ASID field.

Executing the TLBIMVAIS instruction

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c8, c3, 1	000	001	1000	1111	0011

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	WO	n/a	WO
x	0	1	-	WO	WO	WO
x	1	1	-	n/a	WO	WO

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
 - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
 - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HCR.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
 - If HSTR.T8==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

G6.2.148 TLBIMVAL, TLB Invalidate by VA, Last level

The TLBIMVAL characteristics are:

Purpose

Invalidate all cached copies of translation table entries from TLBs that meet the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified address, and one of the following applies:
 - The entry is a global entry from the final level of lookup.
 - The entry is a non-global entry from the final level of lookup that matches the specified ASID.
- If EL2 is implemented, the entry would be used with the current VMID.

From the entries that match these requirements, the entries that are invalidated are required for the following translation regime:

- If executed at Secure EL1 when EL3 is using AArch64, the Secure EL1&0 translation regime.
- If executed in Secure state when EL3 is using AArch32, the Secure PL1&0 translation regime.
- If executed in Non-secure state, the Non-secure PL1&0 translation regime.

The invalidation only applies to the PE that executes this instruction.

Configurations

This System instruction is not implemented in architecture versions before ARMv8.

Attributes

TLBIMVAL is a 32-bit System instruction.

Field descriptions

The TLBIMVAL input value bit assignments are:

VA, bits [31:12]

Virtual address to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Bits [11:8]

Reserved, RES0.

ASID, bits [7:0]

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Global TLB entries that match the VA value will be affected by this operation, regardless of the value of the ASID field.

Executing the TLBIMVAL instruction

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c8, c7, 5	000	101	1000	1111	0111

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	WO	n/a	WO
x	0	1	-	WO	WO	WO
x	1	1	-	n/a	WO	WO

When [HCR.FB](#) is 1, at Non-secure EL1 this instruction executes as a [TLBIMVALIS](#).

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If [HCR_EL2.TTLB](#)==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
 - If [HSTR_EL2.T8](#)==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If [HCR_EL2.TTLB](#)==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
 - If [HSTR_EL2.T8](#)==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If [HCR.TTLB](#)==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
 - If [HSTR.T8](#)==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

G6.2.149 TLBINVALH, TLB Invalidate by VA, Last level, Hyp mode

The TLBINVALH characteristics are:

Purpose

If EL2 is implemented, invalidate all cached copies of translation table entries from TLBs that are from the final level of the translation table walk that would be required for the Non-secure EL2 translation regime and used to translate the specified address.

The invalidation only applies to the PE that executes this instruction.

Configurations

This System instruction is not implemented in architecture versions before ARMv8.

Attributes

TLBINVALH is a 32-bit System instruction.

Field descriptions

The TLBINVALH input value bit assignments are:

VA, bits [31:12]

Virtual address to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Bits [11:0]

Reserved, RES0.

Executing the TLBINVALH instruction

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 4, <Rt>, c8, c7, 5	100	101	1000	1111	0111

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	WO
x	0	1	-	-	WO	WO
x	1	1	-	n/a	WO	WO

If this instruction is executed in a Secure privileged mode other than Monitor mode, then the behavior is CONSTRAINED UNPREDICTABLE, and one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The instruction executes as if it had been executed in Monitor mode.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HSTR.T8==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

G6.2.150 TLBINVALHIS, TLB Invalidate by VA, Last level, Hyp mode, Inner Shareable

The TLBINVALHIS characteristics are:

Purpose

If EL2 is implemented, invalidate all cached copies of translation table entries from TLBs that are from the final level of the translation table walk that would be required for the Non-secure EL2 translation regime and used to translate the specified address.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this instructions.

Configurations

This System instruction is not implemented in architecture versions before ARMv8.

Attributes

TLBINVALHIS is a 32-bit System instruction.

Field descriptions

The TLBINVALHIS input value bit assignments are:

VA, bits [31:12]

Virtual address to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Bits [11:0]

Reserved, RES0.

Executing the TLBINVALHIS instruction

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 4, <Rt>, c8, c3, 5	100	101	1000	1111	0011

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	WO
x	0	1	-	-	WO	WO
x	1	1	-	n/a	WO	WO

If EL2 is not implemented, this instruction is UNDEFINED.

If this instruction is executed in a Secure privileged mode other than Monitor mode, then the behavior is CONSTRAINED UNPREDICTABLE, and one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The instruction executes as if it had been executed in Monitor mode.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HSTR.T8==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

G6.2.151 TLBINVALIS, TLB Invalidate by VA, Last level, Inner Shareable

The TLBINVALIS characteristics are:

Purpose

Invalidate all cached copies of translation table entries from TLBs that meet the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified address, and one of the following applies:
 - The entry is a global entry from the final level of lookup.
 - The entry is a non-global entry from the final level of lookup that matches the specified ASID.
- If EL2 is implemented, the entry would be used with the current VMID.

From the entries that match these requirements, the entries that are invalidated are required for the following translation regime:

- If executed at Secure EL1 when EL3 is using AArch64, the Secure EL1&0 translation regime.
- If executed in Secure state when EL3 is using AArch32, the Secure PL1&0 translation regime.
- If executed in Non-secure state, the Non-secure PL1&0 translation regime.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this instructions.

Configurations

This System instruction is not implemented in architecture versions before ARMv8.

Attributes

TLBINVALIS is a 32-bit System instruction.

Field descriptions

The TLBINVALIS input value bit assignments are:

VA, bits [31:12]

Virtual address to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Bits [11:8]

Reserved, RES0.

ASID, bits [7:0]

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Global TLB entries that match the VA value will be affected by this operation, regardless of the value of the ASID field.

Executing the TLBIMVALIS instruction

This instruction is executed using MCR with the following syntax:

MCR <syntax>

This syntax uses the following encoding in the System instruction encoding space:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c8, c3, 5	000	101	1000	1111	0011

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	WO	n/a	WO
x	0	1	-	WO	WO	WO
x	1	1	-	n/a	WO	WO

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
 - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
 - If HSTR_EL2.T8==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HCR.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
 - If HSTR.T8==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.

G6.2.152 TLBTR, TLB Type Register

The TLBTR characteristics are:

Purpose

Provides information about the TLB implementation. The register must define whether the implementation provides separate instruction and data TLBs, or a unified TLB. Normally, the IMPLEMENTATION DEFINED information in this register includes the number of lockable entries in the TLB.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

Attributes

TLBTR is a 32-bit register.

Field descriptions

The TLBTR bit assignments are:

IMPLEMENTATION DEFINED, bits [31:1]

IMPLEMENTATION DEFINED.

nU, bit [0]

Not Unified TLB. Indicates whether the implementation has a unified TLB:

- 0 Unified TLB.
- 1 Separate Instruction and Data TLBs.

Accessing the TLBTR

This register can be read using MRC with the following syntax:

MRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c0, c0, 3	000	011	0000	1111	0000

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	RO	n/a	RO
x	0	1	-	RO	RO	RO
x	1	1	-	n/a	RO	RO

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If HCR_EL2.TID1==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If HCR_EL2.TID1==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If HSTR_EL2.T0==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HCR.TID1==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
 - If HSTR.T0==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.

G6.2.153 TPIDRPRW, PL1 Software Thread ID Register

The TPIDRPRW characteristics are:

Purpose

Provides a location where software executing at EL1 or higher can store thread identifying information that is not visible to software executing at EL0, for OS management purposes.

The PE makes no use of this register.

Configurations

AArch32 System register TPIDRPRW is architecturally mapped to AArch64 System register [TPIDR_EL1](#)[31:0].

The PE never updates this register. This means the register is always UNKNOWN on reset.

Attributes

TPIDRPRW is a 32-bit register.

Field descriptions

The TPIDRPRW bit assignments are:

Bits [31:0]

Thread ID. Thread identifying information stored by software running at this Exception level.

Accessing the TPIDRPRW

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c13, c0, 4	000	100	1101	1111	0000

Accessibility

The register is accessible in software as follows:

Configuration	Control			Accessibility				Instance
	E2H	TGE	NS	EL0	EL1	EL2	EL3	
EL3 is using AArch32.	x	x	0	-	n/a	n/a	RW	TPIDRPRW_s
EL3 is not implemented.	x	x	0	-	RW	n/a	n/a	TPIDRPRW
EL3 is not implemented.	x	0	1	-	RW	RW	n/a	TPIDRPRW
EL3 is not implemented.	x	1	1	-	n/a	RW	n/a	TPIDRPRW
EL3 is using AArch64.	x	x	0	-	RW	n/a	n/a	TPIDRPRW
EL3 is using AArch64.	x	0	1	-	RW	RW	n/a	TPIDRPRW
EL3 is using AArch64.	x	1	1	-	n/a	RW	n/a	TPIDRPRW
EL3 is using AArch32.	x	0	1	-	RW	RW	RW	TPIDRPRW_ns
EL3 is using AArch32.	x	1	1	-	n/a	RW	RW	TPIDRPRW_ns

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If HSTR_EL2.T13==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If HSTR_EL2.T13==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HSTR.T13==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

G6.2.154 TPIDRURO, PL0 Read-Only Software Thread ID Register

The TPIDRURO characteristics are:

Purpose

Provides a location where software executing at EL1 or higher can store thread identifying information that is visible to software executing at EL0, for OS management purposes.

The PE makes no use of this register.

Configurations

AArch32 System register TPIDRURO is architecturally mapped to AArch64 System register [TPIDRRO_EL0](#)[31:0].

The PE never updates this register. This means the register is always UNKNOWN on reset.

Attributes

TPIDRURO is a 32-bit register.

Field descriptions

The TPIDRURO bit assignments are:

Bits [31:0]

Thread ID. Thread identifying information stored by software running at this Exception level.

Accessing the TPIDRURO

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c13, c0, 3	000	011	1101	1111	0000

Accessibility

The register is accessible in software as follows:

Configuration	Control			Accessibility				Instance
	E2H	TGE	NS	EL0	EL1	EL2	EL3	
EL3 is using AArch32.	x	x	0	RO	n/a	n/a	RW	TPIDRURO_s
EL3 is using AArch32.	x	0	1	RO	RW	RW	RW	TPIDRURO_ns
EL3 is using AArch32.	x	1	1	RO	n/a	RW	RW	TPIDRURO_ns
EL3 is not implemented.	x	x	0	RO	RW	n/a	n/a	TPIDRURO
EL3 is not implemented.	x	0	1	RO	RW	RW	n/a	TPIDRURO
EL3 is not implemented.	x	1	1	RO	n/a	RW	n/a	TPIDRURO
EL3 is using AArch64.	x	x	0	RO	RW	n/a	n/a	TPIDRURO
EL3 is using AArch64.	x	0	1	RO	RW	RW	n/a	TPIDRURO
EL3 is using AArch64.	x	1	1	RO	n/a	RW	n/a	TPIDRURO

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If HSTR_EL2.T13==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If HSTR_EL2.T13==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HSTR.T13==1, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.

G6.2.155 TPIDRURW, PL0 Read/Write Software Thread ID Register

The TPIDRURW characteristics are:

Purpose

Provides a location where software executing at EL0 can store thread identifying information, for OS management purposes.

The PE makes no use of this register.

Configurations

AArch32 System register TPIDRURW is architecturally mapped to AArch64 System register [TPIDR_EL0](#)[31:0].

The PE never updates this register. This means the register is always UNKNOWN on reset.

Attributes

TPIDRURW is a 32-bit register.

Field descriptions

The TPIDRURW bit assignments are:

Bits [31:0]

Thread ID. Thread identifying information stored by software running at this Exception level.

Accessing the TPIDRURW

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c13, c0, 2	000	010	1101	1111	0000

Accessibility

The register is accessible in software as follows:

Configuration	Control			Accessibility				Instance
	E2H	TGE	NS	EL0	EL1	EL2	EL3	
EL3 is using AArch32.	x	x	0	RW	n/a	n/a	RW	TPIDRURW_s
EL3 is using AArch32.	x	0	1	RW	RW	RW	RW	TPIDRURW_ns
EL3 is using AArch32.	x	1	1	RW	n/a	RW	RW	TPIDRURW_ns
EL3 is not implemented.	x	x	0	RW	RW	n/a	n/a	TPIDRURW
EL3 is not implemented.	x	0	1	RW	RW	RW	n/a	TPIDRURW
EL3 is not implemented.	x	1	1	RW	n/a	RW	n/a	TPIDRURW
EL3 is using AArch64.	x	x	0	RW	RW	n/a	n/a	TPIDRURW
EL3 is using AArch64.	x	0	1	RW	RW	RW	n/a	TPIDRURW
EL3 is using AArch64.	x	1	1	RW	n/a	RW	n/a	TPIDRURW

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If HSTR_EL2.T13==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If HSTR_EL2.T13==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HSTR.T13==1, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.

G6.2.156 TTBCR, Translation Table Base Control Register

The TTBCR characteristics are:

Purpose

The control register for stage 1 of the PL1&0 translation regime. Its controls include:

- Where the VA range is split between addresses translated using [TTBR0](#) and addresses translated using [TTBR1](#).
- The translation table format used by this stage of translation.

In ARMv8.2, when the value of TTBCR.{EAE, T2E} is {1,1}, TTBCR is used with [TTBCR2](#).

Configurations

AArch32 System register TTBCR is architecturally mapped to AArch64 System register [TCR_EL1](#)[31:0].

The current translation table format determines which format of the register is used.

When EL3 is using AArch32, write access to TTBCR(S) is disabled when the CP15SDISABLE signal is asserted HIGH.

Some RW fields of this register have defined reset values. These apply only if the PE resets into an Exception level that is using AArch32. If the PE resets into EL3 using AArch32 then:

- The EAE bit resets to 0 in both the Secure and the Non-secure instances of the register.
- Other reset values apply only to the Secure instance of the register.

Attributes

TTBCR is a 32-bit register.

Field descriptions

The TTBCR bit assignments are:

For all register layouts:

EAE, bit [31]

Extended Address Enable. The meanings of the possible values of this bit are:

- | | |
|---|--|
| 0 | Use the VMSAv8-32 translation system with the Short-descriptor translation table format. |
| 1 | Use the VMSAv8-32 translation system with the Long-descriptor translation table format. |

When TTBCR.EAE==0:

EAE, bit [31]

Extended Address Enable. The meanings of the possible values of this bit are:

- | | |
|---|--|
| 0 | Use the VMSAv8-32 translation system with the Short-descriptor translation table format. |
|---|--|

When this register has an architecturally-defined reset value, this field resets to 0.

Bits [30:6]

Reserved, RES0.

PD1, bit [5]

Translation table walk disable for translations using **TTBR1**. This bit controls whether a translation table walk is performed on a TLB miss, for an address that is translated using **TTBR1**. The encoding of this bit is:

- 0 Perform translation table walks using **TTBR1**.
- 1 A TLB miss on an address that is translated using **TTBR1** generates a Translation fault. No translation table walk is performed.

When this register has an architecturally-defined reset value, this field resets to 0.

PD0, bit [4]

Translation table walk disable for translations using **TTBR0**. This bit controls whether a translation table walk is performed on a TLB miss for an address that is translated using **TTBR0**. The encoding of this bit is:

- 0 Perform translation table walks using **TTBR0**.
- 1 A TLB miss on an address that is translated using **TTBR0** generates a Translation fault. No translation table walk is performed.

When this register has an architecturally-defined reset value, this field resets to 0.

Bit [3]

Reserved, RES0.

N, bits [2:0]

Indicate the width of the base address held in **TTBR0**. In **TTBR0**, the base address field is bits[31:14-N]. The value of N also determines:

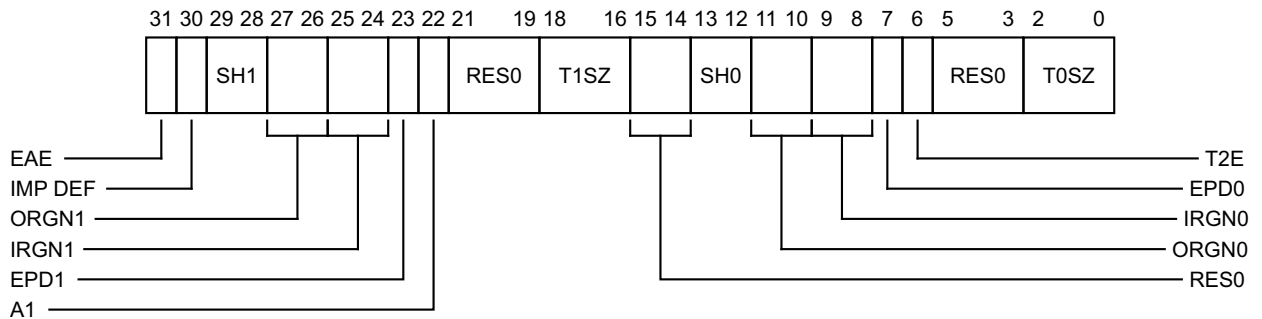

- Whether **TTBR0** or **TTBR1** is used as the base address for translation table walks.
- The size of the translation table pointed to by **TTBR0**.

N can take any value from 0 to 7, that is, from 0b000 to 0b111.

When N has its reset value of 0, the translation table base is compatible with ARMv5 and ARMv6.

When this register has an architecturally-defined reset value, this field resets to 0.

When TTBCR.EAE==1:

EAE, bit [31]

Extended Address Enable. The meanings of the possible values of this bit are:

- 1 Use the VMSAv8-32 translation system with the Long-descriptor translation table format.

When this register has an architecturally-defined reset value, this field resets to 0.

IMP DEF, bit [30]

IMPLEMENTATION DEFINED.

When this register has an architecturally-defined reset value, this field resets to 0.

SH1, bits [29:28]

Shareability attribute for memory associated with translation table walks using [TTBR1](#). Defined values are:

00	Non-shareable
10	Outer Shareable
11	Inner Shareable

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is CONstrained UNPREDICTABLE, as described in [Reserved values in System and memory-mapped registers and translation table entries on page K1-6117](#).

When this register has an architecturally-defined reset value, this field resets to 0.

ORGN1, bits [27:26]

Outer cacheability attribute for memory associated with translation table walks using [TTBR1](#).

00	Normal memory, Outer Non-cacheable
01	Normal memory, Outer Write-Back Read-Allocate Write-Allocate Cacheable
10	Normal memory, Outer Write-Through Read-Allocate No Write-Allocate Cacheable
11	Normal memory, Outer Write-Back Read-Allocate No Write-Allocate Cacheable

When this register has an architecturally-defined reset value, this field resets to 0.

IRGN1, bits [25:24]

Inner cacheability attribute for memory associated with translation table walks using [TTBR1](#).

00	Normal memory, Inner Non-cacheable
01	Normal memory, Inner Write-Back Read-Allocate Write-Allocate Cacheable
10	Normal memory, Inner Write-Through Read-Allocate No Write-Allocate Cacheable
11	Normal memory, Inner Write-Back Read-Allocate No Write-Allocate Cacheable

When this register has an architecturally-defined reset value, this field resets to 0.

EPD1, bit [23]

Translation table walk disable for translations using [TTBR1](#). This bit controls whether a translation table walk is performed on a TLB miss, for an address that is translated using [TTBR1](#). The encoding of this bit is:

0	Perform translation table walks using TTBR1 .
1	A TLB miss on an address that is translated using TTBR1 generates a Translation fault. No translation table walk is performed.

When this register has an architecturally-defined reset value, this field resets to 0.

A1, bit [22]

Selects whether [TTBR0](#) or [TTBR1](#) defines the ASID. The encoding of this bit is:

0	TTBR0 .ASID defines the ASID.
1	TTBR1 .ASID defines the ASID.

When this register has an architecturally-defined reset value, this field resets to 0.

Bits [21:19]

Reserved, RES0.

T1SZ, bits [18:16]

See [Selecting between TTBR0 and TTBR1, VMSAv8-32 Long-descriptor translation table format on page G4-4594](#) for how TTBCR.{T1SZ, T0SZ} determine the input address ranges and memory region sizes translated using TTBR0 and TTBR1.

When this register has an architecturally-defined reset value, this field resets to 0.

Bits [15:14]

Reserved, RES0.

SH0, bits [13:12]

Shareability attribute for memory associated with translation table walks using TTBR0.

00	Non-shareable
10	Outer Shareable
11	Inner Shareable

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is CONSTRAINED UNPREDICTABLE, as described in [Reserved values in System and memory-mapped registers and translation table entries on page K1-6117](#).

When this register has an architecturally-defined reset value, this field resets to 0.

ORGN0, bits [11:10]

Outer cacheability attribute for memory associated with translation table walks using TTBR0.

00	Normal memory, Outer Non-cacheable
01	Normal memory, Outer Write-Back Read-Allocate Write-Allocate Cacheable
10	Normal memory, Outer Write-Through Read-Allocate No Write-Allocate Cacheable
11	Normal memory, Outer Write-Back Read-Allocate No Write-Allocate Cacheable

When this register has an architecturally-defined reset value, this field resets to 0.

IRGN0, bits [9:8]

Inner cacheability attribute for memory associated with translation table walks using TTBR0.

00	Normal memory, Inner Non-cacheable
01	Normal memory, Inner Write-Back Read-Allocate Write-Allocate Cacheable
10	Normal memory, Inner Write-Through Read-Allocate No Write-Allocate Cacheable
11	Normal memory, Inner Write-Back Read-Allocate No Write-Allocate Cacheable

When this register has an architecturally-defined reset value, this field resets to 0.

EPD0, bit [7]

Translation table walk disable for translations using TTBR0. This bit controls whether a translation table walk is performed on a TLB miss, for an address that is translated using TTBR0. The encoding of this bit is:

0	Perform translation table walks using TTBR0.
1	A TLB miss on an address that is translated using TTBR0 generates a Translation fault. No translation table walk is performed.

When this register has an architecturally-defined reset value, this field resets to 0.

T2E, bit [6]

In ARMv8.2

TTBCR2 Enable.

Defined values are:

0	TTBCR2 is disabled. The contents of TTBCR2 are treated as 0 for all purposes other than reading or writing the register.
---	--

1 [TTBCR2](#) is enabled.

If `TTBCR.EAE==0`, then the behavior is as if the bit is 0.

This bit is RES0 if [ARMv8.2-AA32HPD](#) is not implemented.

In ARMv8.1 and ARMv8.0.

Reserved, RES0.

Bits [5:3]

Reserved, RES0.

T0SZ, bits [2:0]

See [Selecting between TTBR0 and TTBR1, VMSAv8-32 Long-descriptor translation table format on page G4-4594](#) for how `TTBCR`.{`T1SZ`, `T0SZ`} determine the input address ranges and memory region sizes translated using `TTBR0` and `TTBR1`.

When this register has an architecturally-defined reset value, this field resets to 0.

Accessing the TTBCR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c2, c0, 2	000	010	0010	1111	0000

Accessibility

The register is accessible in software as follows:

Configuration	Control			Accessibility				Instance
	E2H	TGE	NS	EL0	EL1	EL2	EL3	
EL3 is not implemented.	x	x	0	-	RW	n/a	n/a	TTBCR
EL3 is not implemented.	x	0	1	-	RW	RW	n/a	TTBCR
EL3 is not implemented.	x	1	1	-	n/a	RW	n/a	TTBCR
EL3 is using AArch64.	x	x	0	-	RW	n/a	n/a	TTBCR
EL3 is using AArch64.	x	0	1	-	RW	RW	n/a	TTBCR
EL3 is using AArch64.	x	1	1	-	n/a	RW	n/a	TTBCR
EL3 is using AArch32.	x	0	1	-	RW	RW	RW	TTBCR_ns
EL3 is using AArch32.	x	1	1	-	n/a	RW	RW	TTBCR_ns
EL3 is using AArch32.	x	x	0	-	n/a	n/a	RW	TTBCR_s

When EL3 is using AArch32, write access to `TTBCR_s` is UNDEFINED when the `CP15SSDISABLE` signal is asserted HIGH.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 0)$:
 - If $HCR_EL2.TVM == 1$, Non-secure write accesses to this register from EL1 are trapped to EL2.
 - If $HCR_EL2.TRVM == 1$, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If $HSTR_EL2.T2 == 1$, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 1) \ \&\& \ (HCR_EL2.TGE == 0)$:
 - If $HCR_EL2.TVM == 1$, Non-secure write accesses to this register from EL1 are trapped to EL2.
 - If $HCR_EL2.TRVM == 1$, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If $HSTR_EL2.T2 == 1$, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $HCR.TVM == 1$, Non-secure write accesses to this register from EL1 are trapped to Hyp mode.
 - If $HCR.TRVM == 1$, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
 - If $HSTR.T2 == 1$, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

G6.2.157 TTBCR2, Translation Table Base Control Register 2

The TTBCR2 characteristics are:

Purpose

The second control register for stage 1 of the PL1&0 translation regime.

If ARMv8.2-AA32HPD is not implemented and ARMv8.2-TTPBHA is not implemented, then this register is not implemented and its encoding is unallocated. Otherwise:

- When the value of `TTBCR.{EAE, T2E}` is not `{1, 1}`, the contents of TTBCR2 are treated as zero for all purposes other than reading or writing the register.
- When the value of `TTBCR.{EAE, T2E}` is `{1, 1}`, TTBCR2 is used with `TTBCR`.

Configurations

AArch32 System register TTBCR2 is architecturally mapped to AArch64 System register `TCR_EL1[63:32]`.

When EL3 is using AArch32, write access to TTBCR2(S) is disabled when the CP15SDISABLE signal is asserted HIGH.

RW fields in this register reset to architecturally UNKNOWN values.

This register is introduced in ARMv8.2.

Attributes

TTBCR2 is a 32-bit register.

Field descriptions

The TTBCR2 bit assignments are:

Bits [31:19]

Reserved, RES0.

HWU162, bit [18]

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[62] of the stage 1 translation table block or level 3 entry for pages pointed to by `TTBR1` if `TTBCR2.HPD1==1` and `TTBCR.T2E==1`.

Defined values are:

- 0 The stage 1 translation table entry block or level 3 bit cannot be interpreted by hardware for an IMPLEMENTATION DEFINED purpose.
- 1 The stage 1 translation table entry block or level 3 bit can be interpreted by hardware for an IMPLEMENTATION DEFINED purpose if the TTBCR2.HPD1 value is 1.

This bit is RES0 if `ARMv8.2-TTPBHA` is not implemented.

HWU161, bit [17]

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[61] of the stage 1 translation table block or level 3 entry for pages pointed to by [TTBR1](#) if `TTBCR2.HPD1==1` and `TTBCR.T2E==1`.

Defined values are:

- 0 The stage 1 translation table entry block or level 3 bit cannot be interpreted by hardware for an IMPLEMENTATION DEFINED purpose.
- 1 The stage 1 translation table entry block or level 3 bit can be interpreted by hardware for an IMPLEMENTATION DEFINED purpose if the `TTBCR2.HPD1` value is 1.

This bit is RES0 if [ARMv8.2-TTPBHA](#) is not implemented.

HWU160, bit [16]

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[60] of the stage 1 translation table block or level 3 entry for pages pointed to by [TTBR1](#) if `TTBCR2.HPD1==1` and `TTBCR.T2E==1`.

Defined values are:

- 0 The stage 1 translation table entry block or level 3 bit cannot be interpreted by hardware for an IMPLEMENTATION DEFINED purpose.
- 1 The stage 1 translation table entry block or level 3 bit can be interpreted by hardware for an IMPLEMENTATION DEFINED purpose if the `TTBCR2.HPD1` value is 1.

This bit is RES0 if [ARMv8.2-TTPBHA](#) is not implemented.

HWU159, bit [15]

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[59] of the stage 1 translation table block or level 3 entry for pages pointed to by [TTBR1](#) if `TTBCR2.HPD1==1` and `TTBCR.T2E==1`.

Defined values are:

- 0 The stage 1 translation table entry block or level 3 bit cannot be interpreted by hardware for an IMPLEMENTATION DEFINED purpose.
- 1 The stage 1 translation table entry block or level 3 bit can be interpreted by hardware for an IMPLEMENTATION DEFINED purpose if the `TTBCR2.HPD1` value is 1.

This bit is RES0 if [ARMv8.2-TTPBHA](#) is not implemented.

HWU062, bit [14]

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[62] of the stage 1 translation table block or level 3 entry for pages pointed to by [TTBR0](#) if `TTBCR2.HPD0==1` and `TTBCR.T2E==1`.

Defined values are:

- 0 The stage 1 translation table entry block or level 3 bit cannot be interpreted by hardware for an IMPLEMENTATION DEFINED purpose.
- 1 The stage 1 translation table entry block or level 3 bit can be interpreted by hardware for an IMPLEMENTATION DEFINED purpose if the `TTBCR2.HPD0` value is 1.

This bit is RES0 if [ARMv8.2-TTPBHA](#) is not implemented.

HWU061, bit [13]

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[61] of the stage 1 translation table block or level 3 entry for pages pointed to by [TTBR0](#) if `TTBCR2.HPD0==1` and `TTBCR.T2E==1`.

Defined values are:

- 0 The stage 1 translation table entry block or level 3 bit cannot be interpreted by hardware for an IMPLEMENTATION DEFINED purpose.

- 1 The stage 1 translation table entry block or level 3 bit can be interpreted by hardware for an IMPLEMENTATION DEFINED purpose if the TTBCR2.HPD0 value is 1.

This bit is RES0 if [ARMv8.2-TTPBHA](#) is not implemented.

HWU060, bit [12]

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[60] of the stage 1 translation table block or level 3 entry for pages pointed to by [TTBR0](#) if TTBCR2.HPD0==1 and [TTBCR.T2E](#)==1.

Defined values are:

- 0 The stage 1 translation table entry block or level 3 bit cannot be interpreted by hardware for an IMPLEMENTATION DEFINED purpose.
- 1 The stage 1 translation table entry block or level 3 bit can be interpreted by hardware for an IMPLEMENTATION DEFINED purpose if the TTBCR2.HPD0 value is 1.

This bit is RES0 if [ARMv8.2-TTPBHA](#) is not implemented.

HWU059, bit [11]

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[59] of the stage 1 translation table block or level 3 entry for pages pointed to by [TTBR0](#) if TTBCR2.HPD0==1 and [TTBCR.T2E](#)==1.

Defined values are:

- 0 The stage 1 translation table entry block or level 3 bit cannot be interpreted by hardware for an IMPLEMENTATION DEFINED purpose.
- 1 The stage 1 translation table entry block or level 3 bit can be interpreted by hardware for an IMPLEMENTATION DEFINED purpose if the TTBCR2.HPD0 value is 1.

This bit is RES0 if [ARMv8.2-TTPBHA](#) is not implemented.

HPD1, bit [10]

Hierarchical Permission Disables. This affects the hierarchical control bits, APTable, XNTable, and PXNTable, in the translation tables pointed to by [TTBR1](#).

Defined values are:

- 0 Hierarchical permissions are enabled.
- 1 Hierarchical permissions are disabled if [TTBCR.T2E](#) == 1.

When disabled, the permissions are treated as if the bits are 0.

If [TTBCR.T2E](#) == 0, the hierarchical permissions are enabled.

This bit is RES0 if [ARMv8.2-AA32HPD](#) is not implemented.

HPD0, bit [9]

Hierarchical Permission Disables. This affects the hierarchical control bits, APTable, XNTable, and PXNTable, in the translation tables pointed to by [TTBR0](#).

Defined values are:

- 0 Hierarchical permissions are enabled.
- 1 Hierarchical permissions are disabled if [TTBCR.T2E](#) == 1.

When disabled, the permissions are treated as if the bits are 0.

If [TTBCR.T2E](#) == 0, the hierarchical permissions are enabled.

This bit is RES0 if [ARMv8.2-AA32HPD](#) is not implemented.

Bits [8:0]

Reserved, RES0.

Accessing the TTBCR2

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c2, c0, 3	000	011	0010	1111	0000

Accessibility

The register is accessible in software as follows:

Configuration	Control			Accessibility				Instance
	E2H	TGE	NS	EL0	EL1	EL2	EL3	
EL3 is using AArch32.	x	0	1	-	RW	RW	RW	TTBCR2_ns
EL3 is using AArch32.	x	1	1	-	n/a	RW	RW	TTBCR2_ns
EL3 is not implemented.	x	x	0	-	RW	n/a	n/a	TTBCR2
EL3 is not implemented.	x	0	1	-	RW	RW	n/a	TTBCR2
EL3 is not implemented.	x	1	1	-	n/a	RW	n/a	TTBCR2
EL3 is using AArch64.	x	x	0	-	RW	n/a	n/a	TTBCR2
EL3 is using AArch64.	x	0	1	-	RW	RW	n/a	TTBCR2
EL3 is using AArch64.	x	1	1	-	n/a	RW	n/a	TTBCR2
EL3 is using AArch32.	x	x	0	-	n/a	n/a	RW	TTBCR2_s

When EL3 is using AArch32, write access to TTBCR2_s is UNDEFINED when the CP15SDISABLE signal is asserted HIGH.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If HCR_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
 - If HCR_EL2.TRVM==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If HSTR_EL2.T2==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If HCR_EL2.TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.

- If `HCR_EL2.TRVM==1`, Non-secure read accesses to this register from EL1 are trapped to EL2.
- If `HSTR_EL2.T2==1`, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and `SCR_EL3.NS == 1`:
 - If `HCR.TVM==1`, Non-secure write accesses to this register from EL1 are trapped to Hyp mode.
 - If `HCR.TRVM==1`, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
 - If `HSTR.T2==1`, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

G6.2.158 TTBR0, Translation Table Base Register 0

The TTBR0 characteristics are:

Purpose

Holds the base address of the translation table for the initial lookup for stage 1 of the translation of an address from the lower VA range in the PL1&0 translation regime, and other information for this translation regime.

Configurations

AArch32 System register TTBR0 is architecturally mapped to AArch64 System register [TTBR0_EL1](#).

[TTBCR.EAE](#) determines which TTBR0 format is used:

EAE==0 32-bit format is used. TTBR0[63:32] are ignored.

EAE==1 64-bit format is used.

When EL3 is using AArch32, write access to TTBR0(S) is disabled when the CP15SSDISABLE signal is asserted HIGH.

Used in conjunction with the [TTBCR](#). When the 64-bit TTBR0 format is used, cacheability and shareability information is held in the [TTBCR](#), not in TTBR0.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

TTBR0 is a 64-bit register that can also be accessed as a 32-bit value. If it is accessed as a 32-bit register, accesses read and write bits [31:0] and do not modify bits [63:32].

Field descriptions

The TTBR0 bit assignments are:

When [TTBCR.EAE](#)==0:

TTBR0, bits [31:7]

Translation table base address, bits[31:x], where x is 14-([TTBCR.N](#)). Register bits [x-1:7] are RES0, with the additional requirement that if these bits are not all zero, this is a misaligned translation table base address, with effects that are CONstrained UNPREDICTABLE, and must be one of the following:

- Register bits [x-1:7] are treated as if all the bits are zero. The value read back from these bits is either the value written or zero.
- The result of the calculation of an address for a translation table walk using this register can be corrupted in those bits that are nonzero.

IRGN[0], bit [6]

See the [IRGN\[1\]](#) description.

NOS, bit [5]

Not Outer Shareable. When the value of TTBR0.S is 1, indicates whether the memory associated with a translation table walk is Inner Shareable or Outer Shareable:

- 0 Memory is Outer Shareable.
- 1 Memory is Inner Shareable.

This bit is ignored when the value of TTBR0.S is 0.

RGN, bits [4:3]

Region bits. Indicates the Outer cacheability attributes for the memory associated with the translation table walks:

- 00 Normal memory, Outer Non-cacheable.
- 01 Normal memory, Outer Write-Back Write-Allocate Cacheable.
- 10 Normal memory, Outer Write-Through Cacheable.
- 11 Normal memory, Outer Write-Back no Write-Allocate Cacheable.

IMP, bit [2]

The effect of this bit is IMPLEMENTATION DEFINED. If the translation table implementation does not include any IMPLEMENTATION DEFINED features this bit is UNK/SBZP.

S, bit [1]

Shareable. Indicates whether the memory associated with the translation table walks is Non-shareable:

- 0 Memory is Non-shareable.
- 1 Memory is shareable. The TTBR0.NOS field indicates whether the memory is Inner Shareable or Outer Shareable.

IRGN[1], bit [0]

Inner region bits. IRGN[1:0] indicate the Inner Cacheability attributes for the memory associated with the translation table walks. The possible values of IRGN[1:0] are:

- 00 Normal memory, Inner Non-cacheable.
- 01 Normal memory, Inner Write-Back Write-Allocate Cacheable.
- 10 Normal memory, Inner Write-Through Cacheable.
- 11 Normal memory, Inner Write-Back no Write-Allocate Cacheable.

Note

The encoding of the IRGN bits is counter-intuitive, with register bit[6] being IRGN[0] and register bit[0] being IRGN[1]. This encoding is chosen to give a consistent encoding of memory region types and to ensure that software written for ARMv7 without the Multiprocessing Extensions can run unmodified on an implementation that includes the functionality introduced by the ARMv7 Multiprocessing Extensions.

When TTBCR.EAE==1:

Bits [63:56]

Reserved, RES0.

ASID, bits [55:48]

An ASID for the translation table base address. The [TTBCR.A1](#) field selects either [TTBR0.ASID](#) or [TTBR1.ASID](#).

BADDR, bits [47:1]

Translation table base address, bits[47:x], Bits [x-1:1] are RES0, with the additional requirement that if bits[x-1:3] are not all zero, this is a misaligned translation table base address, with effects that are *CONSTRAINED UNPREDICTABLE*, and must be one of the following:

- Register bits [x-1:3] are treated as if all the bits are zero. The value read back from these bits is either the value written or zero.
- The result of the calculation of an address for a translation table walk using this register can be corrupted in those bits that are nonzero.

x is determined from the value of [TTBCR.TOSZ](#) as follows:

- If [TTBCR.TOSZ](#) is 0 or 1, $x = 5 - \text{TTBCR.TOSZ}$.
- If [TTBCR.TOSZ](#) is greater than 1, $x = 14 - \text{TTBCR.TOSZ}$.

If bits[47:40] of the translation table base address are not zero, an Address size fault is generated.

CnP, bit [0]

In ARMv8.2

Common not Private. In an implementation that includes [ARMv8.2-TTCNP](#), when [TTBCR.EAE](#) ==1, indicates whether each entry that is pointed to by [TTBR0](#) is a member of a common set that can be used by every PE in the Inner Shareable domain for which the value of [TTBR0.CnP](#) is 1.

0 The translation table entries pointed to by this instance of [TTBR0](#), for the current ASID, are permitted to differ from corresponding entries for this instance of [TTBR0](#) for other PEs in the Inner Shareable domain. This is not affected by:

- The value of [TTBR0.CnP](#) on those other PEs.
- The value of [TTBCR.EAE](#) on those other PEs.
- The value of the current ASID or, for the Non-secure instance of [TTBR0](#), the value of the current VMID.

1 The translation table entries pointed to by this instance of [TTBR0](#) are the same as the translation table entries for every other PE in the Inner Shareable domain for which the value of [TTBR0.CnP](#) is 1 for this instance of [TTBR0](#) and all of the following apply:

- The translation table entries are pointed to by this instance of [TTBR0](#).
- The value of the applicable [TTBCR.EAE](#) field is 1.
- The ASID is the same as the current ASID.
- For the Non-secure instance of [TTBR0](#), the VMID is the same as the current VMID.

When a TLB combines entries from stage 1 translation and stage 2 translation into a single entry, that entry can only be shared between different PEs if the value of the CnP bit is 1 for both stage 1 and stage 2.

———— Note ————

If the value of the [TTBR0.CnP](#) bit is 1 on multiple PEs in the same Inner Shareable domain and those [TTBR0](#)s do not point to the same translation table entries when the other conditions specified for the case when the value of CnP is 1 apply, then the results of translations are *CONSTRAINED UNPREDICTABLE*, see [CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values on page K1-6101](#).

In an implementation that does not include [ARMv8.2-TTCNP](#) this field is RES0.

In ARMv8.1 and ARMv8.0.

Reserved, RES0.

Accessing the TTBR0

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c2, c0, 0	000	000	0010	1111	0000

This register can be read using MRRC with the following syntax:

MRRC <syntax>

This register can be written using MCRR with the following syntax:

MCRR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	coproc	CRm
p15, 0, <Rt>, <Rt2>, c2	0000	1111	0010

Accessibility

The register is accessible in software as follows:

Configuration	Control			Accessibility				Instance
	E2H	TGE	NS	EL0	EL1	EL2	EL3	
EL3 is not implemented.	x	x	0	-	RW	n/a	n/a	TTBR0
EL3 is not implemented.	x	0	1	-	RW	RW	n/a	TTBR0
EL3 is not implemented.	x	1	1	-	n/a	RW	n/a	TTBR0
EL3 is using AArch64.	x	x	0	-	RW	n/a	n/a	TTBR0
EL3 is using AArch64.	x	0	1	-	RW	RW	n/a	TTBR0
EL3 is using AArch64.	x	1	1	-	n/a	RW	n/a	TTBR0
EL3 is using AArch32.	x	x	0	-	n/a	n/a	RW	TTBR0_s
EL3 is using AArch32.	x	0	1	-	RW	RW	RW	TTBR0_ns
EL3 is using AArch32.	x	1	1	-	n/a	RW	RW	TTBR0_ns

When EL3 is using AArch32, write access to TTBR0_s is UNDEFINED when the CP15SSDISABLE signal is asserted HIGH.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 0)$:
 - If $HCR_EL2.TVM == 1$, Non-secure write accesses to this register from EL1 are trapped to EL2.
 - If $HCR_EL2.TRVM == 1$, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If $HSTR_EL2.T2 == 1$, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 1) \ \&\& \ (HCR_EL2.TGE == 0)$:
 - If $HCR_EL2.TVM == 1$, Non-secure write accesses to this register from EL1 are trapped to EL2.
 - If $HCR_EL2.TRVM == 1$, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If $HSTR_EL2.T2 == 1$, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $HCR.TVM == 1$, Non-secure write accesses to this register from EL1 are trapped to Hyp mode.
 - If $HCR.TRVM == 1$, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
 - If $HSTR.T2 == 1$, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

G6.2.159 TTBR1, Translation Table Base Register 1

The TTBR1 characteristics are:

Purpose

Holds the base address of the translation table for the initial lookup for stage 1 of the translation of an address from the higher VA range in the PL1&0 translation regime, and other information for this translation regime.

Configurations

AArch32 System register TTBR1 is architecturally mapped to AArch64 System register [TTBR1_EL1](#).

[TTBCR.EAE](#) determines which TTBR1 format is used:

EAE==0 32-bit format is used. TTBR1[63:32] are ignored.

EAE==1 64-bit format is used.

Used in conjunction with the [TTBCR](#). When the 64-bit TTBR1 format is used, cacheability and shareability information is held in the [TTBCR](#), not in TTBR1.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

TTBR1 is a 64-bit register that can also be accessed as a 32-bit value. If it is accessed as a 32-bit register, accesses read and write bits [31:0] and do not modify bits [63:32].

Field descriptions

The TTBR1 bit assignments are:

When [TTBCR.EAE](#)==0:

TTB1, bits [31:7]

Translation table base address, bits[31:14]. Register bits [13:7] are RES0, with the additional requirement that if these bits are not all zero, this is a misaligned translation table base address, with effects that are CONstrained UNPREDICTABLE, and must be one of the following:

- Register bits [13:7] are treated as if all the bits are zero. The value read back from these bits is either the value written or zero.
- The result of the calculation of an address for a translation table walk using this register can be corrupted in those bits that are nonzero.

IRGN[0], bit [6]

See the [IRGN\[1\]](#) description.

NOS, bit [5]

Not Outer Shareable. When the value of TTBR1.S is 1, indicates whether the memory associated with a translation table walk is Inner Shareable or Outer Shareable:

- 0 Memory is Outer Shareable.
- 1 Memory is Inner Shareable.

This bit is ignored when the value of TTBR1.S is 0.

RGN, bits [4:3]

Region bits. Indicates the Outer cacheability attributes for the memory associated with the translation table walks:

- 00 Normal memory, Outer Non-cacheable.
- 01 Normal memory, Outer Write-Back Write-Allocate Cacheable.
- 10 Normal memory, Outer Write-Through Cacheable.
- 11 Normal memory, Outer Write-Back no Write-Allocate Cacheable.

IMP, bit [2]

The effect of this bit is IMPLEMENTATION DEFINED. If the translation table implementation does not include any IMPLEMENTATION DEFINED features this bit is UNK/SBZP.

S, bit [1]

Shareable. Indicates whether the memory associated with the translation table walks is Non-shareable:

- 0 Memory is Non-shareable.
- 1 Memory is shareable. The TTBR1.NOS field indicates whether the memory is Inner Shareable or Outer Shareable.

IRGN[1], bit [0]

Inner region bits. IRGN[1:0] indicate the Inner Cacheability attributes for the memory associated with the translation table walks. The possible values of IRGN[1:0] are:

- 00 Normal memory, Inner Non-cacheable.
- 01 Normal memory, Inner Write-Back Write-Allocate Cacheable.
- 10 Normal memory, Inner Write-Through Cacheable.
- 11 Normal memory, Inner Write-Back no Write-Allocate Cacheable.

Note

The encoding of the IRGN bits is counter-intuitive, with register bit[6] being IRGN[0] and register bit[0] being IRGN[1]. This encoding is chosen to give a consistent encoding of memory region types and to ensure that software written for ARMv7 without the Multiprocessing Extensions can run unmodified on an implementation that includes the functionality introduced by the ARMv7 Multiprocessing Extensions.

When TTBCR.EAE==1:

Bits [63:56]

Reserved, RES0.

ASID, bits [55:48]

An ASID for the translation table base address. The [TTBCR.A1](#) field selects either [TTBR0.ASID](#) or [TTBR1.ASID](#).

BADDR, bits [47:1]

Translation table base address, bits[47:x], Bits [x-1:1] are RES0, with the additional requirement that if bits[x-1:3] are not all zero, this is a misaligned translation table base address, with effects that are *CONSTRAINED UNPREDICTABLE*, and must be one of the following:

- Register bits [x-1:3] are treated as if all the bits are zero. The value read back from these bits is either the value written or zero.
- The result of the calculation of an address for a translation table walk using this register can be corrupted in those bits that are nonzero.

x is determined from the value of [TTBCR.T1SZ](#) as follows:

- If [TTBCR.T1SZ](#) is 0 or 1, $x = 5 - \text{TTBCR.T1SZ}$.
- If [TTBCR.T1SZ](#) is greater than 1, $x = 14 - \text{TTBCR.T1SZ}$.

If bits[47:40] of the translation table base address are not zero, an Address size fault is generated.

CnP, bit [0]

In ARMv8.2

Common not Private. In an implementation that includes [ARMv8.2-TTCNP](#), when [TTBCR.EAE](#) ==1, indicates whether each entry that is pointed to by [TTBR1](#) is a member of a common set that can be used by every PE in the Inner Shareable domain for which the value of [TTBR1.CnP](#) is 1.

0 The translation table entries pointed to by this instance of [TTBR1](#), for the current ASID, are permitted to differ from corresponding entries for this instance of [TTBR1](#) for other PEs in the Inner Shareable domain. This is not affected by:

- The value of [TTBR1.CnP](#) on those other PEs.
- The value of [TTBCR.EAE](#) on those other PEs.
- The value of the current ASID or, for the Non-secure instance of [TTBR1](#), the value of the current VMID.

1 The translation table entries pointed to by this instance of [TTBR1](#) are the same as the translation table entries for every other PE in the Inner Shareable domain for which the value of [TTBR1.CnP](#) is 1 for this instance of [TTBR1](#) and all of the following apply:

- The translation table entries are pointed to by this instance of [TTBR1](#).
- The value of the applicable [TTBCR.EAE](#) field is 1.
- The ASID is the same as the current ASID.
- For the Non-secure instance of [TTBR1](#), the VMID is the same as the current VMID.

When a TLB combines entries from stage 1 translation and stage 2 translation into a single entry, that entry can only be shared between different PEs if the value of the CnP bit is 1 for both stage 1 and stage 2.

———— **Note** ————

If the value of the [TTBR1.CnP](#) bit is 1 on multiple PEs in the same Inner Shareable domain and those [TTBR1](#)s do not point to the same translation table entries when the other conditions specified for the case when the value of CnP is 1 apply, then the results of translations are *CONSTRAINED UNPREDICTABLE*, see *CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values on page K1-6101*.

In an implementation that does not include [ARMv8.2-TTCNP](#) this field is RES0.

In ARMv8.1 and ARMv8.0.

Reserved, RES0.

Accessing the TTBR1

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c2, c0, 1	000	001	0010	1111	0000

This register can be read using MRRC with the following syntax:

MRRC <syntax>

This register can be written using MCRR with the following syntax:

MCRR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	coproc	CRm
p15, 1, <Rt>, <Rt2>, c2	0001	1111	0010

Accessibility

The register is accessible in software as follows:

Configuration	Control			Accessibility				Instance
	E2H	TGE	NS	EL0	EL1	EL2	EL3	
EL3 is not implemented.	x	x	0	-	RW	n/a	n/a	TTBR1
EL3 is not implemented.	x	0	1	-	RW	RW	n/a	TTBR1
EL3 is not implemented.	x	1	1	-	n/a	RW	n/a	TTBR1
EL3 is using AArch64.	x	x	0	-	RW	n/a	n/a	TTBR1
EL3 is using AArch64.	x	0	1	-	RW	RW	n/a	TTBR1
EL3 is using AArch64.	x	1	1	-	n/a	RW	n/a	TTBR1
EL3 is using AArch32.	x	0	1	-	RW	RW	RW	TTBR1_ns
EL3 is using AArch32.	x	1	1	-	n/a	RW	RW	TTBR1_ns
EL3 is using AArch32.	x	x	0	-	n/a	n/a	RW	TTBR1_s

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \&\& (HCR_EL2.E2H == 0)$:
 - If $HCR_EL2.TVM == 1$, Non-secure write accesses to this register from EL1 are trapped to EL2.
 - If $HCR_EL2.TRVM == 1$, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If $HSTR_EL2.T2 == 1$, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \&\& (HCR_EL2.E2H == 1) \&\& (HCR_EL2.TGE == 0)$:
 - If $HCR_EL2.TVM == 1$, Non-secure write accesses to this register from EL1 are trapped to EL2.
 - If $HCR_EL2.TRVM == 1$, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If $HSTR_EL2.T2 == 1$, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $HCR.TVM == 1$, Non-secure write accesses to this register from EL1 are trapped to Hyp mode.
 - If $HCR.TRVM == 1$, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
 - If $HSTR.T2 == 1$, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

G6.2.160 VBAR, Vector Base Address Register

The VBAR characteristics are:

Purpose

When high exception vectors are not selected, holds the vector base address for exceptions that are not taken to Monitor mode or to Hyp mode.

Software must program VBAR(NS) with the required initial value as part of the PE boot sequence.

Configurations

AArch32 System register VBAR is architecturally mapped to AArch64 System register [VBAR_EL1](#)[31:0].

When EL3 is using AArch32, write access to VBAR(S) is disabled when the CP15SDISABLE signal is asserted HIGH.

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into an Exception level that is using AArch32. If the PE resets into EL3 using AArch32 they apply only to the Secure instance of the register. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

Attributes

VBAR is a 32-bit register.

Field descriptions

The VBAR bit assignments are:

Bits [31:5]

Vector Base Address. Bits[31:5] of the base address of the exception vectors for exceptions taken to this Exception level. Bits[4:0] of an exception vector are the exception offset.

When this register has an architecturally-defined reset value, this field resets to an IMPLEMENTATION DEFINED value.

Bits [4:0]

Reserved, RES0.

Accessing the VBAR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c12, c0, 0	000	000	1100	1111	0000

Accessibility

The register is accessible in software as follows:

Configuration	Control			Accessibility				Instance
	E2H	TGE	NS	EL0	EL1	EL2	EL3	
EL3 is using AArch32.	x	x	0	-	n/a	n/a	RW	VBAR_s
EL3 is using AArch32.	x	0	1	-	RW	RW	RW	VBAR_ns
EL3 is using AArch32.	x	1	1	-	n/a	RW	RW	VBAR_ns
EL3 is not implemented.	x	x	0	-	RW	n/a	n/a	VBAR
EL3 is not implemented.	x	0	1	-	RW	RW	n/a	VBAR
EL3 is not implemented.	x	1	1	-	n/a	RW	n/a	VBAR
EL3 is using AArch64.	x	x	0	-	RW	n/a	n/a	VBAR
EL3 is using AArch64.	x	0	1	-	RW	RW	n/a	VBAR
EL3 is using AArch64.	x	1	1	-	n/a	RW	n/a	VBAR

When EL3 is using AArch32, write access to VBAR_s is UNDEFINED when the CP15SDISABLE signal is asserted HIGH.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If HSTR_EL2.T12==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If HSTR_EL2.T12==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HSTR.T12==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

G6.2.161 VMPIDR, Virtualization Multiprocessor ID Register

The VMPIDR characteristics are:

Purpose

Holds the value of the Virtualization Multiprocessor ID. This is the value returned by Non-secure EL1 reads of [MPIDR](#).

Configurations

AArch32 System register VMPIDR is architecturally mapped to AArch64 System register [VMPIDR_EL2](#)[31:0].

If EL2 is not implemented but EL3 is implemented, this register takes the value of the [MPIDR](#).

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into EL2 with EL2 using AArch32, or into EL3 with EL3 using AArch32. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

Attributes

VMPIDR is a 32-bit register.

Field descriptions

The VMPIDR bit assignments are:

M, bit [31]

Indicates whether this implementation includes the functionality introduced by the ARMv7 Multiprocessing Extensions. The possible values of this bit are:

- 0 This implementation does not include the ARMv7 Multiprocessing Extensions functionality.
 - 1 This implementation includes the ARMv7 Multiprocessing Extensions functionality.
- In ARMv8 this bit is RES1.

U, bit [30]

Indicates a Uniprocessor system, as distinct from PE 0 in a multiprocessor system. The possible values of this bit are:

- 0 Processor is part of a multiprocessor system.
- 1 Processor is part of a uniprocessor system.

When this register has an architecturally-defined reset value, this field resets to the value of [MPIDR.U](#).

Bits [29:25]

Reserved, RES0.

MT, bit [24]

Indicates whether the lowest level of affinity consists of logical PEs that are implemented using a multithreading type approach. The possible values of this bit are:

- 0 Performance of PEs at the lowest affinity level is largely independent.
- 1 Performance of PEs at the lowest affinity level is very interdependent.

When this register has an architecturally-defined reset value, this field resets to the value of [MPIDR.MT](#).

Aff2, bits [23:16]

Affinity level 2. The least significant affinity level field, for this PE in the system.

When this register has an architecturally-defined reset value, this field resets to the value of [MPIDR.Aff2](#).

Aff1, bits [15:8]

Affinity level 1. The intermediate affinity level field, for this PE in the system.

When this register has an architecturally-defined reset value, this field resets to the value of [MPIDR.Aff1](#).

Aff0, bits [7:0]

Affinity level 0. The most significant affinity level field, for this PE in the system.

When this register has an architecturally-defined reset value, this field resets to the value of [MPIDR.Aff0](#).

Accessing the VMPIDR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 4, <Rt>, c0, c0, 5	100	101	0000	1111	0000

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	-
x	0	1	-	-	RW	RW
x	1	1	-	n/a	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If [HSTR_EL2.T0](#)==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If [HSTR_EL2.T0](#)==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If [HSTR.T0](#)==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

G6.2.162 VPIDR, Virtualization Processor ID Register

The VPIDR characteristics are:

Purpose

Holds the value of the Virtualization Processor ID. This is the value returned by Non-secure EL1 reads of [MIDR](#).

Configurations

AArch32 System register VPIDR is architecturally mapped to AArch64 System register [VPIDR_EL2](#).

If EL2 is not implemented but EL3 is implemented, this register takes the value of the [MIDR](#).

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into EL2 with EL2 using AArch32, or into EL3 with EL3 using AArch32. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

Attributes

VPIDR is a 32-bit register.

Field descriptions

The VPIDR bit assignments are:

Implementer, bits [31:24]

The Implementer code. This field must hold an implementer code that has been assigned by ARM. Assigned codes include the following:

Hex representation	ASCII representation	Implementer
0x41	A	ARM Limited
0x42	B	Broadcom Corporation
0x43	C	Cavium Inc.
0x44	D	Digital Equipment Corporation
0x49	I	Infineon Technologies AG
0x4D	M	Motorola or Freescale Semiconductor Inc.
0x4E	N	NVIDIA Corporation
0x50	P	Applied Micro Circuits Corporation
0x51	Q	Qualcomm Inc.
0x56	V	Marvell International Ltd.
0x69	i	Intel Corporation

ARM can assign codes that are not published in this manual. All values not assigned by ARM are reserved and must not be used.

When this register has an architecturally-defined reset value, this field resets to the value of [MIDR.Implementer](#).

Variant, bits [23:20]

An IMPLEMENTATION DEFINED variant number. Typically, this field is used to distinguish between different product variants, or major revisions of a product.

When this register has an architecturally-defined reset value, this field resets to the value of [MIDR.Variant](#).

Architecture, bits [19:16]

The permitted values of this field are:

- 0001 ARMv4
- 0010 ARMv4T
- 0011 ARMv5 (obsolete)
- 0100 ARMv5T
- 0101 ARMv5TE
- 0110 ARMv5TEJ
- 0111 ARMv6
- 1111 Architectural features are individually identified in the ID_* registers, see [Identification registers, functional group on page G4-4727](#).

All other values are reserved.

When this register has an architecturally-defined reset value, this field resets to the value of [MIDR.Architecture](#).

PartNum, bits [15:4]

An IMPLEMENTATION DEFINED primary part number for the device.

On processors implemented by ARM, if the top four bits of the primary part number are 0x0 or 0x7, the variant and architecture are encoded differently.

When this register has an architecturally-defined reset value, this field resets to the value of [MIDR.PartNum](#).

Revision, bits [3:0]

An IMPLEMENTATION DEFINED revision number for the device.

When this register has an architecturally-defined reset value, this field resets to the value of [MIDR.Revision](#).

Accessing the VPIDR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 4, <Rt>, c0, c0, 0	100	000	0000	1111	0000

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	-
x	0	1	-	-	RW	RW
x	1	1	-	n/a	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 0)$:
 - If $HSTR_EL2.T0 == 1$, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 1) \ \&\& \ (HCR_EL2.TGE == 0)$:
 - If $HSTR_EL2.T0 == 1$, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $HSTR.T0 == 1$, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

G6.2.163 VTCR, Virtualization Translation Control Register

The VTCR characteristics are:

Purpose

The control register for stage 2 of the Non-secure PL1&0 translation regime.

Note

This stage of translation always uses the Long-descriptor translation table format.

Configurations

AArch32 System register VTCR is architecturally mapped to AArch64 System register [VTCR_EL2](#).

If EL2 is not implemented, this register is RES0 from EL3.

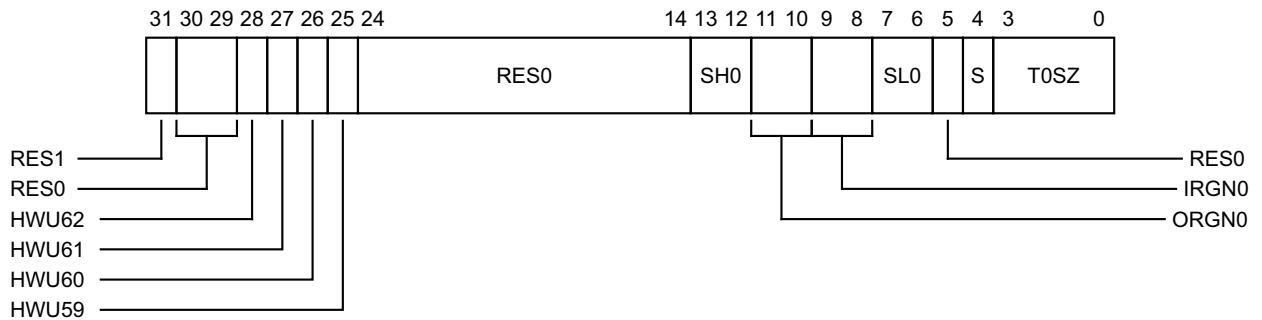

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

VTCR is a 32-bit register.

Field descriptions

The VTCR bit assignments are:

Bit [31]

Reserved, RES1.

Bits [30:29]

Reserved, RES0.

HWU62, bit [28]

In ARMv8.2

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[62] of the stage 2 translation table block or level 3 entry.

Defined values are:

- 0 The stage 2 translation table entry block or level 3 entry cannot be interpreted by hardware for an IMPLEMENTATION DEFINED purpose.
- 1 The stage 2 translation table entry block or level 3 entry can be interpreted by hardware for an IMPLEMENTATION DEFINED purpose.

This bit is RES0 if [ARMv8.2-TTPBHA](#) is not implemented.

In ARMv8.1 and ARMv8.0.

Reserved, RES0.

HWU61, bit [27]

In ARMv8.2

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[61] of the stage 2 translation table block or level 3 entry.

Defined values are:

- 0 The stage 2 translation table entry block or level 3 entry cannot be interpreted by hardware for an IMPLEMENTATION DEFINED purpose.
- 1 The stage 2 translation table entry block or level 3 entry can be interpreted by hardware for an IMPLEMENTATION DEFINED purpose.

This bit is RES0 if [ARMv8.2-TTPBHA](#) is not implemented.

In ARMv8.1 and ARMv8.0.

Reserved, RES0.

HWU60, bit [26]

In ARMv8.2

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[60] of the stage 2 translation table block or level 3 entry.

Defined values are:

- 0 The stage 2 translation table entry block or level 3 entry cannot be interpreted by hardware for an IMPLEMENTATION DEFINED purpose.
- 1 The stage 2 translation table entry block or level 3 entry can be interpreted by hardware for an IMPLEMENTATION DEFINED purpose.

This bit is RES0 if [ARMv8.2-TTPBHA](#) is not implemented.

In ARMv8.1 and ARMv8.0.

Reserved, RES0.

HWU59, bit [25]

In ARMv8.2

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[59] of the stage 2 translation table block or level 3 entry.

Defined values are:

- 0 The stage 2 translation table entry block or level 3 entry cannot be interpreted by hardware for an IMPLEMENTATION DEFINED purpose.
- 1 The stage 2 translation table entry block or level 3 entry can be interpreted by hardware for an IMPLEMENTATION DEFINED purpose.

This bit is RES0 if [ARMv8.2-TTPBHA](#) is not implemented.

In ARMv8.1 and ARMv8.0.

Reserved, RES0.

Bits [24:14]

Reserved, RES0.

SH0, bits [13:12]

Shareability attribute for memory associated with translation table walks using [VTTBR](#).

- 00 Non-shareable
- 10 Outer Shareable
- 11 Inner Shareable

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is CONstrained UNPREDICTABLE, as described in [Reserved values in System and memory-mapped registers and translation table entries](#) on page K1-6117.

ORGN0, bits [11:10]

Outer cacheability attribute for memory associated with translation table walks using [VTTBR](#).

00	Normal memory, Outer Non-cacheable
01	Normal memory, Outer Write-Back Read-Allocate Write-Allocate Cacheable
10	Normal memory, Outer Write-Through Read-Allocate No Write-Allocate Cacheable
11	Normal memory, Outer Write-Back Read-Allocate No Write-Allocate Cacheable

IRGN0, bits [9:8]

Inner cacheability attribute for memory associated with translation table walks using [VTTBR](#).

00	Normal memory, Inner Non-cacheable
01	Normal memory, Inner Write-Back Read-Allocate Write-Allocate Cacheable
10	Normal memory, Inner Write-Through Read-Allocate No Write-Allocate Cacheable
11	Normal memory, Inner Write-Back Read-Allocate No Write-Allocate Cacheable

SL0, bits [7:6]

Starting level for translation table walks using [VTTBR](#).

00	Start at level 2
01	Start at level 1

All other values are reserved. If this field is programmed to a reserved value, or to a value that is not consistent with the programming of T0SZ, then a stage 2 level 1 Translation fault is generated.

Bit [5]

Reserved, RES0.

S, bit [4]

Sign extension bit. This bit must be programmed to the value of T0SZ[3]. If it is not, then the behavior is **CONSTRAINED UNPREDICTABLE** and the stage 2 T0SZ value is treated as an UNKNOWN value, see [Misprogramming VTCR.S on page K1-6114](#).

T0SZ, bits [3:0]

The size offset of the memory region addressed by [VTTBR](#). The region size is $2^{(32-T0SZ)}$ bytes.

This field holds a four-bit signed integer value, meaning it supports values from -8 to 7.

———— Note —————

This is different from the other translation control registers, where TnSZ holds a three-bit unsigned integer, supporting values from 0 to 7.

If this field is programmed to a value that is not consistent with the programming of SL0 then a stage 2 level 1 Translation fault is generated.

Accessing the VTCR

This register can be read using MRC with the following syntax:

```
MRC <syntax>
```

This register can be written using MCR with the following syntax:

```
MCR <syntax>
```

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 4, <Rt>, c2, c1, 2	100	010	0010	1111	0001

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	-
x	0	1	-	-	RW	RW
x	1	1	-	n/a	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If HSTR_EL2.T2==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If HSTR_EL2.T2==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HSTR.T2==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

G6.2.164 VTTBR, Virtualization Translation Table Base Register

The VTTBR characteristics are:

Purpose

Holds the base address of the translation table for the initial lookup for stage 2 of an address translation in the Non-secure PL1&0 translation regime, and other information for this translation regime.

Configurations

AArch32 System register VTTBR is architecturally mapped to AArch64 System register [VTTBR_EL2](#).

If EL2 is not implemented, this register is RES0 from EL3.

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into EL2 with EL2 using AArch32, or into EL3 with EL3 using AArch32. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

Attributes

VTTBR is a 64-bit register.

Field descriptions

The VTTBR bit assignments are:

Bits [63:56]

Reserved, RES0.

VMID, bits [55:48]

The VMID for the translation table.

When this register has an architecturally-defined reset value, this field resets to 0.

BADDR, bits [47:1]

Translation table base address, bits[47:x], Bits [x-1:1] are RES0, with the additional requirement that if bits[x-1:3] are not all zero, this is a misaligned translation table base address, with effects that are CONstrained UNPREDICTABLE, and must be one of the following:

- Register bits [x-1:3] are treated as if all the bits are zero. The value read back from these bits is either the value written or zero.
- The result of the calculation of an address for a translation table walk using this register can be corrupted in those bits that are nonzero.

x is determined from the value of [VTCR.SL0](#) and [VTCR.T0SZ](#) as follows:

- If [VTCR.SL0](#) is 00, meaning that lookup starts at level 2, then x is 14 - [VTCR.T0SZ](#).
- If [VTCR.SL0](#) is 01, meaning that lookup starts at level 1, then x is 5 - [VTCR.T0SZ](#).
- If [VTCR.SL0](#) is either 10 or 11 then a stage 2 level 1 Translation fault is generated.

If bits[47:40] of the translation table base address are not zero, an Address size fault is generated.

This field resets to a value that is architecturally UNKNOWN.

CnP, bit [0]

In ARMv8.2

Common not Private. In an implementation that includes [ARMv8.2-TTCNP](#), indicates whether each entry that is pointed to by VTTBR is a member of a common set that can be used by every PE in the Inner Shareable domain for which the value of VTTBR.CnP is 1.

- 0 The translation table entries pointed to by VTTBR are permitted to differ from the entries for VTTBR for other PEs in the Inner Shareable domain. This is not affected by the value of the current VMID.
- 1 The translation table entries pointed to by VTTBR are the same as the translation table entries for every other PE in the Inner Shareable domain for which the value of VTTBR.CnP is 1 and the VMID is the same as the current VMID.

When a TLB combines entries from stage 1 translation and stage 2 translation into a single entry, that entry can only be shared between different PEs if the value of the CnP bit is 1 for both stage 1 and stage 2.

Note

If the value of the VTTBR.CnP bit is 1 on multiple PEs in the same Inner Shareable domain and those VTTBRs do not point to the same translation table entries when the VMID value is the same as the current VMID, then the results of translations are *CONSTRAINED UNPREDICTABLE*, see [CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values on page K1-6101](#).

In an implementation that does not include [ARMv8.2-TTCNP](#) this field is RES0.

In ARMv8.1 and ARMv8.0.

Reserved, RES0.

Accessing the VTTBR

This register can be read using MRRC with the following syntax:

MRRC <syntax>

This register can be written using MCRR with the following syntax:

MCRR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	coproc	CRm
p15, 6, <Rt>, <Rt2>, c2	0110	1111	0010

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	-
x	0	1	-	-	RW	RW
x	1	1	-	n/a	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 0)$:
 - If $HSTR_EL2.T2 == 1$, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 1) \ \&\& \ (HCR_EL2.TGE == 0)$:
 - If $HSTR_EL2.T2 == 1$, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $HSTR.T2 == 1$, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

G6.3 Debug registers

This section lists the Debug System registers in AArch32 state, in alphabetic order.

G6.3.1 DBGAUTHSTATUS, Debug Authentication Status register

The DBGAUTHSTATUS characteristics are:

Purpose

Provides information about the state of the IMPLEMENTATION DEFINED authentication interface for debug.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register DBGAUTHSTATUS is architecturally mapped to AArch64 System register [DBGAUTHSTATUS_EL1](#).

AArch32 System register DBGAUTHSTATUS is architecturally mapped to External register [DBGAUTHSTATUS_EL1](#).

This register is required in all implementations.

Attributes

DBGAUTHSTATUS is a 32-bit register.

Field descriptions

The DBGAUTHSTATUS bit assignments are:

Bits [31:8]

Reserved, RES0.

SNID, bits [7:6]

Secure non-invasive debug. Possible values of this field are:

- 00 Not implemented. EL3 is not implemented and the implemented Security state is Non-secure state.
- 10 Implemented and disabled. ExternalSecureNoninvasiveDebugEnabled() == FALSE.
- 11 Implemented and enabled. ExternalSecureNoninvasiveDebugEnabled() == TRUE.

Other values are reserved.

SID, bits [5:4]

Secure invasive debug. Possible values of this field are:

- 00 Not implemented. EL3 is not implemented and the implemented Security state is Non-secure state.
- 10 Implemented and disabled. ExternalSecureInvasiveDebugEnabled() == FALSE.
- 11 Implemented and enabled. ExternalSecureInvasiveDebugEnabled() == TRUE.

Other values are reserved.

NSNID, bits [3:2]

Non-secure non-invasive debug. Possible values of this field are:

- 00 Not implemented. EL3 is not implemented and the implemented Security state is Secure state.

- 10 Implemented and disabled. ExternalNoninvasiveDebugEnabled() == FALSE.
 - 11 Implemented and enabled. ExternalNoninvasiveDebugEnabled() == TRUE.
- Other values are reserved.

NSID, bits [1:0]

Non-secure invasive debug. Possible values of this field are:

- 00 Not implemented. EL3 is not implemented and the implemented Security state is Secure state.
 - 10 Implemented and disabled. ExternalInvasiveDebugEnabled() == FALSE.
 - 11 Implemented and enabled. ExternalInvasiveDebugEnabled() == TRUE.
- Other values are reserved.

Accessing the DBGAUTHSTATUS

This register can be read using MRC with the following syntax:

MRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p14, 0, <Rt>, c7, c14, 6	000	110	0111	1110	1110

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	RO	n/a	RO
x	0	1	-	RO	RO	RO
x	1	1	-	n/a	RO	RO

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and SCR_EL3.NS == 1:
 - If MDCR_EL2.TDA==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HDCR.TDA==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
- When EL3 is implemented and is using AArch64:
 - If MDCR_EL3.TDA==1, read accesses to this register from EL1 and EL2 are trapped to EL3.

G6.3.2 DBGBCR<n>, Debug Breakpoint Control Registers, n = 0 - 15

The DBGBCR<n> characteristics are:

Purpose

Holds control information for a breakpoint. Forms breakpoint n together with value register [DBGBVR<n>](#). If EL2 is implemented and this breakpoint supports Context matching, [DBGBVR<n>](#) can be associated with a Breakpoint Extended Value Register [DBGBXVR<n>](#) for VMID matching.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register DBGBCR<n> is architecturally mapped to AArch64 System register [DBGBCR<n>_EL1](#).

AArch32 System register DBGBCR<n> is architecturally mapped to External register [DBGBCR<n>_EL1](#).

If breakpoint n is not implemented then this register is unallocated.

This register is in the Cold reset domain. On a Cold reset RW fields in this register reset to architecturally UNKNOWN values. The register is not affected by a Warm reset.

Attributes

DBGBCR<n> is a 32-bit register.

Field descriptions

The DBGBCR<n> bit assignments are:

When the E field is zero, all the other fields in the register are ignored.

Bits [31:24]

Reserved, RES0.

BT, bits [23:20]

Breakpoint Type. Possible values are:

- 0000 Unlinked instruction address match.
- 0001 Linked instruction address match.
- 0010 Unlinked Context ID match.
- 0011 Linked Context ID match.
- 0100 Unlinked instruction address mismatch.
- 0101 Linked instruction address mismatch.
- 0110 Unlinked [CONTEXTIDR_EL1](#) match (introduced in ARMv8.1).
- 0111 Linked [CONTEXTIDR_EL1](#) match (introduced in ARMv8.1).
- 1000 Unlinked VMID match.
- 1001 Linked VMID match.

1010	Unlinked VMID and Context ID match.
1011	Linked VMID and Context ID match.
1100	Unlinked <code>CONTEXTIDR_EL2</code> match (introduced in ARMv8.1).
1101	Linked <code>CONTEXTIDR_EL2</code> match (introduced in ARMv8.1).
1110	Unlinked Full Context ID match (introduced in ARMv8.1).
1111	Linked Full Context ID match (introduced in ARMv8.1).

The field breaks down as follows:

- `BT[3:1]`: Base type.

000	Match address. <code>DBGVVR<n></code> is the address of an instruction.
001	Match Context ID. <code>DBGVVR<n>.ContextID</code> is a Context ID compared against <code>CONTEXTIDR</code> when <code>ARMv8.1-VHE</code> is not implemented, or not in a Host OS or a Host Application. When <code>ARMv8.1-VHE</code> is implemented, and in a Host OS or Host Application, the Context ID is compared against <code>CONTEXTIDR_EL2</code> .
010	Mismatch address. <code>DBGVVR<n></code> is the address of an instruction to be stepped.
011	Match <code>CONTEXTIDR_EL1</code> . <code>DBGVVR<n>.ContextID</code> is a Context ID compared against <code>CONTEXTIDR</code> .
100	Match VMID. <code>DBGXVVR<n>.VMID</code> is a VMID compared against <code>VTTBR.VMID</code> .
101	Match VMID and Context ID. <code>DBGVVR<n>.ContextID</code> is a Context ID compared against <code>CONTEXTIDR</code> , and <code>DBGXVVR<n>.VMID</code> is a VMID compared against <code>VTTBR.VMID</code> .
110	Match <code>CONTEXTIDR_EL2</code> . <code>DBGXVVR<n>.ContextID2</code> is a Context ID compared against <code>CONTEXTIDR_EL2</code> .
111	Match Full Context ID. <code>DBGVVR<n>.ContextID</code> is compared against <code>CONTEXTIDR_EL1</code> , and <code>DBGXVVR<n>.ContextID2</code> is compared against <code>CONTEXTIDR_EL2</code> .
- `BT[0]`: Enable linking.

Constraints on breakpoint programming mean some values are reserved under certain conditions. For more information, see [Reserved `DBGBCR<n>.BT` values on page G2-4490](#).

This field resets to a value that is architecturally UNKNOWN.

LBN, bits [19:16]

Linked breakpoint number. For Linked address matching breakpoints, this specifies the index of the Context-matching breakpoint linked to.

For all other breakpoint types this field is ignored and reads of the register return an UNKNOWN value.

This field is ignored when the value of `DBGBCR<n>.E` is 0.

This field resets to a value that is architecturally UNKNOWN.

SSC, bits [15:14]

Security state control. Determines the Security states under which a Breakpoint debug event for breakpoint `n` is generated. This field must be interpreted along with the HMC and PMC fields, and there are constraints on the permitted values of the {HMC, SSC, PMC} fields. For more information, including the effect of programming the fields to a reserved set of values, see [Breakpoint usage constraints on page G2-4490](#).

For more information on the operation of the SSC, HMC, and PMC fields, see [Execution conditions for which a breakpoint generates Breakpoint exceptions on page G2-4480](#).

This field resets to a value that is architecturally UNKNOWN.

HMC, bit [13]

Higher mode control. Determines the debug perspective for deciding when a Breakpoint debug event for breakpoint n is generated. This field must be interpreted along with the SSC and PMC fields, and there are constraints on the permitted values of the {HMC, SSC, PMC} fields. For more information see the SSC, bits [15:14] description.

For more information on the operation of the SSC, HMC, and PMC fields, see [Execution conditions for which a breakpoint generates Breakpoint exceptions on page G2-4480](#).

This field resets to a value that is architecturally UNKNOWN.

Bits [12:9]

Reserved, RES0.

BAS, bits [8:5]

Byte address select. Defines which half-words an address-matching breakpoint matches, regardless of the instruction set and Execution state.

The permitted values depend on the breakpoint type.

For Address match breakpoints, the permitted values are:

BAS	Match instruction at	Constraint for debuggers
0011	DBGBVR<n>	Use for T32 instructions.
1100	DBGBVR<n>+2	Use for T32 instructions.
1111	DBGBVR<n>	Use for A32 instructions.

All other values are reserved. For more information, see [Reserved DBGBCR<n>.{SSC, HMC, PMC} values on page G2-4491](#).

For more information on using the BAS field in Address Match breakpoints, see [Using the BAS field in Address Match breakpoints on page G2-4483](#).

For Address mismatch breakpoints in an AArch32 stage 1 translation regime, the permitted values are:

BAS	Step instruction at	Constraint for debuggers
0000	-	Use for a match anywhere breakpoint.
0011	DBGBVR<n>	Use for stepping T32 instructions.
1100	DBGBVR<n>+2	Use for stepping T32 instructions.
1111	DBGBVR<n>	Use for stepping A32 instructions.

All other values are reserved. For more information, see [Reserved DBGBCR<n>.{SSC, HMC, PMC} values on page G2-4491](#).

For more information on using the BAS field in address mismatch breakpoints, see [Using the BAS field in Address Match breakpoints on page G2-4483](#).

For Context matching breakpoints, this field is RES1 and ignored.

If this field is implemented as an RW field, it resets to a value that is architecturally UNKNOWN.

Bits [4:3]

Reserved, RES0.

PMC, bits [2:1]

Privilege mode control. Determines the Exception level or levels at which a Breakpoint debug event for breakpoint n is generated. This field must be interpreted along with the SSC and HMC fields, and there are constraints on the permitted values of the {HMC, SSC, PMC} fields. For more information see the DBGBCR<n>.SSC description.

For more information on the operation of the SSC, HMC, and PMC fields, see [Execution conditions for which a breakpoint generates Breakpoint exceptions on page G2-4480](#).

This field resets to a value that is architecturally UNKNOWN.

E, bit [0]

Enable breakpoint DBGBVR<n>. Possible values are:

- 0 Breakpoint disabled.
- 1 Breakpoint enabled.

This field resets to a value that is architecturally UNKNOWN.

Accessing the DBGBCR<n>

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p14, 0, <Rt>, c0, <CRm>, 5	000	101	0000	1110	n<3:0>

- <CRm> is in the range c0 - c15.

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	RW	n/a	RW
x	0	1	-	RW	RW	RW
x	1	1	-	n/a	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see:

- [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state.
- [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state.
- [Software Access debug event on page H3-5493](#) for accesses to this register taken to Debug state.

Subject to the prioritization rules:

- In both security states, and not dependent on other bits:
 - If `EDSCR.TDA==1`, `DBGOSLSR.OSLK==0`, and halting is allowed, accesses to this register from EL1 and EL2 generate a Software Access debug event.
- When EL2 is implemented and is using AArch64 and `SCR_EL3.NS == 1`:
 - If `MDCR_EL2.TDA==1`, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and `SCR_EL3.NS == 1`:
 - If `HDCR.TDA==1`, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
- When EL3 is implemented and is using AArch64:
 - If `MDCR_EL3.TDA==1`, accesses to this register from EL1 and EL2 are trapped to EL3.

G6.3.3 DBGBVR<n>, Debug Breakpoint Value Registers, n = 0 - 15

The DBGBVR<n> characteristics are:

Purpose

Holds a value for use in breakpoint matching, either the virtual address of an instruction or a context ID. Forms breakpoint n together with control register [DBGBCR<n>](#). If EL2 is implemented and this breakpoint supports Context matching, DBGBVR<n> can be associated with a Breakpoint Extended Value Register [DBGXVR<n>](#) for VMID matching.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register DBGBVR<n> is architecturally mapped to AArch64 System register [DBGBVR<n>_EL1](#)[31:0].

AArch32 System register DBGBVR<n> is architecturally mapped to External register [DBGBVR<n>_EL1](#)[31:0].

If breakpoint n is not implemented then this register is unallocated.

This register is in the Cold reset domain. On a Cold reset RW fields in this register reset to architecturally UNKNOWN values. The register is not affected by a Warm reset.

———— Note ————

Writes to DBGBVR<n> do not modify [DBGBVR<n>_EL1](#)[63:32].

Attributes

How this register is interpreted depends on the value of [DBGBCR<n>.BT](#).

- When [DBGBCR<n>.BT](#) is 0b0x0x, this register holds a virtual address.
- When [DBGBCR<n>.BT](#) is 0b001x, 0b101x, or 0b111x, this register holds a Context ID.

For other values of [DBGBCR<n>.BT](#), this register is RES0.

Some breakpoints might not support Context ID comparison. For more information, see the description of the [DBGDIDR.CTX_CMPs](#) field.

Field descriptions

The DBGBVR<n> bit assignments are:

When [DBGBCR<n>.BT==0b0x0x](#):

VA[31:2], bits [31:2]

Bits[31:2] of the address value for comparison.

This field resets to a value that is architecturally UNKNOWN.

Bits [1:0]

Reserved, RES0.

When $DBGBCR<n>.BT==0b001x$:

ContextID, bits [31:0]

Context ID value for comparison.

The value is compared against [CONTEXTIDR](#) in the following cases:

- The PE is in Secure state.
- EL2 is using AArch32.
- When [ARMv8.1-VHE](#) is not implemented.
- When [ARMv8.1-VHE](#) is implemented, EL2 is using AArch64, and [HCR_EL2.E2H](#) is 0.
- When [ARMv8.1-VHE](#) is implemented, EL2 is using AArch64, [HCR_EL2](#).{E2H, TGE} is {1, 0}, and the PE is in Non-secure EL0 or EL1.

When [ARMv8.1-VHE](#) is implemented, EL2 is using AArch64, [HCR_EL2](#).{E2H, TGE} is {1, 1} and the PE is in Non-secure EL0, the value is compared against [CONTEXTIDR_EL2](#).

This field resets to a value that is architecturally UNKNOWN.

When $DBGBCR<n>.BT==0b101x$ and EL2 implemented:

ContextID, bits [31:0]

Context ID value for comparison against [CONTEXTIDR](#).

This field resets to a value that is architecturally UNKNOWN.

When $DBGBCR<n>.BT==0b111x$ and EL2 implemented:

ContextID, bits [31:0]

Context ID value for comparison against [CONTEXTIDR_EL2](#).

This field resets to a value that is architecturally UNKNOWN.

Accessing the $DBGBVR<n>$

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p14, 0, <Rt>, c0, <CRm>, 4	000	100	0000	1110	n<3:0>

- <CRm> is in the range c0 - c15.

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	RW	n/a	RW
x	0	1	-	RW	RW	RW
x	1	1	-	n/a	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see:

- [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state.
- [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state.
- [Software Access debug event on page H3-5493](#) for accesses to this register taken to Debug state.

Subject to the prioritization rules:

- In both security states, and not dependent on other bits:
 - If `EDSCR.TDA==1`, `DBGOSLSR.OSLK==0`, and halting is allowed, accesses to this register from EL1 and EL2 generate a Software Access debug event.
- When EL2 is implemented and is using AArch64 and `SCR_EL3.NS == 1`:
 - If `MDCR_EL2.TDA==1`, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and `SCR_EL3.NS == 1`:
 - If `HDCR.TDA==1`, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
- When EL3 is implemented and is using AArch64:
 - If `MDCR_EL3.TDA==1`, accesses to this register from EL1 and EL2 are trapped to EL3.

G6.3.4 DBGBXVR<n>, Debug Breakpoint Extended Value Registers, n = 0 - 15

The DBGBXVR<n> characteristics are:

Purpose

Holds a value for use in breakpoint matching, to support VMID matching. Used in conjunction with a control register [DBGBCR<n>](#) and a value register [DBGBVR<n>](#), where EL2 is implemented and breakpoint n supports Context matching.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register DBGBXVR<n> is architecturally mapped to AArch64 System register [DBGBVR<n>_EL1](#)[63:32].

AArch32 System register DBGBXVR<n> is architecturally mapped to External register [DBGBVR<n>_EL1](#)[63:32].

Note

Writes to DBGBXVR<n> do not modify [DBGBVR<n>_EL1](#)[31:0].

This register is unallocated in any of the following cases:

- Breakpoint n is not implemented.
- Breakpoint n does not support Context matching.
- EL2 is not implemented.

For more information, see the description of the [DBGDIDR.CTX_CMPs](#) field.

This register is in the Cold reset domain. On a Cold reset RW fields in this register reset to architecturally UNKNOWN values. The register is not affected by a Warm reset.

Attributes

How this register is interpreted depends on the value of [DBGBCR<n>.BT](#).

- When [DBGBCR<n>.BT](#) is 0b10xx, this register holds a VMID.
- When [DBGBCR<n>.BT](#) is 0b11xx, this register holds a Context ID.

For other values of [DBGBCR<n>.BT](#), this register is RES0.

Field descriptions

The DBGBXVR<n> bit assignments are:

When [DBGBCR<n>.BT](#)==0b10xx and EL2 implemented:

Bits [31:16]

Reserved, RES0.

VMID[15:8], bits [15:8]

In ARMv8.2 and ARMv8.1

Extension to VMID[7:0]. See VMID[7:0] for more details.

This field resets to a value that is architecturally UNKNOWN.

In ARMv8.0.

Reserved, RES0.

VMID[7:0], bits [7:0]

VMID value for comparison.

The VMID is 8 bits in the following cases.

- EL2 is using AArch32.
- [ARMv8.1-VMID16](#) is not implemented.

When [ARMv8.1-VMID16](#) is implemented and EL2 is using AArch64, it is IMPLEMENTATION DEFINED whether the VMID is 8 bits or 16 bits.

VMID[15:8] is RES0 if any of the following applies:

- The implementation has an 8-bit VMID.
- [VTCCR_EL2.VS](#) has a value of 0.
- EL2 is using AArch32.

This field resets to a value that is architecturally UNKNOWN.

When $DBGBCR\langle n \rangle.BT == 0b11xx$ and EL2 implemented:

ContextID2, bits [31:0]

Context ID value for comparison against [CONTEXTIDR_EL2](#).

This field resets to a value that is architecturally UNKNOWN.

Accessing the $DBGXVR\langle n \rangle$

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p14, 0, <Rt>, c1, <CRm>, 1	000	001	0001	1110	n<3:0>

- <CRm> is in the range c0 - c15.

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	RW	n/a	RW
x	0	1	-	RW	RW	RW
x	1	1	-	n/a	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see:

- [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state.
- [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state.
- [Software Access debug event on page H3-5493](#) for accesses to this register taken to Debug state.

Subject to the prioritization rules:

- In both security states, and not dependent on other bits:
 - If `EDSCR.TDA==1`, `DBGOSLSR.OSLK==0`, and halting is allowed, accesses to this register from EL1 and EL2 generate a Software Access debug event.
- When EL2 is implemented and is using AArch64 and `SCR_EL3.NS == 1`:
 - If `MDCR_EL2.TDA==1`, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and `SCR_EL3.NS == 1`:
 - If `HDCR.TDA==1`, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
- When EL3 is implemented and is using AArch64:
 - If `MDCR_EL3.TDA==1`, accesses to this register from EL1 and EL2 are trapped to EL3.

G6.3.5 DBGCLAIMCLR, Debug Claim Tag Clear register

The DBGCLAIMCLR characteristics are:

Purpose

Used by software to read the values of the CLAIM tag bits, and to clear these bits to 0.
The architecture does not define any functionality for the CLAIM tag bits.

———— Note —————

CLAIM tags are typically used for communication between the debugger and target software.

Used in conjunction with the [DBGCLAIMSET](#) register.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register DBGCLAIMCLR is architecturally mapped to AArch64 System register [DBGCLAIMCLR_EL1](#).

AArch32 System register DBGCLAIMCLR is architecturally mapped to External register [DBGCLAIMCLR_EL1](#).

An implementation must include 8 CLAIM tag bits.

This register is in the Cold reset domain. See the CLAIM field description for the effect of a Cold reset on the value returned by this register. This register is not affected by a Warm reset.

Attributes

DBGCLAIMCLR is a 32-bit register.

Field descriptions

The DBGCLAIMCLR bit assignments are:

Bits [31:8]

Reserved, RAZ/SBZ. Software can rely on these bits reading as zero, and must use a should-be-zero policy on writes. Implementations must ignore writes.

CLAIM, bits [7:0]

Read or clear CLAIM tag bits. Reading this field returns the current value of the CLAIM tag bits.

Writing a 1 to one of these bits clears the corresponding CLAIM tag bit to 0. This is an indirect write to the CLAIM tag bits. A single write operation can clear multiple CLAIM tag bits to 0.

Writing 0 to one of these bits has no effect.

A cold reset clears the CLAIM tag bits to 0.

Accessing the DBGCLAIMCLR

This register can be read using MRC with the following syntax:

```
MRC <syntax>
```

This register can be written using MCR with the following syntax:

```
MCR <syntax>
```

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p14, 0, <Rt>, c7, c9, 6	000	110	0111	1110	1001

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	RW	n/a	RW
x	0	1	-	RW	RW	RW
x	1	1	-	n/a	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and SCR_EL3.NS == 1:
 - If MDCR_EL2.TDA==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HDCR.TDA==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
- When EL3 is implemented and is using AArch64:
 - If MDCR_EL3.TDA==1, accesses to this register from EL1 and EL2 are trapped to EL3.

G6.3.6 DBGCLAIMSET, Debug Claim Tag Set register

The DBGCLAIMSET characteristics are:

Purpose

Used by software to set the CLAIM tag bits to 1.

The architecture does not define any functionality for the CLAIM tag bits.

———— Note —————

CLAIM tags are typically used for communication between the debugger and target software.

Used in conjunction with the [DBGCLAIMCLR](#) register.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register DBGCLAIMSET is architecturally mapped to AArch64 System register [DBGCLAIMSET_EL1](#).

AArch32 System register DBGCLAIMSET is architecturally mapped to External register [DBGCLAIMSET_EL1](#).

An implementation must include 8 CLAIM tag bits.

Attributes

DBGCLAIMSET is a 32-bit register.

Field descriptions

The DBGCLAIMSET bit assignments are:

Bits [31:8]

Reserved, RAZ/SBZ. Software can rely on these bits reading as zero, and must use a should-be-zero policy on writes. Implementations must ignore writes.

CLAIM, bits [7:0]

Set CLAIM tag bits. RAO.

Writing a 1 to one of these bits sets the corresponding CLAIM tag bit to 1. This is an indirect write to the CLAIM tag bits. A single write operation can set multiple CLAIM tag bits to 1.

Writing 0 to one of these bits has no effect.

A cold reset clears the CLAIM tag bits to 0.

Accessing the DBGCLAIMSET

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p14, 0, <Rt>, c7, c8, 6	000	110	0111	1110	1000

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	RW	n/a	RW
x	0	1	-	RW	RW	RW
x	1	1	-	n/a	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and SCR_EL3.NS == 1:
 - If MDCR_EL2.TDA==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HDCR.TDA==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
- When EL3 is implemented and is using AArch64:
 - If MDCR_EL3.TDA==1, accesses to this register from EL1 and EL2 are trapped to EL3.

G6.3.7 DBGDCCINT, DCC Interrupt Enable Register

The DBGDCCINT characteristics are:

Purpose

Enables interrupt requests to be signaled based on the DCC status flags.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register DBGDCCINT is architecturally mapped to AArch64 System register [MDCCINT_EL1](#).

This register is in the Warm reset domain. Some or all RW fields of this register have defined reset values. On a Warm or Cold reset these apply only if the PE resets into an Exception level that is using AArch32. Otherwise, on a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

DBGDCCINT is a 32-bit register.

Field descriptions

The DBGDCCINT bit assignments are:

Bit [31]

Reserved, RES0.

RX, bit [30]

DCC interrupt request enable control for DTRRX. Enables a common COMMIRQ interrupt request to be signaled based on the DCC status flags.

0 No interrupt request generated by DTRRX.

1 Interrupt request will be generated on RXfull == 1.

If legacy COMMRX and COMMTX signals are implemented, then these are not affected by the value of this bit.

When this register has an architecturally-defined reset value, this field resets to 0.

TX, bit [29]

DCC interrupt request enable control for DTRTX. Enables a common COMMIRQ interrupt request to be signaled based on the DCC status flags.

0 No interrupt request generated by DTRTX.

1 Interrupt request will be generated on TXfull == 0.

If legacy COMMRX and COMMTX signals are implemented, then these are not affected by the value of this bit.

When this register has an architecturally-defined reset value, this field resets to 0.

Bits [28:0]

Reserved, RES0.

Accessing the DBGDCCINT

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p14, 0, <Rt>, c0, c2, 0	000	000	0000	1110	0010

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	RW	n/a	RW
x	0	1	-	RW	RW	RW
x	1	1	-	n/a	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and SCR_EL3.NS == 1:
 - If MDCR_EL2.TDA==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HDCR.TDA==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
- When EL3 is implemented and is using AArch64:
 - If MDCR_EL3.TDA==1, accesses to this register from EL1 and EL2 are trapped to EL3.

G6.3.8 DBGDEVID, Debug Device ID register 0

The DBGDEVID characteristics are:

Purpose

Adds to the information given by the [DBGDIDR](#) by describing other features of the debug implementation.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

This register is required in all implementations.

Attributes

DBGDEVID is a 32-bit register.

Field descriptions

The DBGDEVID bit assignments are:

CIDMask, bits [31:28]

Indicates the level of support for the Context ID matching breakpoint masking capability. Permitted values of this field are:

0000 Context ID masking is not implemented.

0001 Context ID masking is implemented.

All other values are reserved. The value of this for ARMv8 is 0000.

AuxRegs, bits [27:24]

Indicates support for Auxiliary registers. Permitted values for this field are:

0000 None supported.

0001 Support for External Debug Auxiliary Control Register, [EDACR](#).

All other values are reserved.

DoubleLock, bits [23:20]

Indicates the presence of the [DBGOSDLR](#), OS Double Lock Register. Permitted values of this field are:

0000 The [DBGOSDLR](#) is not present.

0001 The [DBGOSDLR](#) is present.

All other values are reserved. The value of this for ARMv8 is 0001.

VirtExtns, bits [19:16]

Indicates whether EL2 is implemented. Permitted values of this field are:

0000 EL2 is not implemented.

0001 EL2 is implemented.

All other values are reserved.

VectorCatch, bits [15:12]

Defines the form of Vector Catch exception implemented. Permitted values of this field are:

- 0000 Address matching Vector Catch exception implemented.
 - 0001 Exception matching Vector Catch exception implemented.
- All other values are reserved.

BPAddrMask, bits [11:8]

Indicates the level of support for the instruction address matching breakpoint masking capability. Permitted values of this field are:

- 0000 Breakpoint address masking might be implemented. If not implemented, [DBGBCR<n>](#)[28:24] is RAZ/WI.
 - 0001 Breakpoint address masking is implemented.
 - 1111 Breakpoint address masking is not implemented. [DBGBCR<n>](#)[28:24] is RES0.
- All other values are reserved. The value of this for ARMv8 is 1111.

WPAAddrMask, bits [7:4]

Indicates the level of support for the data address matching watchpoint masking capability. Permitted values of this field are:

- 0000 Watchpoint address masking might be implemented. If not implemented, [DBGWCR<n>](#).MASK (Address mask) is RAZ/WI.
- 0001 Watchpoint address masking is implemented.
- 1111 Watchpoint address masking is not implemented. [DBGWCR<n>](#).MASK (Address mask) is RES0.

All other values are reserved. The value of this for ARMv8 is 0001.

PCSample, bits [3:0]

Indicates the level of PC Sample-based Profiling support using external debug registers. Permitted values of this field are:

- 0000 Architecture-defined form of PC Sample-based Profiling not implemented using external debug registers.
- 0010 Only [EDPCSR](#) and [EDCIDSR](#) are implemented. This option is only permitted if EL3 and EL2 are not implemented.
- 0011 [EDPCSR](#), [EDCIDSR](#), and [EDVIDSR](#) are implemented.

All other values are reserved.

From ARMv8.2 onwards, the only permitted value is 0b0000. The architecture defines the functionality in a different set of registers, see [PMDEVID](#).

Accessing the DBGDEVID

This register can be read using MRC with the following syntax:

MRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p14, 0, <Rt>, c7, c2, 7	000	111	0111	1110	0010

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	RO	n/a	RO
x	0	1	-	RO	RO	RO
x	1	1	-	n/a	RO	RO

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and SCR_EL3.NS == 1:
 - If MDCR_EL2.TDA==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HDCR.TDA==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
- When EL3 is implemented and is using AArch64:
 - If MDCR_EL3.TDA==1, read accesses to this register from EL1 and EL2 are trapped to EL3.

G6.3.9 DBGDEVID1, Debug Device ID register 1

The DBGDEVID1 characteristics are:

Purpose

Adds to the information given by the [DBGDIDR](#) by describing other features of the debug implementation.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states. This register is required in all implementations.

Attributes

DBGDEVID1 is a 32-bit register.

Field descriptions

The DBGDEVID1 bit assignments are:

Bits [31:4]

Reserved, RES0.

PCSROffset, bits [3:0]

This field indicates the offset applied to PC samples returned by reads of [EDPCSR](#). Permitted values of this field in ARMv8 are:

- 0000 [EDPCSR](#) not implemented.
- 0010 [EDPCSR](#) implemented. Samples have no offset applied and do not sample the instruction set state in AArch32 state.

Note

In ARMv7, a PCSROffset value of 0000 has an alternative meaning that [EDPCSR](#) is implemented and returns values that have an offset applied and indicate the Instruction set state. This implementation option is not permitted in ARMv8.

From ARMv8.2 onwards, the only permitted value is 0b0000. The architecture defines the functionality in a different set of registers, see [PMDEVID](#).

Accessing the DBGDEVID1

This register can be read using MRC with the following syntax:

MRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p14, 0, <Rt>, c7, c1, 7	000	111	0111	1110	0001

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	RO	n/a	RO
x	0	1	-	RO	RO	RO
x	1	1	-	n/a	RO	RO

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and SCR_EL3.NS == 1:
 - If MDCR_EL2.TDA==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HDCR.TDA==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
- When EL3 is implemented and is using AArch64:
 - If MDCR_EL3.TDA==1, read accesses to this register from EL1 and EL2 are trapped to EL3.

G6.3.10 DBGDEVID2, Debug Device ID register 2

The DBGDEVID2 characteristics are:

Purpose

Reserved for future descriptions of features of the debug implementation.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

Attributes

DBGDEVID2 is a 32-bit register.

Field descriptions

The DBGDEVID2 bit assignments are:

Bits [31:0]

Reserved, RES0.

Accessing the DBGDEVID2

This register can be read using MRC with the following syntax:

MRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p14, 0, <Rt>, c7, c0, 7	000	111	0111	1110	0000

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	RO	n/a	RO
x	0	1	-	RO	RO	RO
x	1	1	-	n/a	RO	RO

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and $SCR_EL3.NS == 1$:
 - If $MDCR_EL2.TDA == 1$, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $HDCR.TDA == 1$, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
- When EL3 is implemented and is using AArch64:
 - If $MDCR_EL3.TDA == 1$, read accesses to this register from EL1 and EL2 are trapped to EL3.

G6.3.11 DBGDIDR, Debug ID Register

The DBGDIDR characteristics are:

Purpose

Specifies which version of the Debug architecture is implemented, and some features of the debug implementation.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

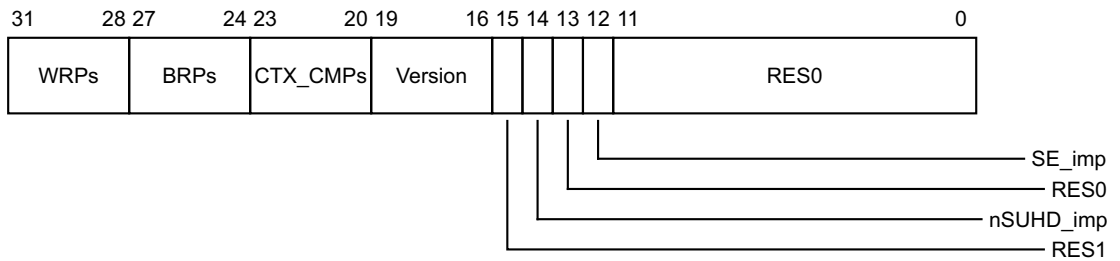

If EL1 cannot use AArch32 then the implementation of this register is OPTIONAL and deprecated.

Attributes

DBGDIDR is a 32-bit register.

Field descriptions

The DBGDIDR bit assignments are:

WRPs, bits [31:28]

The number of watchpoints implemented, minus 1.

Permitted values of this field are from 0b0001 for 2 implemented watchpoints, to 0b1111 for 16 implemented watchpoints.

The value of 0b0000 is reserved.

If AArch64 is implemented, this field has the same value as [ID_AA64DFR0_EL1.WRPs](#).

BRPs, bits [27:24]

The number of breakpoints implemented, minus 1.

Permitted values of this field are from 0b0001 for 2 implemented breakpoint, to 0b1111 for 16 implemented breakpoints.

The value of 0b0000 is reserved.

If AArch64 is implemented, this field has the same value as [ID_AA64DFR0_EL1.BRPs](#).

CTX_CMPs, bits [23:20]

The number of breakpoints that can be used for Context matching, minus 1.

Permitted values of this field are from 0b0000 for 1 Context matching breakpoint, to 0b1111 for 16 Context matching breakpoints.

The Context matching breakpoints must be the highest addressed breakpoints. For example, if six breakpoints are implemented and two are Context matching breakpoints, they must be breakpoints 4 and 5.

If AArch64 is implemented, this field has the same value as [ID_AA64DFR0_EL1.CTX_CMPs](#).

Version, bits [19:16]

The Debug architecture version. Defined values are:

0001	ARMv6, v6 Debug architecture.
0010	ARMv6, v6.1 Debug architecture.
0011	ARMv7, v7 Debug architecture, with baseline CP14 registers implemented.
0100	ARMv7, v7 Debug architecture, with all CP14 registers implemented.
0101	ARMv7, v7.1 Debug architecture.
0110	ARMv8, v8 Debug architecture.
0111	ARMv8.1, v8 Debug architecture, with Virtualization Host Extensions.
1000	ARMv8.2, v8.2 Debug architecture.

All other values are reserved.

- In an ARMv8.0 implementation, the only permitted value is 0110.
- In an ARMv8.1 implementation that includes [ARMv8.1-VHE](#), the only permitted value is 0111.
- In an ARMv8.1 implementation that does not include [ARMv8.1-VHE](#), the permitted values are 0110 and 0111.
- In an ARMv8.2 implementation, the only permitted value is 1000.

Bit [15]

Reserved, RES1.

nSUHD_imp, bit [14]

In ARMv7-A, was Secure User Halting Debug not implemented.

The value of this bit must match the value of the SE_imp bit.

Bit [13]

Reserved, RES0.

SE_imp, bit [12]

EL3 implemented. The meanings of the values of this bit are:

0	EL3 not implemented.
1	EL3 implemented.

The value of this bit must match the value of the nSUHD_imp bit.

Bits [11:0]

Reserved, RES0.

Accessing the DBGDIDR

This register can be read using MRC with the following syntax:

MRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p14, 0, <Rt>, c0, c0, 0	000	000	0000	1110	0000

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	RO	RO	n/a	RO
x	0	1	RO	RO	RO	RO
x	1	1	RO	n/a	RO	RO

ARM deprecates any access to this register from EL0.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- In both security states, and not dependent on other bits:
 - If `DBGDSCRExt.UDCCdis==1`, read accesses to this register from EL0 are trapped to Undefined mode.
 - If `MDSCR_EL1.TDCC==1`, read accesses to this register from EL0 are trapped to EL1.
- When EL2 is implemented and is using AArch64 and `SCR_EL3.NS == 1`:
 - If `MDCR_EL2.TDA==1`, Non-secure read accesses to this register from EL0 and EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and `SCR_EL3.NS == 1`:
 - If `HDCR.TDA==1`, Non-secure read accesses to this register from EL0 and EL1 are trapped to Hyp mode.
- When EL3 is implemented and is using AArch64:
 - If `MDCR_EL3.TDA==1`, read accesses to this register from EL0, EL1, and EL2 are trapped to EL3.

G6.3.12 DBGDRAR, Debug ROM Address Register

The DBGDRAR characteristics are:

Purpose

Defines the base physical address of a 4KB-aligned memory-mapped debug component, usually a ROM table that locates and describes the memory-mapped debug components in the system. ARMv8 deprecates any use of this register.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register DBGDRAR is architecturally mapped to AArch64 System register [MDRAR_EL1](#).

If EL1 cannot use AArch32 then the implementation of this register is OPTIONAL and deprecated.

Attributes

DBGDRAR is a 64-bit register that can also be accessed as a 32-bit value. If it is accessed as a 32-bit register, bits [31:0] are read.

Field descriptions

The DBGDRAR bit assignments are:

When accessing as a 32-bit register:

ROMADDR[31:12], bits [31:12]

Bits[31:12] of the ROM table physical address. Bits [11:0] of the address are zero.

In an implementation that includes EL3, ROMADDR is an address in Non-secure memory. It is IMPLEMENTATION DEFINED whether the ROM table is also accessible in Secure memory.

Bits [11:2]

Reserved, RES0.

Valid, bits [1:0]

This field indicates whether the ROM Table address is valid. The permitted values of this field are:

00 ROM Table address is not valid. Software must ignore ROMADDR.

11 ROM Table address is valid.

Other values are reserved.

When accessing as a 64-bit register:

Bits [63:48]

Reserved, RES0.

ROMADDR[47:12], bits [47:12]

Bits[47:12] of the ROM table physical address.

If the physical address size in bits (PAsize) is less than 48 then the register bits corresponding to ROMADDR [47:PAsize] are RES0.

Bits [11:0] of the ROM table physical address are zero.

ARM strongly recommends that bits ROMADDR[(PAsize-1):32] are zero in any system that supports AArch32 at the highest implemented Exception level.

In an implementation that includes EL3, ROMADDR is an address in Non-secure memory. It is IMPLEMENTATION DEFINED whether the ROM table is also accessible in Secure memory.

Bits [11:2]

Reserved, RES0.

Valid, bits [1:0]

This field indicates whether the ROM Table address is valid. The permitted values of this field are:

00 ROM Table address is not valid. Software must ignore ROMADDR.

11 ROM Table address is valid.

Other values are reserved.

Accessing the DBGDRAR

This register can be read using MRC with the following syntax:

MRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p14, 0, <Rt>, c1, c0, 0	000	000	0001	1110	0000

This register can be read using MRRC with the following syntax:

MRRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	coproc	CRm
p14, 0, <Rt>, <Rt2>, c1	0000	1110	0001

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	RO	RO	n/a	RO
x	0	1	RO	RO	RO	RO
x	1	1	RO	n/a	RO	RO

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- In both security states, and not dependent on other bits:
 - If `DBGDSCRExt.UDCCdis`==1, read accesses to this register from EL0 are trapped to Undefined mode.
 - If `MDSCR_EL1.TDCC`==1, read accesses to this register from EL0 are trapped to EL1.
- When EL2 is implemented and is using AArch64 and `SCR_EL3.NS` == 1:
 - If `MDCR_EL2.TDRA`==1, Non-secure read accesses to this register from EL0 and EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and `SCR_EL3.NS` == 1:
 - If `HDCR.TDRA`==1, Non-secure read accesses to this register from EL0 and EL1 are trapped to Hyp mode.

G6.3.13 DBGDSAR, Debug Self Address Register

The DBGDSAR characteristics are:

Purpose

In earlier versions of the ARM Architecture, this register defines the offset from the base address defined in [DBGDRAR](#) of the physical base address of the debug registers for the PE. ARMv8 deprecates any use of this register.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

If EL1 cannot use AArch32 then the implementation of this register is OPTIONAL and deprecated.

Attributes

DBGDSAR is a 64-bit register that can also be accessed as a 32-bit value. If it is accessed as a 32-bit register, bits [31:0] are read.

Field descriptions

The DBGDSAR bit assignments are:

When accessing as a 32-bit register:

Offset, bits [31:0]

This register value is RAZ.

When accessing as a 64-bit register:

Offset, bits [63:0]

This register value is RAZ.

Accessing the DBGDSAR

This register can be read using MRC with the following syntax:

MRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p14, 0, <Rt>, c2, c0, 0	000	000	0010	1110	0000

This register can be read using MRRC with the following syntax:

MRRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	coproc	CRm
p14, 0, <Rt>, <Rt2>, c2	0000	1110	0010

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	RO	RO	n/a	RO
x	0	1	RO	RO	RO	RO
x	1	1	RO	n/a	RO	RO

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- In both security states, and not dependent on other bits:
 - If `DBGDSCRExt.UDCCdis==1`, read accesses to this register from EL0 are trapped to Undefined mode.
 - If `MDSR_EL1.TDCC==1`, read accesses to this register from EL0 are trapped to EL1.
- When EL2 is implemented and is using AArch64 and `SCR_EL3.NS == 1`:
 - If `MDCR_EL2.TDRA==1`, Non-secure read accesses to this register from EL0 and EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and `SCR_EL3.NS == 1`:
 - If `HDCR.TDRA==1`, Non-secure read accesses to this register from EL0 and EL1 are trapped to Hyp mode.
- When EL3 is implemented and is using AArch64:
 - If `MDCR_EL3.TDA==1`, read accesses to this register from EL0, EL1, and EL2 are trapped to EL3.

G6.3.14 DBGDSCRext, Debug Status and Control Register, External View

The DBGDSCRext characteristics are:

Purpose

Main control register for the debug implementation.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register DBGDSCRext is architecturally mapped to AArch64 System register [MDSR_EL1](#).

This register is required in all implementations.

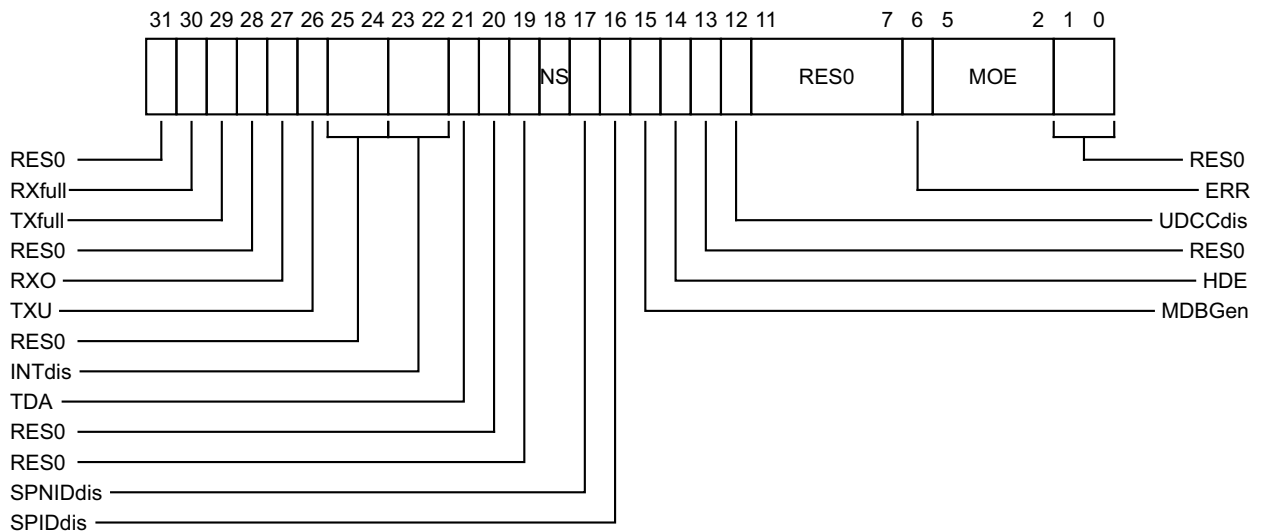

This register is in the Warm reset domain. Some or all RW fields of this register have defined reset values. On a Warm or Cold reset these apply only if the PE resets into an Exception level that is using AArch32. Otherwise, on a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

DBGDSCRext is a 32-bit register.

Field descriptions

The DBGDSCRext bit assignments are:

Bit [31]

Reserved, RES0.

RXfull, bit [30]

DTRRX full. Used for save/restore of [EDSCR.RXfull](#).

When [DBGOSLSR.OSLK](#) == 0 (the OS lock is unlocked), this bit is RO, and software must treat it as UNK/SBZP.

When [DBGOSLSR.OSLK](#) == 1 (the OS lock is locked), this bit is RW and holds the value of [EDSCR.RXfull](#).

ARM deprecates use of this bit other than for save/restore. Use [DBGDSCRint](#) to access the DTRRX full status.

Reads and writes of this bit are indirect accesses to [EDSCR.RXfull](#).

The architected behavior of this field determines the value it returns after a reset.

TXfull, bit [29]

DTRTX full. Used for save/restore of [EDSCR.TXfull](#).

When [DBGOSLSR.OSLK](#) == 0 (the OS lock is unlocked), this bit is RO, and software must treat it as UNK/SBZP.

When [DBGOSLSR.OSLK](#) == 1 (the OS lock is locked), this bit is RW and holds the value of [EDSCR.TXfull](#).

ARM deprecates use of this bit other than for save/restore. Use [DBGDSCRint](#) to access the DTRTX full status.

Reads and writes of this bit are indirect accesses to [EDSCR.TXfull](#).

The architected behavior of this field determines the value it returns after a reset.

Bit [28]

Reserved, RES0.

RXO, bit [27]

Used for save/restore of [EDSCR.RXO](#).

When [DBGOSLSR.OSLK](#) == 0 (the OS lock is unlocked), this bit is RO, and software must treat it as UNK/SBZP.

When [DBGOSLSR.OSLK](#) == 1 (the OS lock is locked), this bit is RW and holds the value of [EDSCR.RXO](#).

Reads and writes of this bit are indirect accesses to [EDSCR.RXO](#).

The architected behavior of this field determines the value it returns after a reset.

TXU, bit [26]

Used for save/restore of [EDSCR.TXU](#).

When [DBGOSLSR.OSLK](#) == 0 (the OS lock is unlocked), this bit is RO, and software must treat it as UNK/SBZP.

When [DBGOSLSR.OSLK](#) == 1 (the OS lock is locked), this bit is RW and holds the value of [EDSCR.TXU](#).

Reads and writes of this bit are indirect accesses to [EDSCR.TXU](#).

The architected behavior of this field determines the value it returns after a reset.

Bits [25:24]

Reserved, RES0.

INTdis, bits [23:22]

Used for save/restore of [EDSCR.INTdis](#).

When [DBGOSLSR.OSLK](#) == 0 (the OS lock is unlocked), this field is RO, and software must treat it as UNK/SBZP.

When [DBGOSLSR.OSLK](#) == 1 (the OS lock is locked), this field is RW and holds the value of [EDSCR.INTdis](#).

Reads and writes of this field are indirect accesses to [EDSCR.INTdis](#).

The architected behavior of this field determines the value it returns after a reset.

TDA, bit [21]

Used for save/restore of [EDSCR.TDA](#).

When [DBGOSLSR.OSLK](#) == 0 (the OS lock is unlocked), this bit is RO, and software must treat it as UNK/SBZP.

When [DBGOSLSR.OSLK](#) == 1 (the OS lock is locked), this bit is RW and holds the value of [EDSCR.TDA](#).

Reads and writes of this bit are indirect accesses to [EDSCR.TDA](#).
The architected behavior of this field determines the value it returns after a reset.

Bit [20]

Reserved, RES0.

SC2, bit [19]

In ARMv8.1

Used for save/restore of [EDSCR.SC2](#).

When [DBGOSLSR.OSLK](#) == 0 (the OS lock is unlocked), this bit is RO, and software must treat it as UNK/SBZP.

When [DBGOSLSR.OSLK](#) == 1 (the OS lock is locked), this bit is RW and holds the value of [EDSCR.SC2](#).

Reads and writes of this bit are indirect accesses to [EDSCR.SC2](#).

If the PC Sample-based Profiling Extension is not implemented, then this field is RES0.

In ARMv8.2 and ARMv8.0.

Reserved, RES0.

NS, bit [18]

Non-secure status. Returns the inverse of `IsSecure()`. This bit is RO.

ARM deprecates use of this field.

SPNIDdis, bit [17]

Secure privileged profiling disabled status bit. This bit is RO. Permitted values are:

- 0 If EL3 is implemented, profiling allowed in Secure privileged modes.
- 1 If EL3 is implemented, profiling prohibited in Secure privileged modes.

This field is RES0 if EL3 is not implemented.

- This field is RES1 if either:
 - EL3 is using AArch64 and the Effective value of [SCR_EL3.NS](#) is 1.
 - EL3 is using AArch32 and the Effective value of [SCR.NS](#) is 1.
- Otherwise, the field is RES0 if any of the following applies, and RES1 otherwise:
 - [ARMv8.2-Debug](#) is not implemented and `ExternalSecureNoninvasiveDebugEnabled()` returns TRUE.
 - EL3 is using AArch32 and the value of [SDCR.SPME](#) is 1.
 - EL3 is using AArch64 and the value of [MDCR_EL3.SPME](#) is 1.

ARM deprecates use of this field.

SPIDdis, bit [16]

Secure privileged AArch32 invasive self-hosted debug disabled status bit. This bit is RO and depends on the value of [SDCR.SPD](#) and the pseudocode function `AArch32.SelfHostedSecurePrivilegedInvasiveDebugEnabled()`. Permitted values are:

- 0 Self-hosted debug enabled in Secure privileged AArch32 modes.
- 1 Self-hosted debug disabled in Secure privileged AArch32 modes.

This bit reads as 1 if any of the following is true and reads as 0 otherwise:

- [SDCR.SPD](#) has the value 10.
- [SDCR.SPD](#) has the value 00 and `AArch32.SelfHostedSecurePrivilegedInvasiveDebugEnabled()` returns FALSE.

ARM deprecates use of this field.

MDBGen, bit [15]

Monitor debug events enable. Enable Breakpoint, Watchpoint, and Vector Catch exceptions.

0 Breakpoint, Watchpoint, and Vector Catch exceptions disabled.

1 Breakpoint, Watchpoint, and Vector Catch exceptions enabled.

When this register has an architecturally-defined reset value, this field resets to 0.

HDE, bit [14]

Used for save/restore of [EDSCR.HDE](#).

When [DBGOSLSR.OSLK](#) == 0 (the OS lock is unlocked), this bit is RO, and software must treat it as UNK/SBZP.

When [DBGOSLSR.OSLK](#) == 1 (the OS lock is locked), this bit is RW and holds the value of [EDSCR.HDE](#).

Reads and writes of this bit are indirect accesses to [EDSCR.HDE](#).

The architected behavior of this field determines the value it returns after a reset.

Bit [13]

Reserved, RES0.

UDCCdis, bit [12]

Traps EL0 accesses to the DCC registers to Undefined mode.

0 This control does not cause any instructions to be trapped.

1 EL0 accesses to the [DBGDSCRint](#), [DBGDTRRXint](#), [DBGDTRTXint](#), [DBGDIDR](#), [DBGDSAR](#), and [DBGDRAR](#) are trapped to Undefined mode.

———— Note ————

All accesses to these registers are trapped, including LDC and STC accesses to [DBGDTRTXint](#) and [DBGDTRRXint](#), and MRRC accesses to [DBGDSAR](#) and [DBGDRAR](#).

Traps of EL0 accesses to the [DBGDTRRXint](#) and [DBGDTRTXint](#) are ignored in Debug state.

When this register has an architecturally-defined reset value, this field resets to 0.

Bits [11:7]

Reserved, RES0.

ERR, bit [6]

Used for save/restore of [EDSCR.ERR](#).

When [DBGOSLSR.OSLK](#) == 0 (the OS lock is unlocked), this bit is RO, and software must treat it as UNK/SBZP.

When [DBGOSLSR.OSLK](#) == 1 (the OS lock is locked), this bit is RW and holds the value of [EDSCR.ERR](#).

Reads and writes of this bit are indirect accesses to [EDSCR.ERR](#).

The architected behavior of this field determines the value it returns after a reset.

MOE, bits [5:2]

Method of Entry for debug exception. When a debug exception is taken to an Exception level using AArch32, this field is set to indicate the event that caused the exception:

0001 Breakpoint

0011 Software breakpoint (BKPT) instruction

0101 Vector catch

1010 Watchpoint

This field resets to a value that is architecturally UNKNOWN.

Bits [1:0]

Reserved, RES0.

Accessing the DBGDSCRExt

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p14, 0, <Rt>, c0, c2, 2	000	010	0000	1110	0010

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	RW	n/a	RW
x	0	1	-	RW	RW	RW
x	1	1	-	n/a	RW	RW

Individual fields within this register might have restricted accessibility when `DBGOSLSR.OSLK == 0` (the OS lock is unlocked.) See the field descriptions for more detail.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and `SCR_EL3.NS == 1`:
 - If `MDCR_EL2.TDA==1`, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and `SCR_EL3.NS == 1`:
 - If `HDCR.TDA==1`, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
- When EL3 is implemented and is using AArch64:
 - If `MDCR_EL3.TDA==1`, accesses to this register from EL1 and EL2 are trapped to EL3.

G6.3.15 DBGDSCRint, Debug Status and Control Register, Internal View

The DBGDSCRint characteristics are:

Purpose

Main control register for the debug implementation. This is an internal, read-only view.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

This register is required in all implementations.

DBGDSCRint.{NS, SPNIDdis, SPIDdis, MDBGen, UDCCdis, MOE} are UNKNOWN when the register is accessed at EL0. However, although these values are not accessible at EL0 by instructions that are neither UNPREDICTABLE nor return UNKNOWN values, it is permissible for an implementation to return the values of DBGDSCRext.{NS, SPNIDdis, SPIDdis, MDBGen, UDCCdis, MOE} for these fields at EL0.

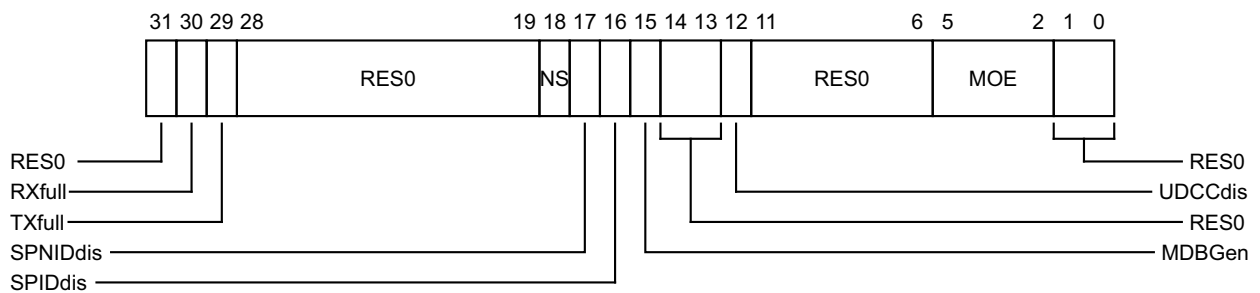

It is also permissible for an implementation to return the same values as defined for a read of DBGDSCRint at EL1 or above. (This is the case even if the implementation does not support AArch32 at EL1 or above.)

Attributes

DBGDSCRint is a 32-bit register.

Field descriptions

The DBGDSCRint bit assignments are:

Bit [31]

Reserved, RES0.

RXfull, bit [30]

DTRRX full. Read-only view of the equivalent bit in the [EDSCR](#).

TXfull, bit [29]

DTRTX full. Read-only view of the equivalent bit in the [EDSCR](#).

Bits [28:19]

Reserved, RES0.

NS, bit [18]

Non-secure status.

Read-only view of the equivalent bit in the [DBGDSCRext](#). ARM deprecates use of this field.

SPNIDdis, bit [17]

Secure privileged non-invasive debug disable.

Read-only view of the equivalent bit in the [DBGDSCRext](#). ARM deprecates use of this field.

SPIDdis, bit [16]

Secure privileged invasive debug disable.

Read-only view of the equivalent bit in the [DBGDSCRext](#). ARM deprecates use of this field.

MDBGGen, bit [15]

Monitor debug events enable.

Read-only view of the equivalent bit in the [DBGDSCRext](#).

Bits [14:13]

Reserved, RES0.

UDCCdis, bit [12]

User mode access to Debug Communications Channel disable.

Read-only view of the equivalent bit in the [DBGDSCRext](#). ARM deprecates use of this field.

Bits [11:6]

Reserved, RES0.

MOE, bits [5:2]

Method of Entry for debug exception. When a debug exception is taken to an Exception level using AArch32, this field is set to indicate the event that caused the exception:

- 0001 Breakpoint
- 0011 Software breakpoint (BKPT) instruction
- 0101 Vector catch
- 1010 Watchpoint

Read-only view of the equivalent bit in the [DBGDSCRext](#).

Bits [1:0]

Reserved, RES0.

Accessing the DBGDSCRint

This register can be read using MRC with the following syntax:

MRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p14, 0, <Rt>, c0, c1, 0	000	000	0000	1110	0001

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	RO	RO	n/a	RO
x	0	1	RO	RO	RO	RO
x	1	1	RO	n/a	RO	RO

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- In both security states, and not dependent on other bits:
 - If `DBGDSCRExt.UDCCdis==1`, read accesses to this register from EL0 are trapped to Undefined mode.
 - If `MDSCR_EL1.TDCC==1`, read accesses to this register from EL0 are trapped to EL1.
- When EL2 is implemented and is using AArch64 and `SCR_EL3.NS == 1`:
 - If `MDCR_EL2.TDA==1`, Non-secure read accesses to this register from EL0 and EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and `SCR_EL3.NS == 1`:
 - If `HDCR.TDA==1`, Non-secure read accesses to this register from EL0 and EL1 are trapped to Hyp mode.
- When EL3 is implemented and is using AArch64:
 - If `MDCR_EL3.TDA==1`, read accesses to this register from EL0, EL1, and EL2 are trapped to EL3.

G6.3.16 DBGDTRRText, Debug OS Lock Data Transfer Register, Receive, External View

The DBGDTRRText characteristics are:

Purpose

Used for save/restore of [DBGDTRRXint](#). It is a component of the Debug Communications Channel.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register DBGDTRRText is architecturally mapped to AArch64 System register [OSDTRRX_EL1](#).

Attributes

DBGDTRRText is a 32-bit register.

Field descriptions

The DBGDTRRText bit assignments are:

Bits [31:0]

Update DTRRX without side-effect.

Writes to this register update the value in DTRRX and do not change RXfull.

Reads of this register return the last value written to DTRRX and do not change RXfull.

For the full behavior of the Debug Communications Channel, see [Chapter H4 The Debug Communication Channel and Instruction Transfer Register](#).

This field resets to a value that is architecturally UNKNOWN.

Accessing the DBGDTRRText

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p14, 0, <Rt>, c0, c0, 2	000	010	0000	1110	0000

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	RW	n/a	RW
x	0	1	-	RW	RW	RW
x	1	1	-	n/a	RW	RW

ARM deprecates reads and writes of DBGDTRRXext through the System register interface when the OS lock is unlocked.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and SCR_EL3.NS == 1:
 - If MDCR_EL2.TDA==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HDCR.TDA==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
- When EL3 is implemented and is using AArch64:
 - If MDCR_EL3.TDA==1, accesses to this register from EL1 and EL2 are trapped to EL3.

G6.3.17 DBGDTRRXint, Debug Data Transfer Register, Receive

The DBGDTRRXint characteristics are:

Purpose

Transfers data from an external debugger to the PE. For example, it is used by a debugger transferring commands and data to a debug target. It is a component of the Debug Communications Channel.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register DBGDTRRXint is architecturally mapped to AArch64 System register [DBGDTRRX_ELO](#).

AArch32 System register DBGDTRRXint is architecturally mapped to External register [DBGDTRRX_ELO](#).

This register is in the Cold reset domain. On a Cold reset RW fields in this register reset to architecturally UNKNOWN values. The register is not affected by a Warm reset.

Attributes

DBGDTRRXint is a 32-bit register.

Field descriptions

The DBGDTRRXint bit assignments are:

Bits [31:0]

Update DTRRX.

If RXfull is set to 1, then reads of this register return the last value written to DTRRX and clear RXfull to 0.

For the full behavior of the Debug Communications Channel, see [Chapter H4 The Debug Communication Channel and Instruction Transfer Register](#).

This field resets to a value that is architecturally UNKNOWN.

Accessing the DBGDTRRXint

This register can be read using MRC with the following syntax:

MRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p14, 0, <Rt>, c0, c5, 0	000	000	0000	1110	0101

Data can be stored to memory from this register using [STC](#).

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	RO	RO	n/a	RO
x	0	1	RO	RO	RO	RO
x	1	1	RO	n/a	RO	RO

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules, in Non-debug state:

- In both security states, and not dependent on other bits:
 - If `DBGDSCRExt.UDCCdis==1`, read accesses to this register from EL0 are trapped to Undefined mode.
 - If `MDSCR_EL1.TDCC==1`, read accesses to this register from EL0 are trapped to EL1.
- When EL2 is implemented and is using AArch64 and `SCR_EL3.NS == 1`:
 - If `MDCR_EL2.TDA==1`, Non-secure read accesses to this register from EL0 and EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and `SCR_EL3.NS == 1`:
 - If `HDCR.TDA==1`, Non-secure read accesses to this register from EL0 and EL1 are trapped to Hyp mode.
- When EL3 is implemented and is using AArch64:
 - If `MDCR_EL3.TDA==1`, read accesses to this register from EL0, EL1, and EL2 are trapped to EL3.

———— **Note** —————

Read accesses to this register are not trapped in Debug state.

G6.3.18 DBGDTRTXext, Debug OS Lock Data Transfer Register, Transmit

The DBGDTRTXext characteristics are:

Purpose

Used for save/restore of [DBGDTRTXint](#). It is a component of the Debug Communication Channel.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register DBGDTRTXext is architecturally mapped to AArch64 System register [OSDTRTX_EL1](#).

Attributes

DBGDTRTXext is a 32-bit register.

Field descriptions

The DBGDTRTXext bit assignments are:

Bits [31:0]

Return DTRTX without side-effect.

Reads of this register return the value in DTRTX and do not change TXfull.

Writes of this register update the value in DTRTX and do not change TXfull.

For the full behavior of the Debug Communications Channel, see [Chapter H4 The Debug Communication Channel and Instruction Transfer Register](#).

This field resets to a value that is architecturally UNKNOWN.

Accessing the DBGDTRTXext

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p14, 0, <Rt>, c0, c3, 2	000	010	0000	1110	0011

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	RW	n/a	RW
x	0	1	-	RW	RW	RW
x	1	1	-	n/a	RW	RW

ARM deprecates reads and writes of DBGDTRTXext through the System register interface when the OS lock is unlocked.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and SCR_EL3.NS == 1:
 - If MDCR_EL2.TDA==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HDCR.TDA==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
- When EL3 is implemented and is using AArch64:
 - If MDCR_EL3.TDA==1, accesses to this register from EL1 and EL2 are trapped to EL3.

G6.3.19 DBGDTRTXint, Debug Data Transfer Register, Transmit

The DBGDTRTXint characteristics are:

Purpose

Transfers data from the PE to an external debugger. For example, it is used by a debug target to transfer data to the debugger. It is a component of the Debug Communication Channel.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register DBGDTRTXint is architecturally mapped to AArch64 System register [DBGDTRTX_ELO](#).

AArch32 System register DBGDTRTXint is architecturally mapped to External register [DBGDTRTX_ELO](#).

This register is in the Cold reset domain. On a Cold reset RW fields in this register reset to architecturally UNKNOWN values. The register is not affected by a Warm reset.

Attributes

DBGDTRTXint is a 32-bit register.

Field descriptions

The DBGDTRTXint bit assignments are:

Bits [31:0]

Return DTRTX.

If TXfull is set to 0, then writes of this register update the value in DTRTX and set TXfull to 1.

For the full behavior of the Debug Communications Channel, see [Chapter H4 The Debug Communication Channel and Instruction Transfer Register](#).

This field resets to a value that is architecturally UNKNOWN.

Accessing the DBGDTRTXint

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p14, 0, <Rt>, c0, c5, 0	000	000	0000	1110	0101

Data can be loaded from memory into this register using [LDC \(immediate\)](#) and [LDC \(literal\)](#).

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	WO	WO	n/a	WO
x	0	1	WO	WO	WO	WO
x	1	1	WO	n/a	WO	WO

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules, in Non-debug state:

- In both security states, and not dependent on other bits:
 - If `DBGDSCRExt.UDCCdis==1`, write accesses to this register from EL0 are trapped to Undefined mode.
 - If `MDSCR_EL1.TDCC==1`, write accesses to this register from EL0 are trapped to EL1.
- When EL2 is implemented and is using AArch64 and `SCR_EL3.NS == 1`:
 - If `MDCR_EL2.TDA==1`, Non-secure write accesses to this register from EL0 and EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and `SCR_EL3.NS == 1`:
 - If `HDCR.TDA==1`, Non-secure write accesses to this register from EL0 and EL1 are trapped to Hyp mode.
- When EL3 is implemented and is using AArch64:
 - If `MDCR_EL3.TDA==1`, write accesses to this register from EL0, EL1, and EL2 are trapped to EL3.

———— **Note** —————

Write accesses to this register are not trapped in Debug state.

G6.3.20 DBGOSDLR, Debug OS Double Lock Register

The DBGOSDLR characteristics are:

Purpose

Locks out the external debug interface.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register DBGOSDLR is architecturally mapped to AArch64 System register [OSDLR_EL1](#).

This register is in the Warm reset domain. Some or all RW fields of this register have defined reset values. On a Warm or Cold reset these apply only if the PE resets into an Exception level that is using AArch32. Otherwise, on a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

DBGOSDLR is a 32-bit register.

Field descriptions

The DBGOSDLR bit assignments are:

Bits [31:1]

Reserved, RES0.

DLK, bit [0]

OS Double Lock control bit. Possible values are:

- 0 OS Double Lock unlocked.
- 1 OS Double Lock locked, if [DBGPRCR.CORENPDRQ](#) (Core no powerdown request) bit is set to 0 and the PE is in Non-debug state.

When this register has an architecturally-defined reset value, this field resets to 0.

Accessing the DBGOSDLR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p14, 0, <Rt>, c1, c3, 4	000	100	0001	1110	0011

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	RW	n/a	RW
x	0	1	-	RW	RW	RW
x	1	1	-	n/a	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state](#) on page G1-4344 for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64](#) on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and SCR_EL3.NS == 1:
 - If MDCR_EL2.TDOSA==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HDCR.TDOSA==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
- When EL3 is implemented and is using AArch64:
 - If MDCR_EL3.TDOSA==1, accesses to this register from EL1 and EL2 are trapped to EL3.

G6.3.21 DBGOSECCR, Debug OS Lock Exception Catch Control Register

The DBGOSECCR characteristics are:

Purpose

Provides a mechanism for an operating system to access the contents of [EDECCR](#) that are otherwise invisible to software, so it can save/restore the contents of [EDECCR](#) over powerdown on behalf of the external debugger.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register DBGOSECCR is architecturally mapped to AArch64 System register [OSECCR_EL1](#).

AArch32 System register DBGOSECCR is architecturally mapped to External register [EDECCR](#).

If `OSLSR.OSLK == 0` then DBGOSECCR returns an UNKNOWN value on reads and ignores writes.

Attributes

DBGOSECCR is a 32-bit register.

Field descriptions

The DBGOSECCR bit assignments are:

When `OSLSR.OSLK==1`:

EDECCR, bits [31:0]

Used for save/restore to [EDECCR](#) over powerdown.

Reads or writes to this field are indirect accesses to [EDECCR](#).

Accessing the DBGOSECCR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p14, 0, <Rt>, c0, c6, 2	000	010	0000	1110	0110

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	RW	n/a	RW
x	0	1	-	RW	RW	RW
x	1	1	-	n/a	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state](#) on page G1-4344 for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64](#) on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and SCR_EL3.NS == 1:
 - If MDCR_EL2.TDA==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HDCR.TDA==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
- When EL3 is implemented and is using AArch64:
 - If MDCR_EL3.TDA==1, accesses to this register from EL1 and EL2 are trapped to EL3.

G6.3.22 DBGOSLAR, Debug OS Lock Access Register

The DBGOSLAR characteristics are:

Purpose

Provides a lock for the debug registers. The OS lock also disables some Software debug events.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register DBGOSLAR is architecturally mapped to AArch64 System register [OSLAR_EL1](#).

AArch32 System register DBGOSLAR is architecturally mapped to External register [OSLAR_EL1](#).

Attributes

DBGOSLAR is a 32-bit register.

Field descriptions

The DBGOSLAR bit assignments are:

Bits [31:0]

OS Lock Access. Writing the value 0xC5ACCE55 to the DBGOSLAR sets the OS lock to 1. Writing any other value sets the OS lock to 0.

Use [DBGOSLSR.OSLK](#) to check the current status of the lock.

Accessing the DBGOSLAR

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p14, 0, <Rt>, c1, c0, 4	000	100	0001	1110	0000

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	WO	n/a	WO
x	0	1	-	WO	WO	WO
x	1	1	-	n/a	WO	WO

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and SCR_EL3.NS == 1:
 - If MDCR_EL2.TDOSA==1, Non-secure write accesses to this register from EL1 are trapped to EL2 using AArch64.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HDCR.TDOSA==1, Non-secure write accesses to this register from EL1 are trapped to Hyp mode.
- When EL3 is implemented and is using AArch64:
 - If MDCR_EL3.TDOSA==1, write accesses to this register from EL1 and EL2 are trapped to EL3 using AArch64.

G6.3.23 DBGOSLSR, Debug OS Lock Status Register

The DBGOSLSR characteristics are:

Purpose

Provides status information for the OS lock.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register DBGOSLSR is architecturally mapped to AArch64 System register [OSLSR_EL1](#).

The OS lock status is also visible in the external debug interface through EDPRSR.

This register is in the Cold reset domain. Some or all RW fields of this register have defined reset values. On a Cold reset these apply only if the PE resets into an Exception level that is using AArch32. Otherwise, on a Cold reset RW fields in this register reset to architecturally UNKNOWN values. The register is not affected by a Warm reset.

Attributes

DBGOSLSR is a 32-bit register.

Field descriptions

The DBGOSLSR bit assignments are:

Bits [31:4]

Reserved, RES0.

OSLM[1], bit [3]

See below for description of the OSLM field.

nTT, bit [2]

Not 32-bit access. This bit is always RAZ. It indicates that a 32-bit access is needed to write the key to the OS Lock Access Register.

OSLK, bit [1]

OS Lock Status. The possible values are:

- 0 OS lock unlocked.
- 1 OS lock locked.

The OS lock is locked and unlocked by writing to the OS Lock Access Register.

When this register has an architecturally-defined reset value, this field resets to 1.

OSLM[0], bit [0]

OS lock model implemented. Identifies the form of OS save and restore mechanism implemented. In ARMv8 these bits are as follows:

10 OS lock implemented. DBGOSSRR not implemented.

All other values are reserved.

Accessing the DBGOSLSR

This register can be read using MRC with the following syntax:

MRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p14, 0, <Rt>, c1, c1, 4	000	100	0001	1110	0001

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	RO	n/a	RO
x	0	1	-	RO	RO	RO
x	1	1	-	n/a	RO	RO

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and SCR_EL3.NS == 1:
 - If MDCR_EL2.TDOSA==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HDCR.TDOSA==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
- When EL3 is implemented and is using AArch64:
 - If MDCR_EL3.TDOSA==1, read accesses to this register from EL1 and EL2 are trapped to EL3.

G6.3.24 DBGPRCR, Debug Power Control Register

The DBGPRCR characteristics are:

Purpose

Controls behavior of the PE on powerdown request.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register DBGPRCR is architecturally mapped to AArch64 System register [DBGPRCR_EL1](#).

Bit [0] of this register is mapped to [EDPRCR.CORENPDRQ](#), bit [0] of the external view of this register.

The other bits in these registers are not mapped to each other.

This register is in the Cold reset domain. On a Cold reset RW fields in this register reset to architecturally UNKNOWN values. The register is not affected by a Warm reset.

Attributes

DBGPRCR is a 32-bit register.

Field descriptions

The DBGPRCR bit assignments are:

Bits [31:1]

Reserved, RES0.

CORENPDRQ, bit [0]

Core no powerdown request. Requests emulation of powerdown. Possible values of this bit are:

- 0 If the system responds to a powerdown request, it powers down Core power domain.
- 1 If the system responds to a powerdown request, it does not powerdown the Core power domain, but instead emulates a powerdown of that domain.

Writes to this bit are permitted regardless of the state of the IMPLEMENTATION DEFINED authentication interface. This means that a debugger can request Core no powerdown regardless of whether invasive debug is permitted.

It is IMPLEMENTATION DEFINED whether this bit is reset to the value of [EDPRCR.COREPURQ](#) on exit from an IMPLEMENTATION DEFINED software-visible retention state.

Accessing the DBGPRCR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p14, 0, <Rt>, c1, c4, 4	000	100	0001	1110	0100

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	RW	n/a	RW
x	0	1	-	RW	RW	RW
x	1	1	-	n/a	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and SCR_EL3.NS == 1:
 - If MDCR_EL2.TDOSA==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HDCR.TDOSA==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
- When EL3 is implemented and is using AArch64:
 - If MDCR_EL3.TDOSA==1, accesses to this register from EL1 and EL2 are trapped to EL3.

G6.3.25 DBGVCR, Debug Vector Catch Register

The DBGVCR characteristics are:

Purpose

Controls Vector Catch debug events.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register DBGVCR is architecturally mapped to AArch64 System register [DBGVCR32_EL2](#).

This register is required in all implementations.

This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

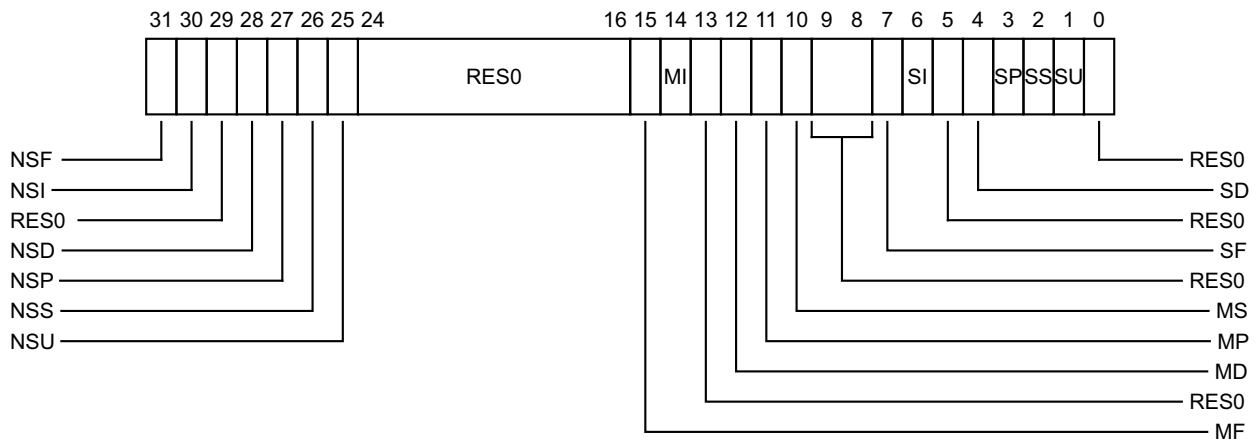

Attributes

DBGVCR is a 32-bit register.

Field descriptions

The DBGVCR bit assignments are:

When EL3 implemented and using AArch32:

NSF, bit [31]

FIQ vector catch enable in Non-secure state.

The exception vector offset is 0x1C.

This field resets to a value that is architecturally UNKNOWN.

NSI, bit [30]

IRQ vector catch enable in Non-secure state.

The exception vector offset is 0x18.

This field resets to a value that is architecturally UNKNOWN.

Bit [29]

Reserved, RES0.

NSD, bit [28]

Data Abort vector catch enable in Non-secure state.

The exception vector offset is $0x10$.
This field resets to a value that is architecturally UNKNOWN.

NSP, bit [27]

Prefetch Abort vector catch enable in Non-secure state.
The exception vector offset is $0x0C$.
This field resets to a value that is architecturally UNKNOWN.

NSS, bit [26]

Supervisor Call (SVC) vector catch enable in Non-secure state.
The exception vector offset is $0x08$.
This field resets to a value that is architecturally UNKNOWN.

NSU, bit [25]

Undefined Instruction vector catch enable in Non-secure state.
The exception vector offset is $0x04$.
This field resets to a value that is architecturally UNKNOWN.

Bits [24:16]

Reserved, RES0.

MF, bit [15]

FIQ vector catch enable in Monitor mode.
The exception vector offset is $0x1C$.
This field resets to a value that is architecturally UNKNOWN.

MI, bit [14]

IRQ vector catch enable in Monitor mode.
The exception vector offset is $0x18$.
This field resets to a value that is architecturally UNKNOWN.

Bit [13]

Reserved, RES0.

MD, bit [12]

Data Abort vector catch enable in Monitor mode.
The exception vector offset is $0x10$.
This field resets to a value that is architecturally UNKNOWN.

MP, bit [11]

Prefetch Abort vector catch enable in Monitor mode.
The exception vector offset is $0x0C$.
This field resets to a value that is architecturally UNKNOWN.

MS, bit [10]

Secure Monitor Call (SMC) vector catch enable in Monitor mode.
The exception vector offset is $0x08$.
This field resets to a value that is architecturally UNKNOWN.

Bits [9:8]

Reserved, RES0.

SF, bit [7]

FIQ vector catch enable in Secure state.
 The exception vector offset is 0x1C.
 This field resets to a value that is architecturally UNKNOWN.

SI, bit [6]

IRQ vector catch enable in Secure state.
 The exception vector offset is 0x18.
 This field resets to a value that is architecturally UNKNOWN.

Bit [5]

Reserved, RES0.

SD, bit [4]

Data Abort vector catch enable in Secure state.
 The exception vector offset is 0x10.
 This field resets to a value that is architecturally UNKNOWN.

SP, bit [3]

Prefetch Abort vector catch enable in Secure state.
 The exception vector offset is 0x0C.
 This field resets to a value that is architecturally UNKNOWN.

SS, bit [2]

Supervisor Call (SVC) vector catch enable in Secure state.
 The exception vector offset is 0x08.
 This field resets to a value that is architecturally UNKNOWN.

SU, bit [1]

Undefined Instruction vector catch enable in Secure state.
 The exception vector offset is 0x04.
 This field resets to a value that is architecturally UNKNOWN.

Bit [0]

Reserved, RES0.

When EL3 implemented and using AArch64:

NSF, bit [31]

FIQ vector catch enable in Non-secure state.
The exception vector offset is 0x1C.
This field resets to a value that is architecturally UNKNOWN.

NSI, bit [30]

IRQ vector catch enable in Non-secure state.
The exception vector offset is 0x18.
This field resets to a value that is architecturally UNKNOWN.

Bit [29]

Reserved, RES0.

NSD, bit [28]

Data Abort vector catch enable in Non-secure state.
The exception vector offset is 0x10.
This field resets to a value that is architecturally UNKNOWN.

NSP, bit [27]

Prefetch Abort vector catch enable in Non-secure state.
The exception vector offset is 0x0C.
This field resets to a value that is architecturally UNKNOWN.

NSS, bit [26]

Supervisor Call (SVC) vector catch enable in Non-secure state.
The exception vector offset is 0x08.
This field resets to a value that is architecturally UNKNOWN.

NSU, bit [25]

Undefined Instruction vector catch enable in Non-secure state.
The exception vector offset is 0x04.
This field resets to a value that is architecturally UNKNOWN.

Bits [24:8]

Reserved, RES0.

SF, bit [7]

FIQ vector catch enable in Secure state.
The exception vector offset is 0x1C.
This field resets to a value that is architecturally UNKNOWN.

SI, bit [6]

IRQ vector catch enable in Secure state.
The exception vector offset is 0x18.
This field resets to a value that is architecturally UNKNOWN.

Bit [5]

Reserved, RES0.

SD, bit [4]

Data Abort vector catch enable in Secure state.
The exception vector offset is 0x10.

This field resets to a value that is architecturally UNKNOWN.

SP, bit [3]

Prefetch Abort vector catch enable in Secure state.

The exception vector offset is 0x0C.

This field resets to a value that is architecturally UNKNOWN.

SS, bit [2]

Supervisor Call (SVC) vector catch enable in Secure state.

The exception vector offset is 0x08.

This field resets to a value that is architecturally UNKNOWN.

SU, bit [1]

Undefined Instruction vector catch enable in Secure state.

The exception vector offset is 0x04.

This field resets to a value that is architecturally UNKNOWN.

Bit [0]

Reserved, RES0.

When EL3 not implemented:

Bits [31:8]

Reserved, RES0.

F, bit [7]

FIQ vector catch enable.

The exception vector offset is 0x1C.

This field resets to a value that is architecturally UNKNOWN.

I, bit [6]

IRQ vector catch enable.

The exception vector offset is 0x18.

This field resets to a value that is architecturally UNKNOWN.

Bit [5]

Reserved, RES0.

D, bit [4]

Data Abort vector catch enable.

The exception vector offset is 0x10.

This field resets to a value that is architecturally UNKNOWN.

P, bit [3]

Prefetch Abort vector catch enable.

The exception vector offset 0x0C.
This field resets to a value that is architecturally UNKNOWN.

S, bit [2]

Supervisor Call (SVC) vector catch enable.
The exception vector offset is 0x08.
This field resets to a value that is architecturally UNKNOWN.

U, bit [1]

Undefined Instruction vector catch enable.
The exception vector offset is 0x04.
This field resets to a value that is architecturally UNKNOWN.

Bit [0]

Reserved, RES0.

Accessing the DBGVCR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p14, 0, <Rt>, c0, c7, 0	000	000	0000	1110	0111

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	RW	n/a	RW
x	0	1	-	RW	RW	RW
x	1	1	-	n/a	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and SCR_EL3.NS == 1:
 - If MDCR_EL2.TDA==1, Non-secure accesses to this register from EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If [HDCR.TDA](#)==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
- When EL3 is implemented and is using AArch64:
 - If [MDCR_EL3.TDA](#)==1, accesses to this register from EL1 and EL2 are trapped to EL3.

G6.3.26 DBGWCR<n>, Debug Watchpoint Control Registers, n = 0 - 15

The DBGWCR<n> characteristics are:

Purpose

Holds control information for a watchpoint. Forms watchpoint n together with value register [DBGWVR<n>](#).

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register DBGWCR<n> is architecturally mapped to AArch64 System register [DBGWCR<n>_EL1](#).

AArch32 System register DBGWCR<n> is architecturally mapped to External register [DBGWCR<n>_EL1](#).

If breakpoint n is not implemented then this register is unallocated.

This register is in the Cold reset domain. On a Cold reset RW fields in this register reset to architecturally UNKNOWN values. The register is not affected by a Warm reset.

Attributes

DBGWCR<n> is a 32-bit register.

Field descriptions

The DBGWCR<n> bit assignments are:

When the E field is zero, all the other fields in the register are ignored.

Bits [31:29]

Reserved, RES0.

MASK, bits [28:24]

Address mask. Only objects up to 2GB can be watched using a single mask.

00000	No mask.
00001	Reserved.
00010	Reserved.

If programmed with a reserved value, a watchpoint must behave as if either:

- MASK has been programmed with a defined value, which might be 0 (no mask), other than for a direct read of [DBGWCRn_EL1](#).
- The watchpoint is disabled.

Software must not rely on this property because the behavior of reserved values might change in a future revision of the architecture.

Other values mask the corresponding number of address bits, from 0b00011 masking 3 address bits (0x00000007 mask for address) to 0b11111 masking 31 address bits (0xFFFFFFFF mask for address).

This field resets to a value that is architecturally UNKNOWN.

Bits [23:21]

Reserved, RES0.

WT, bit [20]

Watchpoint type. Possible values are:

- 0 Unlinked data address match.
- 1 Linked data address match.

This field resets to a value that is architecturally UNKNOWN.

LBN, bits [19:16]

Linked breakpoint number. For Linked data address watchpoints, this specifies the index of the Context-matching breakpoint linked to.

This field resets to a value that is architecturally UNKNOWN.

SSC, bits [15:14]

Security state control. Determines the Security states under which a Watchpoint debug event for watchpoint n is generated. This field must be interpreted along with the HMC and PAC fields.

For more information on the operation of the SSC, HMC, and PAC fields, see [Execution conditions for which a watchpoint generates Watchpoint exceptions on page G2-4499](#).

This field resets to a value that is architecturally UNKNOWN.

HMC, bit [13]

Higher mode control. Determines the debug perspective for deciding when a Watchpoint debug event for watchpoint n is generated. This field must be interpreted along with the SSC and PAC fields.

For more information on the operation of the SSC, HMC, and PAC fields, see [Execution conditions for which a watchpoint generates Watchpoint exceptions on page G2-4499](#).

This field resets to a value that is architecturally UNKNOWN.

BAS, bits [12:5]

Byte address select. Each bit of this field selects whether a byte from within the word or double-word addressed by `DBGWVR<n>` is being watched.

BAS	Description
xxxxxxx1	Match byte at <code>DBGWVR<n></code>
xxxxxx1x	Match byte at <code>DBGWVR<n>+1</code>
xxxxx1xx	Match byte at <code>DBGWVR<n>+2</code>
xxxx1xxx	Match byte at <code>DBGWVR<n>+3</code>

In cases where `DBGWVR<n>` addresses a double-word:

BAS	Description, if <code>DBGWVR<n>[2] == 0</code>
xxx1xxxx	Match byte at <code>DBGWVR<n>+4</code>
xx1xxxxx	Match byte at <code>DBGWVR<n>+5</code>
x1xxxxxx	Match byte at <code>DBGWVR<n>+6</code>
1xxxxxxx	Match byte at <code>DBGWVR<n>+7</code>

If `DBGWVR<n>[2] == 1`, only `BAS[3:0]` are used and `BAS[7:4]` are ignored. ARM deprecates setting `DBGWVR<n>[2] == 1`.

The valid values for `BAS` are non-zero binary numbers all of whose set bits are contiguous. All other values are reserved and must not be used by software. See [Reserved `DBGWCR<n>.BAS` values on page G2-4507](#)

This field resets to a value that is architecturally UNKNOWN.

LSC, bits [4:3]

Load/store control. This field enables watchpoint matching on the type of access being made. Possible values of this field are:

- 01 Match instructions that load from a watchpointed address.
- 10 Match instructions that store to a watchpointed address.
- 11 Match instructions that load from or store to a watchpointed address.

All other values are reserved, but must behave as if the watchpoint is disabled. Software must not rely on this property as the behavior of reserved values might change in a future revision of the architecture.

This field resets to a value that is architecturally UNKNOWN.

PAC, bits [2:1]

Privilege of access control. Determines the Exception level or levels at which a Watchpoint debug event for watchpoint `n` is generated. This field must be interpreted along with the `SSC` and `HMC` fields.

For more information on the operation of the `SSC`, `HMC`, and `PAC` fields, see [Execution conditions for which a watchpoint generates Watchpoint exceptions on page G2-4499](#).

This field resets to a value that is architecturally UNKNOWN.

E, bit [0]

Enable watchpoint `n`. Possible values are:

- 0 Watchpoint disabled.
- 1 Watchpoint enabled.

This field resets to a value that is architecturally UNKNOWN.

Accessing the `DBGWCR<n>`

This register can be read using `MRC` with the following syntax:

`MRC <syntax>`

This register can be written using `MCR` with the following syntax:

`MCR <syntax>`

This syntax is encoded with the following settings in the instruction encoding:

<code><syntax></code>	<code>opc1</code>	<code>opc2</code>	<code>CRn</code>	<code>coproc</code>	<code>CRm</code>
<code>p14, 0, <Rt>, c0, <CRm>, 7</code>	000	111	0000	1110	<code>n<3:0></code>

- `<CRm>` is in the range `c0 - c15`.

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	RW	n/a	RW
x	0	1	-	RW	RW	RW
x	1	1	-	n/a	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see:

- [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state.
- [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state.
- [Software Access debug event on page H3-5493](#) for accesses to this register taken to Debug state.

Subject to the prioritization rules:

- In both security states, and not dependent on other bits:
 - If `EDSCR.TDA==1`, `DBGOSLSR.OSLK==0`, and halting is allowed, accesses to this register from EL1 and EL2 generate a Software Access debug event.
- When EL2 is implemented and is using AArch64 and `SCR_EL3.NS == 1`:
 - If `MDCR_EL2.TDA==1`, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and `SCR_EL3.NS == 1`:
 - If `HDCR.TDA==1`, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
- When EL3 is implemented and is using AArch64:
 - If `MDCR_EL3.TDA==1`, accesses to this register from EL1 and EL2 are trapped to EL3.

G6.3.27 DBGWFAR, Debug Watchpoint Fault Address Register

The DBGWFAR characteristics are:

Purpose

Previously returned information about the address of the instruction that accessed a watchpointed address. Is now deprecated and RES0.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

Attributes

DBGWFAR is a 32-bit register.

Field descriptions

The DBGWFAR bit assignments are:

Bits [31:0]

Reserved, RES0.

Accessing the DBGWFAR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p14, 0, <Rt>, c0, c6, 0	000	000	0000	1110	0110

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	RW	n/a	RW
x	0	1	-	RW	RW	RW
x	1	1	-	n/a	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and $SCR_EL3.NS == 1$:
 - If $MDCR_EL2.TDA == 1$, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $HDCR.TDA == 1$, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
- When EL3 is implemented and is using AArch64:
 - If $MDCR_EL3.TDA == 1$, accesses to this register from EL1 and EL2 are trapped to EL3.

G6.3.28 DBGWVR<n>, Debug Watchpoint Value Registers, n = 0 - 15

The DBGWVR<n> characteristics are:

Purpose

Holds a data address value for use in watchpoint matching. Forms watchpoint n together with control register [DBGWCR<n>](#).

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register DBGWVR<n> is architecturally mapped to AArch64 System register [DBGWVR<n>_EL1](#)[31:0].

AArch32 System register DBGWVR<n> is architecturally mapped to External register [DBGWVR<n>_EL1](#)[31:0].

If breakpoint n is not implemented then this register is unallocated.

This register is in the Cold reset domain. On a Cold reset RW fields in this register reset to architecturally UNKNOWN values. The register is not affected by a Warm reset.

Attributes

DBGWVR<n> is a 32-bit register.

Field descriptions

The DBGWVR<n> bit assignments are:

VA, bits [31:2]

Bits[31:2] of the address value for comparison.

ARM deprecates setting [DBGWVR<n>](#)[2] == 1.

This field resets to a value that is architecturally UNKNOWN.

Bits [1:0]

Reserved, RES0.

Accessing the DBGWVR<n>

This register can be read using MRC with the following syntax:

```
MRC <syntax>
```

This register can be written using MCR with the following syntax:

```
MCR <syntax>
```

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p14, 0, <Rt>, c0, <CRm>, 6	000	110	0000	1110	n<3:0>

- <CRm> is in the range c0 - c15.

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	RW	n/a	RW
x	0	1	-	RW	RW	RW
x	1	1	-	n/a	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see:

- [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state.
- [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state.
- [Software Access debug event on page H3-5493](#) for accesses to this register taken to Debug state.

Subject to the prioritization rules:

- In both security states, and not dependent on other bits:
 - If `EDSCR.TDA==1`, `DBGOSLSR.OSLK==0`, and halting is allowed, accesses to this register from EL1 and EL2 generate a Software Access debug event.
- When EL2 is implemented and is using AArch64 and `SCR_EL3.NS == 1`:
 - If `MDCR_EL2.TDA==1`, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL3 is implemented and is using AArch64:
 - If `MDCR_EL3.TDA==1`, accesses to this register from EL1 and EL2 are trapped to EL3.

G6.3.29 DLR, Debug Link Register

The DLR characteristics are:

Purpose

In Debug state, holds the address to restart from.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states. AArch32 System register DLR is architecturally mapped to AArch64 System register [DLR_EL0](#)[31:0].

Attributes

DLR is a 32-bit register.

Field descriptions

The DLR bit assignments are:

Bits [31:0]

Restart address.

Accessing the DLR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 3, <Rt>, c4, c5, 1	011	001	0100	1111	0101

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	RW	RW	n/a	RW
x	0	1	RW	RW	RW	RW
x	1	1	RW	n/a	RW	RW

Access to this register is from Debug state only. During normal execution this register is unallocated.

G6.3.30 DSPSR, Debug Saved Program Status Register

The DSPSR characteristics are:

Purpose

Holds the saved process state on entry to Debug state.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register DSPSR is architecturally mapped to AArch64 System register [DSPSR_EL0](#).

Attributes

DSPSR is a 32-bit register.

Field descriptions

The DSPSR bit assignments are:

When entering Debug state from AArch32 and exiting Debug state to AArch32:

N, bit [31]

Set to the value of [CPSR.N](#) on entering Debug state, and copied to [CPSR.N](#) on exiting Debug state.

Z, bit [30]

Set to the value of [CPSR.Z](#) on entering Debug state, and copied to [CPSR.Z](#) on exiting Debug state.

C, bit [29]

Set to the value of [CPSR.C](#) on entering Debug state, and copied to [CPSR.C](#) on exiting Debug state.

V, bit [28]

Set to the value of [CPSR.V](#) on entering Debug state, and copied to [CPSR.V](#) on exiting Debug state.

Q, bit [27]

Set to the value of [CPSR.Q](#) on entering Debug state, and copied to [CPSR.Q](#) on exiting Debug state.

IT[1:0], bits [26:25]

IT block state bits for the T32 IT (If-Then) instruction. See [IT\[7:2\]](#) for explanation of this field.

J, bit [24]

RES0.

In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state. ARMv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

Bit [23]

Reserved, RES0.

PAN, bit [22]

In ARMv8.2 and ARMv8.1

When **ARMv8.1-PAN** is implemented, set to the value of **CPSR.PAN** on entering Debug state, and copied to **CPSR.PAN** on exiting Debug state.

When **ARMv8.1-PAN** is not implemented, this bit is RES0.

In ARMv8.0.

Reserved, RES0.

SS, bit [21]

Software step. Shows the value of **PSTATE.SS** immediately before Debug state was entered.

IL, bit [20]

Illegal Execution state bit. Shows the value of **PSTATE.IL** immediately before Debug state was entered.

GE, bits [19:16]

Greater than or Equal flags, for parallel addition and subtraction.

IT[7:2], bits [15:10]

IT block state bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

- **IT[7:5]** holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- **IT[4:0]** encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is **0b00000000** when no IT block is active.

E, bit [9]

Endianness state bit. Controls the load and store endianness for data accesses:

- | | |
|---|-------------------------|
| 0 | Little-endian operation |
| 1 | Big-endian operation. |

Instruction fetches ignore this bit.

When the reset value of the **SCTLR.EE** bit is defined by a configuration input signal, that value also applies to the **CPSR.E** bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any Exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any Exception level other than EL0.

A, bit [8]

SError interrupt mask bit. The possible values of this bit are:

- | | |
|---|-----------------------|
| 0 | Exception not masked. |
| 1 | Exception masked. |

I, bit [7]

IRQ mask bit. The possible values of this bit are:

- | | |
|---|-----------------------|
| 0 | Exception not masked. |
| 1 | Exception masked. |

F, bit [6]

FIQ mask bit. The possible values of this bit are:

- 0 Exception not masked.
- 1 Exception masked.

T, bit [5]

T32 Instruction set state bit. Determines the AArch32 instruction set state that the Debug state entry was taken from. Possible values of this bit are:

- 0 Taken from A32 state.
- 1 Taken from T32 state.

M[4], bit [4]

Execution state that Debug state was entered from. Possible values of this bit are:

- 1 Exception taken from AArch32.

M[3:0], bits [3:0]

AArch32 mode that Debug state was entered from. The possible values are:

M[3:0]	Mode
0b0000	User
0b0001	FIQ
0b0010	IRQ
0b0011	Supervisor
0b0110	Monitor (only valid in Secure state, if EL3 is implemented and can use AArch32)
0b0111	Abort
0b1010	Hyp
0b1011	Undefined
0b1111	System

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is CONstrained UNPREDICTABLE, as described in *Reserved values in System and memory-mapped registers and translation table entries* on page K1-6117.

Accessing the DSPSR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 3, <Rt>, c4, c5, 0	011	000	0100	1111	0101

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	RW	RW	n/a	RW
x	0	1	RW	RW	RW	RW
x	1	1	RW	n/a	RW	RW

Access to this register is from Debug state only. During normal execution this register is unallocated.

G6.3.31 HDCR, Hyp Debug Control Register

The HDCR characteristics are:

Purpose

Controls the trapping to Hyp mode of Non-secure accesses, at EL1 or lower, to functions provided by the debug and trace architectures and the Performance Monitors Extension.

Configurations

AArch32 System register HDCR is architecturally mapped to AArch64 System register [MDCR_EL2](#).

If EL2 is not implemented, this register is RES0 from EL3.

This register is in the Warm reset domain. Some or all RW fields of this register have defined reset values. On a Warm or Cold reset these apply only if the PE resets into an Exception level that is using AArch32. Otherwise, on a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

HDCR is a 32-bit register.

Field descriptions

The HDCR bit assignments are:

Bits [31:18]

Reserved, RES0.

HPMD, bit [17]

In ARMv8.2 and ARMv8.1

Guest Performance Monitors Disable. This control prohibits event counting at EL2. Permitted values are:

- 0 Event counting allowed in Hyp mode.
- 1 Event counting prohibited in Hyp mode.

In an ARMv8.1 implementation, event counting is prohibited unless enabled by the IMPLEMENTATION DEFINED authentication interface `ExternalSecureNoninvasiveDebugEnabled()`.

This control applies only to:

- The event counters in the range `[0..(HPMN-1)]`.
- If `PMCR.DP` is set to 1, `PMCCNTR`.

The other event counters are unaffected. When `PMCR.DP` is set to 0, `PMCCNTR` is unaffected.

When this register has an architecturally-defined reset value, this field resets to 0.

In ARMv8.0.

Reserved, RES0.

Bits [16:12]

Reserved, RES0.

TDRA, bit [11]

Trap Debug ROM Address register access. Traps Non-secure EL0 and EL1 System register accesses to the Debug ROM registers to Hyp mode.

0 This control does not cause any instructions to be trapped.

1 Non-secure EL0 and EL1 System register accesses to the [DBGDRAR](#) or [DBGDSAR](#) are trapped to Hyp mode, unless it is trapped by [DBGDSCRExt.UDCCdis](#).

If [HCR.TGE](#) or [HDCR.TDE](#) is 1, behavior is as if this bit is 1 other than for the purpose of a direct read.

When this register has an architecturally-defined reset value, this field resets to 0.

TDOSA, bit [10]

Trap debug OS-related register access. Traps Non-secure EL1 System register accesses to the powerdown debug registers to Hyp mode.

0 This control does not cause any instructions to be trapped.

1 Non-secure EL1 System register accesses to the powerdown debug registers are trapped to Hyp mode.

The registers for which accesses are trapped are as follows:

- [DBGOSLSR](#), [DBGOSLAR](#), [DBGOSDLR](#), and the [DBGPRCR](#).
- Any IMPLEMENTATION DEFINED register with similar functionality that the implementation specifies as trapped by this bit.

———— **Note** ————

These registers are not accessible at EL0.

If [HCR.TGE](#) or [HDCR.TDE](#) is 1, behavior is as if this bit is 1 other than for the purpose of a direct read.

When this register has an architecturally-defined reset value, this field resets to 0.

TDA, bit [9]

Trap debug access. Traps Non-secure EL0 and EL1 System register accesses to those debug System registers in the (coproc==1110) encoding space that are not trapped by either of the following:

- [HDCR.TDRA](#).
- [HDCR.TDOSA](#).

0 This control does not cause any instructions to be trapped.

1 Non-secure EL0 or EL1 System register accesses to the debug registers, other than the registers trapped by [HDCR.TDRA](#) and [HDCR.TDOSA](#), are trapped to Hyp mode, unless it is trapped by [DBGDSCRExt.UDCCdis](#).

Traps of AArch32 accesses to [DBGDTRRXint](#) and [DBGDTRTXint](#) are ignored in Debug state.

If [HCR.TGE](#) or [HDCR.TDE](#) is 1, behavior is as if this bit is 1 other than for the purpose of a direct read.

When this register has an architecturally-defined reset value, this field resets to 0.

TDE, bit [8]

Trap Debug exceptions. The possible values of this bit are:

0 This control has no effect on the routing of debug exceptions, and has no effect on Non-secure accesses to debug registers.

- 1 In Non-secure state:
- Debug exceptions generated at EL1 or EL0 are routed to EL2.
 - The HDCR.{TDRA, TDOSA, TDA} fields are treated as being 1 for all purposes other than returning the result of a direct read of the register.

When `HCR.TGE == 1`, the PE behaves as if the value of this field is 1 for all purposes other than returning the value of a direct read of the register.

When this register has an architecturally-defined reset value, this field resets to 0.

HPME, bit [7]

Hypervisor Performance Monitors Counters Enable. The possible values of this bit are:

- 0 Hyp mode Performance Monitors counters disabled.
- 1 Hyp mode Performance Monitors counters enabled.

When the value of this bit is 1, the Performance Monitors counters that are reserved for use from Hyp mode or Secure state are enabled. For more information see the description of the HPMN field.

If the Performance Monitors Extension is not implemented, this field is RES0.

If this field is implemented as an RW field, it resets to a value that is architecturally UNKNOWN.

TPM, bit [6]

Trap Performance Monitors accesses. Traps Non-secure EL0 and EL1 accesses to all Performance Monitors registers to Hyp mode.

- 0 This control does not cause any instructions to be trapped.
- 1 Non-secure EL0 and EL1 accesses to all Performance Monitors registers are trapped to Hyp mode.

———— Note —————

EL2 does not provide traps on Performance Monitor register accesses through the optional memory-mapped external debug interface.

If the Performance Monitors Extension is not implemented, this field is RES0.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to 0.

TPMCR, bit [5]

Trap `PMCR` accesses. Traps Non-secure EL0 and EL1 accesses to the `PMCR` to Hyp mode.

- 0 This control does not cause any instructions to be trapped.
- 1 Non-secure EL0 and EL1 accesses to the `PMCR` are trapped to Hyp mode, unless it is trapped by `PMUSERENR.EN`.

———— Note —————

EL2 does not provide traps on Performance Monitor register accesses through the optional memory-mapped external debug interface.

If the Performance Monitors Extension is not implemented, this field is RES0.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to 0.

HPMN, bits [4:0]

Defines the number of Performance Monitors counters that are accessible from Non-secure EL1 modes, and from Non-secure EL0 modes if unprivileged access is enabled.

If the Performance Monitors Extension is not implemented, this field is RES0.

In Non-secure state, HPMN divides the Performance Monitors counters as follows. If software is accessing Performance Monitors counter n then, in Non-secure state:

- If n is in the range $0 \leq n < \text{HPMN}$, the counter is accessible from EL1 and EL2, and from EL0 if unprivileged access to the counters is enabled. **PMCR.E** enables the operation of counters in this range.
- If n is in the range $\text{HPMN} \leq n < \text{PMCR.N}$, the counter is accessible only from EL2 and from Secure state. **HDCR.HPME** enables the operation of counters in this range.

If this field is set to 0, or to a value larger than **PMCR.N**, then the following **CONSTRAINED UNPREDICTABLE** behavior applies:

- The value returned by a direct read of **HDCR.HPMN** is **UNKNOWN**.
- Either:
 - An **UNKNOWN** number of counters are reserved for EL2 use. That is, the PE behaves as if **HDCR.HPMN** is set to an **UNKNOWN** non-zero value less than **PMCR.N**.
 - All counters are reserved for EL2 use, meaning no counters are accessible from Non-secure EL1 and Non-secure EL0.

When this register has an architecturally-defined reset value, if this field is implemented as an **RW** field, it resets to the value of **PMCR.N**.

Accessing the HDCR

This register can be read using **MRC** with the following syntax:

MRC <syntax>

This register can be written using **MCR** with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 4, <Rt>, c1, c1, 1	100	001	0001	1111	0001

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	-
x	0	1	-	-	RW	RW
x	1	1	-	n/a	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If HSTR_EL2.T1==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If HSTR_EL2.T1==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HSTR.T1==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
- When EL3 is implemented and is using AArch64:
 - If MDCR_EL3.TDA==1, accesses to this register from EL2 are trapped to EL3 using AArch64.

G6.3.32 SDCR, Secure Debug Control Register

The SDCR characteristics are:

Purpose

When EL3 is implemented and can use AArch32, controls debug and performance monitors functionality in Secure state.

Configurations

This register is only accessible in Secure state.

AArch32 System register SDCR can be mapped to AArch64 System register [MDCR_EL3](#), but this is not architecturally mandated.

This register is in the Warm reset domain. Some or all RW fields of this register have defined reset values. On a Warm or Cold reset these apply only if the PE resets into an Exception level that is using AArch32. Otherwise, on a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

SDCR is a 32-bit register.

Field descriptions

The SDCR bit assignments are:

Bits [31:22]

Reserved, RES0.

EPMAD, bit [21]

External debug interface Performance Monitors registers disable. This disables access to these registers by an external debugger:

- 0 Access to Performance Monitors registers from external debugger is permitted.
- 1 Access to Performance Monitors registers from external debugger is disabled, unless overridden by the IMPLEMENTATION DEFINED authentication interface.

If the Performance Monitors Extension is not implemented or does not support external debug interface accesses this bit is RES0.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to 0.

EDAD, bit [20]

External debug interface breakpoint and watchpoint register access disable. This disables access to these registers by an external debugger:

- 0 Access to breakpoint and watchpoint registers from external debugger is permitted.

- 1 Access to breakpoint and watchpoint registers from external debugger is disabled, unless overridden by the IMPLEMENTATION DEFINED authentication interface.

When this register has an architecturally-defined reset value, this field resets to 0.

Bits [19:18]

Reserved, RES0.

SPME, bit [17]

Secure Performance Monitors enable. This allows event counting in Secure state:

- 0 Event counting prohibited in Secure state.
In an ARMv8.0 or ARMv8.1 implementation, event counting is prohibited unless ExternalSecureNoninvasiveDebugEnabled() is TRUE, meaning this control is overridden by the IMPLEMENTATION DEFINED authentication interface.
- 1 Event counting allowed in Secure state.

If the Performance Monitors Extension is not implemented, this field is RES0.

When this register has an architecturally-defined reset value, this field resets to 0.

Bit [16]

Reserved, RES0.

SPD, bits [15:14]

AArch32 Secure privileged debug. Enables or disables debug exceptions from Secure state, other than Breakpoint Instruction exceptions. Valid values for this field are:

- 00 Legacy mode. Debug exceptions from Secure EL1 are enabled by the authentication interface.
- 10 Secure privileged debug disabled. Debug exceptions from Secure EL1 are disabled.
- 11 Secure privileged debug enabled. Debug exceptions from Secure EL1 are enabled.

Other values are reserved, and have the CONSTRAINED UNPREDICTABLE behavior that they must have the same behavior as 0b00. Software must not rely on this property as the behavior of reserved values might change in a future revision of the architecture.

If debug exceptions from Secure EL1 are enabled, then debug exceptions from Secure EL0 are also enabled.

Otherwise, debug exceptions from Secure EL0 are enabled only if `SDER32_EL3.SUIDEN == 1`.

Ignored in Non-secure state. Debug exceptions from Breakpoint Instruction exceptions are always enabled.

When this register has an architecturally-defined reset value, this field resets to 0.

Bits [13:0]

Reserved, RES0.

Accessing the SDCR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c1, c3, 1	000	001	0001	1111	0011

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	RW
x	0	1	-	-	-	RW
x	1	1	-	n/a	-	RW

If EL3 is implemented and is using AArch64, any read or write to SDCR from Secure EL1 using AArch32 is trapped as an exception to EL3.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 0)$:
 - If $HSTR_EL2.T1 == 1$, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 1) \ \&\& \ (HCR_EL2.TGE == 0)$:
 - If $HSTR_EL2.T1 == 1$, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $HSTR.T1 == 1$, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

G6.3.33 SDER, Secure Debug Enable Register

The SDER characteristics are:

Purpose

Controls invasive and non-invasive debug in the Secure EL0 mode.

Configurations

This register is only accessible in Secure state.

AArch32 System register SDER is architecturally mapped to AArch64 System register [SDER32_EL3](#).

If EL3 is not implemented and EL1 supports AArch32, SDER is implemented only if the implemented Security state is Secure state.

This register is in the Warm reset domain. Some or all RW fields of this register have defined reset values. On a Warm or Cold reset these apply only if the PE resets into an Exception level that is using AArch32. Otherwise, on a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

SDER is a 32-bit register.

Field descriptions

The SDER bit assignments are:

Bits [31:2]

Reserved, RES0.

SUNIDEN, bit [1]

Secure User Non-Invasive Debug Enable:

- 0 Performance Monitors event counting prohibited in Secure EL0 unless allowed by [MDCR_EL3.SPME](#), [SDCR.SPME](#).
In an ARMv8.0 or ARMv8.1 implementation, event counting can also be allowed using the IMPLEMENTATION DEFINED authentication interface `ExternalSecureNoninvasiveDebugEnabled()`.
- 1 Performance Monitors event counting allowed in Secure EL0.

When this register has an architecturally-defined reset value, this field resets to 0.

SUIDEN, bit [0]

Secure User Invasive Debug Enable:

- 0 Debug exceptions other than Breakpoint Instruction exceptions from Secure EL0 are disabled, unless enabled by [MDCR_EL3.SPD32](#) or [SDCR.SPD](#).
- 1 Debug exceptions from Secure EL0 are enabled.

When this register has an architecturally-defined reset value, this field resets to 0.

Accessing the SDER

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c1, c1, 1	000	001	0001	1111	0001

Accessibility

The register is accessible in software as follows:

Configuration	Control			Accessibility			
	E2H	TGE	NS	EL0	EL1	EL2	EL3
EL3 is not implemented.	x	x	0	-	RW	n/a	n/a
EL3 is not implemented.	x	0	1	-	-	-	n/a
EL3 is not implemented.	x	1	1	-	n/a	-	n/a
EL3 is using AArch64.	x	x	0	-	RW	n/a	n/a
EL3 is using AArch64.	x	0	1	-	-	-	n/a
EL3 is using AArch64.	x	1	1	-	n/a	-	n/a
EL3 is using AArch32.	x	x	0	-	n/a	n/a	RW
EL3 is using AArch32.	x	0	1	-	-	-	RW
EL3 is using AArch32.	x	1	1	-	n/a	-	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If HSTR_EL2.T1==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If HSTR_EL2.T1==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If HSTR.T1==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

G6.4 Performance Monitors registers

This section lists the Performance Monitors registers in AArch32.

G6.4.1 PMCCFILTR, Performance Monitors Cycle Count Filter Register

The PMCCFILTR characteristics are:

Purpose

Determines the modes in which the Cycle Counter, [PMCCNTR](#), increments.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register PMCCFILTR is architecturally mapped to AArch64 System register [PMCCFILTR_ELO](#).

AArch32 System register PMCCFILTR is architecturally mapped to External register [PMCCFILTR_ELO](#).

This register is in the Warm reset domain. Some or all RW fields of this register have defined reset values. On a Warm or Cold reset these apply only if the PE resets into an Exception level that is using AArch32. Otherwise, on a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMCCFILTR is a 32-bit register.

Field descriptions

The PMCCFILTR bit assignments are:

P, bit [31]

Privileged filtering bit. Controls counting in EL1. If EL3 is implemented, then counting in Non-secure EL1 is further controlled by the NSK bit. The possible values of this bit are:

- 0 Count cycles in EL1.
- 1 Do not count cycles in EL1.

When this register has an architecturally-defined reset value, this field resets to 0.

U, bit [30]

User filtering bit. Controls counting in EL0. If EL3 is implemented, then counting in Non-secure EL0 is further controlled by the NSU bit. The possible values of this bit are:

- 0 Count cycles in EL0.
- 1 Do not count cycles in EL0.

When this register has an architecturally-defined reset value, this field resets to 0.

NSK, bit [29]

Non-secure EL1 (kernel) modes filtering bit. Controls counting in Non-secure EL1. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of P, cycles in Non-secure EL1 are counted.

Otherwise, cycles in Non-secure EL1 are not counted.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to 0.

NSU, bit [28]

Non-secure EL0 (Unprivileged) filtering. Controls counting in Non-secure EL0. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of U, cycles in Non-secure EL0 are counted.

Otherwise, cycles in Non-secure EL0 are not counted.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to 0.

NSH, bit [27]

Non-secure EL2 (Hyp mode) filtering bit. Controls counting in Non-secure EL2. If EL2 is not implemented, this bit is RES0.

0 Do not count cycles in EL2.

1 Count cycles in EL2.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to 0.

Bits [26:0]

Reserved, RES0.

Accessing the PMCCFILTR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c14, c15, 7	000	111	1110	1111	1111

PMCCFILTR can also be accessed by using [PMXEVTYPER](#) with [PMSELR](#).SEL set to 0b11111.

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	RW	RW	n/a	RW
x	0	1	RW	RW	RW	RW
x	1	1	RW	n/a	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- In both security states, and not dependent on other bits:
 - If `PMUSERENR.EN==0`, accesses to this register from EL0 are trapped to Undefined mode.
 - If `PMUSERENR_EL0.EN==0`, accesses to this register from EL0 are trapped to EL1.
- When EL2 is implemented and is using AArch64 and `SCR_EL3.NS == 1`:
 - If `MDCR_EL2.TPM==1`, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and `SCR_EL3.NS == 1`:
 - If `HDCR.TPM==1`, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.
- When EL3 is implemented and is using AArch64:
 - If `MDCR_EL3.TPM==1`, accesses to this register from EL0, EL1, and EL2 are trapped to EL3.

G6.4.2 PMCCNTR, Performance Monitors Cycle Count Register

The PMCCNTR characteristics are:

Purpose

Holds the value of the processor Cycle Counter, CCNT, that counts processor clock cycles. See [Time as measured by the Performance Monitors cycle counter on page D5-2139](#) for more information.

[PMCCFILTR](#) determines the modes and states in which the PMCCNTR can increment.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register PMCCNTR is architecturally mapped to AArch64 System register [PMCCNTR_ELO](#).

AArch32 System register PMCCNTR is architecturally mapped to External register [PMCCNTR_ELO](#).

All counters are subject to any changes in clock frequency, including clock stopping caused by the WFI and WFE instructions. This means that it is CONstrained UNPREDICTABLE whether or not PMCCNTR continues to increment when clocks are stopped by WFI and WFE instructions.

This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMCCNTR is a 64-bit register that can also be accessed as a 32-bit value. If it is accessed as a 32-bit register, accesses read and write bits [31:0] and do not modify bits [63:32].

Field descriptions

The PMCCNTR bit assignments are:

When accessing as a 32-bit register:

CCNT, bits [31:0]

Cycle count. Depending on the values of [PMCR](#).{LC,D}, this field increments in one of the following ways:

- Every processor clock cycle.
- Every 64th processor clock cycle.

Writing 1 to [PMCR.C](#) sets this field to 0.

When accessing as a 64-bit register:

CCNT, bits [63:0]

Cycle count. Depending on the values of **PMCR**.{LC,D}, this field increments in one of the following ways:

- Every processor clock cycle.
- Every 64th processor clock cycle.

Writing 1 to **PMCR.C** sets this field to 0.

Accessing the PMCCNTR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c9, c13, 0	000	000	1001	1111	1101

This register can be read using MRRC with the following syntax:

MRRC <syntax>

This register can be written using MCRR with the following syntax:

MCRR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	coproc	CRm
p15, 0, <Rt>, <Rt2>, c9	0000	1111	1001

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	RW	RW	n/a	RW
x	0	1	RW	RW	RW	RW
x	1	1	RW	n/a	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- In both security states, and not dependent on other bits:
 - If `PMUSERENR.CR==0`, and `PMUSERENR.EN==0`, read accesses to this register from EL0 are trapped to Undefined mode.
 - If `PMUSERENR_EL0.CR==0`, and `PMUSERENR_EL0.EN==0`, read accesses to this register from EL0 are trapped to EL1.
 - If `PMUSERENR.EN==0`, write accesses to this register from EL0 are trapped to Undefined mode.
 - If `PMUSERENR_EL0.EN==0`, write accesses to this register from EL0 are trapped to EL1.
- When EL2 is implemented and is using AArch64 and `(SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0)`:
 - If `HSTR_EL2.T9==1`, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and `SCR_EL3.NS == 1`:
 - If `MDCR_EL2.TPM==1`, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and `(SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0)`:
 - If `HSTR_EL2.T9==1`, Non-secure write accesses to this register from EL0 and EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and `SCR_EL3.NS == 1`:
 - If `HDCR.TPM==1`, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.
 - If `HSTR.T9==1`, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.
- When EL3 is implemented and is using AArch64:
 - If `MDCR_EL3.TPM==1`, accesses to this register from EL0, EL1, and EL2 are trapped to EL3.

G6.4.3 PMCEID0, Performance Monitors Common Event Identification register 0

The PMCEID0 characteristics are:

Purpose

Defines which common architectural and common microarchitectural feature events in the range 0x000 to 0x01F are implemented. If a particular bit is set to 1, then the event for that bit is implemented.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register PMCEID0 is architecturally mapped to AArch64 System register [PMCEID0_EL0](#)[31:0].

AArch32 System register PMCEID0 is architecturally mapped to External register [PMCEID0](#)[31:0].

Attributes

PMCEID0 is a 32-bit register.

Field descriptions

The PMCEID0 bit assignments are:

ID[31:0], bits [31:0]

PMCEID0[n] maps to event n. For a list of event numbers and descriptions, see [Events, event numbers, and mnemonics on page D5-2152](#).

For each bit:

0 The common event is not implemented.

1 The common event is implemented.

Bits that map to reserved event numbers are reserved to identify events that might be defined in future revisions to the architecture.

Events that do not require additional features in the PMU can be defined retrospectively, meaning that they can be implemented as part of a PMUv3 implementation.

Accessing the PMCEID0

This register can be read using MRC with the following syntax:

MRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c9, c12, 6	000	110	1001	1111	1100

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	RO	RO	n/a	RO
x	0	1	RO	RO	RO	RO
x	1	1	RO	n/a	RO	RO

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- In both security states, and not dependent on other bits:
 - If `PMUSERENR.EN==0`, read accesses to this register from EL0 are trapped to Undefined mode.
 - If `PMUSERENR_EL0.EN==0`, read accesses to this register from EL0 are trapped to EL1.
- When EL2 is implemented and is using AArch64 and `(SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0)`:
 - If `HSTR_EL2.T9==1`, Non-secure read accesses to this register from EL0 and EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and `SCR_EL3.NS == 1`:
 - If `MDCR_EL2.TPM==1`, Non-secure read accesses to this register from EL0 and EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and `SCR_EL3.NS == 1`:
 - If `HDCR.TPM==1`, Non-secure read accesses to this register from EL0 and EL1 are trapped to Hyp mode.
 - If `HSTR.T9==1`, Non-secure read accesses to this register from EL0 and EL1 are trapped to Hyp mode.
- When EL3 is implemented and is using AArch64:
 - If `MDCR_EL3.TPM==1`, read accesses to this register from EL0, EL1, and EL2 are trapped to EL3.

G6.4.4 PMCEID1, Performance Monitors Common Event Identification register 1

The PMCEID1 characteristics are:

Purpose

Defines which common architectural and common microarchitectural feature events in the range 0x020 to 0x03F are implemented. If a particular bit is set to 1, then the event for that bit is implemented.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register PMCEID1 is architecturally mapped to AArch64 System register [PMCEID1_EL0](#)[31:0].

AArch32 System register PMCEID1 is architecturally mapped to External register [PMCEID1](#)[31:0].

Attributes

PMCEID1 is a 32-bit register.

Field descriptions

The PMCEID1 bit assignments are:

ID[63:32], bits [31:0]

PMCEID1[n] maps to event (n + 32). For a list of event numbers and descriptions, see [Events, event numbers, and mnemonics on page D5-2152](#).

For each bit:

0 The common event is not implemented.

1 The common event is implemented.

Bits that map to reserved event numbers are reserved to identify events that might be defined in future revisions to the architecture.

Events that do not require additional features in the PMU can be defined retrospectively, meaning that they can be implemented as part of a PMUv3 implementation.

Accessing the PMCEID1

This register can be read using MRC with the following syntax:

MRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c9, c12, 7	000	111	1001	1111	1100

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	RO	RO	n/a	RO
x	0	1	RO	RO	RO	RO
x	1	1	RO	n/a	RO	RO

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- In both security states, and not dependent on other bits:
 - If `PMUSERENR.EN==0`, read accesses to this register from EL0 are trapped to Undefined mode.
 - If `PMUSERENR_EL0.EN==0`, read accesses to this register from EL0 are trapped to EL1.
- When EL2 is implemented and is using AArch64 and `(SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0)`:
 - If `HSTR_EL2.T9==1`, Non-secure read accesses to this register from EL0 and EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and `SCR_EL3.NS == 1`:
 - If `MDCR_EL2.TPM==1`, Non-secure read accesses to this register from EL0 and EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and `SCR_EL3.NS == 1`:
 - If `HDCR.TPM==1`, Non-secure read accesses to this register from EL0 and EL1 are trapped to Hyp mode.
 - If `HSTR.T9==1`, Non-secure read accesses to this register from EL0 and EL1 are trapped to Hyp mode.
- When EL3 is implemented and is using AArch64:
 - If `MDCR_EL3.TPM==1`, read accesses to this register from EL0, EL1, and EL2 are trapped to EL3.

G6.4.5 PMCEID2, Performance Monitors Common Event Identification register 2

The PMCEID2 characteristics are:

Purpose

Defines which common architectural and common microarchitectural feature events in the range 0x4000 to 0x401F are implemented. If a particular bit is set to 1, then the event for that bit is implemented.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register PMCEID2 is architecturally mapped to AArch64 System register [PMCEID0_EL0](#)[63:32].

AArch32 System register PMCEID2 is architecturally mapped to External register [PMCEID2](#)[63:32].

This register is introduced in ARMv8.1.

Attributes

PMCEID2 is a 32-bit register.

Field descriptions

The PMCEID2 bit assignments are:

ID[16415:16384], bits [31:0]

PMCEID2[31:0] maps to common events 0x4000 to 0x401F. For a list of event numbers and descriptions, see [Events, event numbers, and mnemonics on page D5-2152](#).

For each bit:

0 The common event is not implemented.

1 The common event is implemented.

Bits that map to reserved event numbers are reserved to identify events that might be defined in future revisions to the architecture.

Events that do not require additional features in the PMU can be defined retrospectively, meaning that they can be implemented as part of a PMUv3 implementation.

Accessing the PMCEID2

This register can be read using MRC with the following syntax:

MRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c9, c14, 4	000	100	1001	1111	1110

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	RO	RO	n/a	RO
x	0	1	RO	RO	RO	RO
x	1	1	RO	n/a	RO	RO

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- In both security states, and not dependent on other bits:
 - If `PMUSERENR.EN==0`, read accesses to this register from EL0 are trapped to Undefined mode.
 - If `PMUSERENR_EL0.EN==0`, read accesses to this register from EL0 are trapped to EL1.

G6.4.6 PMCEID3, Performance Monitors Common Event Identification register 3

The PMCEID3 characteristics are:

Purpose

Defines which common architectural and common microarchitectural feature events in the range 0x4020 to 0x403F are implemented. If a particular bit is set to 1, then the event for that bit is implemented.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register PMCEID3 is architecturally mapped to AArch64 System register [PMCEID1_EL0](#)[63:32].

AArch32 System register PMCEID3 is architecturally mapped to External register [PMCEID3](#)[63:32].

This register is introduced in ARMv8.1.

Attributes

PMCEID3 is a 32-bit register.

Field descriptions

The PMCEID3 bit assignments are:

ID[16447:16416], bits [31:0]

PMCEID3[31:0] maps to common events 0x4020 to 0x403F. For a list of event numbers and descriptions, see [Events, event numbers, and mnemonics on page D5-2152](#).

For each bit:

0 The common event is not implemented.

1 The common event is implemented.

Bits that map to reserved event numbers are reserved to identify events that might be defined in future revisions to the architecture.

Events that do not require additional features in the PMU can be defined retrospectively, meaning that they can be implemented as part of a PMUv3 implementation.

Accessing the PMCEID3

This register can be read using MRC with the following syntax:

MRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c9, c14, 5	000	101	1001	1111	1110

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	RO	RO	n/a	RO
x	0	1	RO	RO	RO	RO
x	1	1	RO	n/a	RO	RO

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- In both security states, and not dependent on other bits:
 - If `PMUSERENR.EN==0`, read accesses to this register from EL0 are trapped to Undefined mode.
 - If `PMUSERENR_EL0.EN==0`, read accesses to this register from EL0 are trapped to EL1.

G6.4.7 PMCNTENCLR, Performance Monitors Count Enable Clear register

The PMCNTENCLR characteristics are:

Purpose

Disables the Cycle Count Register, [PMCCNTR](#), and any implemented event counters [PMEVCNTR<n>](#). Reading this register shows which counters are enabled.

PMCNTENCLR is used in conjunction with the [PMCNTENSET](#) register.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register PMCNTENCLR is architecturally mapped to AArch64 System register [PMCNTENCLR_ELO](#).

AArch32 System register PMCNTENCLR is architecturally mapped to External register [PMCNTENCLR_ELO](#).

This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMCNTENCLR is a 32-bit register.

Field descriptions

The PMCNTENCLR bit assignments are:

C, bit [31]

[PMCCNTR](#) disable bit. Disables the cycle counter register. Possible values are:

- 0 When read, means the cycle counter is disabled. When written, has no effect.
- 1 When read, means the cycle counter is enabled. When written, disables the cycle counter.

P<n>, bit [n], for n = 0 to 30

Event counter disable bit for [PMEVCNTR<n>](#).

Bits [30:N] are RAZ/WI. When EL2 is implemented, in Non-secure EL1 and EL0, N is the value in [MDCR_EL2.HPMN](#) if EL2 is using AArch64 or in [HDCR.HPMN](#) if EL2 is using AArch32.

Otherwise, N is the value in [PMCR.N](#).

Possible values of each bit are:

- 0 When read, means that [PMEVCNTR<n>](#) is disabled. When written, has no effect.
- 1 When read, means that [PMEVCNTR<n>](#) is enabled. When written, disables [PMEVCNTR<n>](#).

Accessing the PMCNTENCLR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c9, c12, 2	000	010	1001	1111	1100

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	RW	RW	n/a	RW
x	0	1	RW	RW	RW	RW
x	1	1	RW	n/a	RW	RW

If EL2 is implemented, in Non-secure EL1 and EL0 modes, the value of [HDCR.HPMN](#) or [MDCR_EL2.HPMN](#) can change the behavior of accesses to PMCNTENCLR. See the description of the P<n> bit.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- In both security states, and not dependent on other bits:
 - If [PMUSERENR.EN](#)==0, accesses to this register from EL0 are trapped to Undefined mode.
 - If [PMUSERENR_EL0.EN](#)==0, accesses to this register from EL0 are trapped to EL1.
- When EL2 is implemented and is using AArch64 and ([SCR_EL3.NS](#) == 1) && ([HCR_EL2.E2H](#) == 0):
 - If [HSTR_EL2.T9](#)==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and [SCR_EL3.NS](#) == 1:
 - If [MDCR_EL2.TPM](#)==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and ([SCR_EL3.NS](#) == 1) && ([HCR_EL2.E2H](#) == 1) && ([HCR_EL2.TGE](#) == 0):
 - If [HSTR_EL2.T9](#)==1, Non-secure write accesses to this register from EL0 and EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and [SCR_EL3.NS](#) == 1:
 - If [HSTR.T9](#)==1, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.
- When EL3 is implemented and is using AArch64:
 - If [MDCR_EL3.TPM](#)==1, accesses to this register from EL0, EL1, and EL2 are trapped to EL3.

G6.4.8 PMCNTENSET, Performance Monitors Count Enable Set register

The PMCNTENSET characteristics are:

Purpose

Enables the Cycle Count Register, [PMCCNTR](#), and any implemented event counters [PMEVCNTR<n>](#). Reading this register shows which counters are enabled.

PMCNTENSET is used in conjunction with the [PMCNTENCLR](#) register.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register PMCNTENSET is architecturally mapped to AArch64 System register [PMCNTENSET_EL0](#).

AArch32 System register PMCNTENSET is architecturally mapped to External register [PMCNTENSET_EL0](#).

This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMCNTENSET is a 32-bit register.

Field descriptions

The PMCNTENSET bit assignments are:

C, bit [31]

[PMCCNTR](#) enable bit. Enables the cycle counter register. Possible values are:

- 0 When read, means the cycle counter is disabled. When written, has no effect.
- 1 When read, means the cycle counter is enabled. When written, enables the cycle counter.

P<n>, bit [n], for n = 0 to 30

Event counter enable bit for [PMEVCNTR<n>](#).

Bits [30:N] are RAZ/WI. When EL2 is implemented, in Non-secure EL1 and EL0, N is the value in [MDCR_EL2.HPMN](#), if EL2 is using AArch64 or in [HDCR.HPMN](#) if EL2 is using AArch32. Otherwise, N is the value in [PMCR.N](#).

Possible values of each bit are:

- 0 When read, means that [PMEVCNTR<n>](#) is disabled. When written, has no effect.
- 1 When read, means that [PMEVCNTR<n>](#) event counter is enabled. When written, enables [PMEVCNTR<n>](#).

Accessing the PMCNTENSET

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c9, c12, 1	000	001	1001	1111	1100

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	RW	RW	n/a	RW
x	0	1	RW	RW	RW	RW
x	1	1	RW	n/a	RW	RW

If EL2 is implemented, in Non-secure EL1 and EL0 modes, the value of [HDCR.HPMN](#) can change the behavior of accesses to [PMCNTENSET](#). See the description of the P<n> bit.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- In both security states, and not dependent on other bits:
 - If [PMUSERENR.EN](#)==0, accesses to this register from EL0 are trapped to Undefined mode.
 - If [PMUSERENR_EL0.EN](#)==0, accesses to this register from EL0 are trapped to EL1.
- When EL2 is implemented and is using AArch64 and ([SCR_EL3.NS](#) == 1) && ([HCR_EL2.E2H](#) == 0):
 - If [HSTR_EL2.T9](#)==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and [SCR_EL3.NS](#) == 1:
 - If [MDCR_EL2.TPM](#)==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and ([SCR_EL3.NS](#) == 1) && ([HCR_EL2.E2H](#) == 1) && ([HCR_EL2.TGE](#) == 0):
 - If [HSTR_EL2.T9](#)==1, Non-secure write accesses to this register from EL0 and EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and [SCR_EL3.NS](#) == 1:
 - If [HDCR.TPM](#)==1, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.
 - If [HSTR.T9](#)==1, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.
- When EL3 is implemented and is using AArch64:
 - If [MDCR_EL3.TPM](#)==1, accesses to this register from EL0, EL1, and EL2 are trapped to EL3.

G6.4.9 PMCR, Performance Monitors Control Register

The PMCR characteristics are:

Purpose

Provides details of the Performance Monitors implementation, including the number of counters implemented, and configures and controls the counters.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register PMCR is architecturally mapped to AArch64 System register [PMCR_ELO](#).

AArch32 System register PMCR[6:0] is architecturally mapped to External register [PMCR_ELO](#)[6:0].

This register is in the Warm reset domain. Some or all RW fields of this register have defined reset values. On a Warm or Cold reset these apply only if the PE resets into an Exception level that is using AArch32. Otherwise, on a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMCR is a 32-bit register.

Field descriptions

The PMCR bit assignments are:

31	24 23	16 15	11 10	7 6	5	4	3	2	1	0
IMP	IDCODE	N	RES0	LCDP	X	D	C	P	E	

IMP, bits [31:24]

Implementer code. This field is RO with an IMPLEMENTATION DEFINED value.

The implementer codes are allocated by ARM. Values have the same interpretation as bits [31:24] of the [MIDR](#).

IDCODE, bits [23:16]

Identification code. This field is RO with an IMPLEMENTATION DEFINED value.

Each implementer must maintain a list of identification codes that is specific to the implementer. A specific implementation is identified by the combination of the implementer code and the identification code.

N, bits [15:11]

Number of event counters. A RO field that indicates the number counters implemented. A value of `0b00000` in this field indicates that only the Cycle Count Register [PMCCNTR](#) is implemented.

The value of this field is the number of event counters implemented. This value is in the range of `0b00000`, in which case only the [PMCCNTR](#) is implemented, to `0b11111`, which indicates that the [PMCCNTR](#) and 31 event counters are implemented.

In an implementation that includes EL2, reads of this field from Non-secure EL1 and Non-secure EL0 return the value of [HDCR.HPMN](#) if EL2 is using AArch32, or the value of [MDCR_EL2.HPMN](#) if EL2 is using AArch64.

Bits [10:7]

Reserved, RES0.

LC, bit [6]

Long cycle counter enable. Determines which [PMCCNTR](#) bit generates an overflow recorded by [PMOVSRR\[31\]](#).

- 0 Cycle counter overflow on increment that changes [PMCCNTR\[31\]](#) from 1 to 0.
- 1 Cycle counter overflow on increment that changes [PMCCNTR\[63\]](#) from 1 to 0.

ARM deprecates use of $PMCR.LC = 0$.

This field resets to a value that is architecturally UNKNOWN.

DP, bit [5]

Disable cycle counter when event counting is prohibited. The possible values of this bit are:

- 0 [PMCCNTR](#), if enabled, counts when event counting is prohibited.
- 1 [PMCCNTR](#) does not count when event counting is prohibited.

Counting events is never prohibited in Non-secure state. However, there are some restrictions on counting events in Secure state. For more information about the interaction between the Performance Monitors and EL3, see [Interaction with EL3 on page D5-2145](#)

When EL3 is not implemented, this field is RES0:

- When [ARMv8.1-PMU](#) is not implemented.
- When [ARMv8.1-PMU](#) is implemented, only if EL2 is not implemented.

Otherwise this field is RW.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to 0.

X, bit [4]

Enable export of events in an IMPLEMENTATION DEFINED event stream. The possible values of this bit are:

- 0 Do not export events.
- 1 Export events where not prohibited.

This field enables the exporting of events over an event bus to another device, for example to an OPTIONAL trace macrocell. If the implementation does not include such an event bus then this field is RAZ/WI, otherwise it is an RW field.

In an implementation that includes an event bus, no events are exported when counting is prohibited.

This field does not affect the generation of Performance Monitors overflow interrupt requests or signaling to a cross-trigger interface (CTI) that can be implemented as signals exported from the PE.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to 0.

D, bit [3]

Clock divider. The possible values of this bit are:

- 0 When enabled, [PMCCNTR](#) counts every clock cycle.
- 1 When enabled, [PMCCNTR](#) counts once every 64 clock cycles.

This bit is RW.

If $PMCR.LC = 1$, this bit is ignored and the cycle counter counts every clock cycle.

ARM deprecates use of $PMCR.D = 1$.

When this register has an architecturally-defined reset value, this field resets to 0.

C, bit [2]

Cycle counter reset. This bit is WO. The effects of writing to this bit are:

- 0 No action.
- 1 Reset [PMCCNTR](#) to zero.

This bit is always RAZ.

Resetting **PMCCNTR** does not clear the **PMCCNTR** overflow bit to 0.

P, bit [1]

Event counter reset. This bit is WO. The effects of writing to this bit are:

0 No action.

1 Reset all event counters accessible in the current EL, not including **PMCCNTR**, to zero.

This bit is always RAZ.

In Non-secure EL0 and EL1, if EL2 is implemented, a write of 1 to this bit does not reset event counters that **HDCR.HPMN** or **MDCR_EL2.HPMN** reserves for EL2 use.

In EL2 and EL3, a write of 1 to this bit resets all the event counters.

Resetting the event counters does not clear any overflow bits to 0.

E, bit [0]

Enable. The possible values of this bit are:

0 All counters that are accessible at Non-secure EL1, including **PMCCNTR**, are disabled.

1 All counters that are accessible at Non-secure EL1 are enabled by **PMCNTENSET**.

This bit is RW.

If EL2 is implemented, this bit does not affect the operation of event counters that **HDCR.HPMN** or **MDCR_EL2.HPMN** reserves for EL2 use.

When this register has an architecturally-defined reset value, this field resets to 0.

Accessing the PMCR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c9, c12, 0	000	000	1001	1111	1100

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	RW	RW	n/a	RW
x	0	1	RW	RW	RW	RW
x	1	1	RW	n/a	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- In both security states, and not dependent on other bits:
 - If `PMUSERENR.EN==0`, accesses to this register from EL0 are trapped to Undefined mode.
 - If `PMUSERENR_EL0.EN==0`, accesses to this register from EL0 are trapped to EL1.
- When EL2 is implemented and is using AArch64 and `(SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0)`:
 - If `HSTR_EL2.T9==1`, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and `SCR_EL3.NS == 1`:
 - If `MDCR_EL2.TPM==1`, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.
 - If `MDCR_EL2.TPMCR==1`, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and `(SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0)`:
 - If `HSTR_EL2.T9==1`, Non-secure write accesses to this register from EL0 and EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and `SCR_EL3.NS == 1`:
 - If `HDCR.TPM==1`, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.
 - If `HDCR.TPMCR==1`, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.
 - If `HSTR.T9==1`, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.
- When EL3 is implemented and is using AArch64:
 - If `MDCR_EL3.TPM==1`, accesses to this register from EL0, EL1, and EL2 are trapped to EL3.

G6.4.10 PMEVCNTR<n>, Performance Monitors Event Count Registers, n = 0 - 30

The PMEVCNTR<n> characteristics are:

Purpose

Holds event counter n, which counts events, where n is 0 to 30.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register PMEVCNTR<n> is architecturally mapped to AArch64 System register [PMEVCNTR<n>_EL0](#).

AArch32 System register PMEVCNTR<n> is architecturally mapped to External register [PMEVCNTR<n>_EL0](#).

This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMEVCNTR<n> is a 32-bit register.

Field descriptions

The PMEVCNTR<n> bit assignments are:

Bits [31:0]

Event counter n. Value of event counter n, where n is the number of this register and is a number from 0 to 30.

Accessing the PMEVCNTR<n>

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c14, <CRm>, <opc2>	000	n<2:0>	1110	1111	10:n<4:3>

- <opc2> is in the range 0 - 7.
- <CRm> is in the range c8 - c11.

PMEVCNTR<n> can also be accessed by using [PMXEVCNTR](#) with [PMSELR](#).SEL set to the value of <n>.

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	RW	RW	n/a	RW
x	0	1	RW	RW	RW	RW
x	1	1	RW	n/a	RW	RW

If <n> is greater than or equal to the number of accessible counters, reads and writes of PMEVCNTR<n> are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a NOP.
- In Non-secure state, for an access from PL1 or a permitted access from PL0, if [PMSELR.SEL](#), or [PMSELR_EL0.SEL](#) if EL1 is using AArch64, is greater than or equal to the number of accessible counters but is less than the number of implemented counters, the register access is trapped to EL2. Accesses from PL0 are permitted when:
 - EL1 is using AArch32 and the value of [PMUSERENR.EN](#) is 1.
 - EL1 is using AArch64 and the value of [PMUSERENR_EL0.EN](#) is 1.

———— Note —————

In an implementation that includes EL2, in Non-secure state at EL0 and EL1:

- If EL2 is using AArch32, [HDCR.HPMN](#) identifies the number of accessible counters.
- If EL2 is using AArch64, [MDCR_EL2.HPMN](#) identifies the number of accessible counters.

Otherwise, the number of accessible counters is the number of implemented counters.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- In both security states, and not dependent on other bits:
 - If [PMUSERENR.EN](#)==0, and [PMUSERENR.ER](#)==0, read accesses to this register from EL0 are trapped to Undefined mode.
 - If [PMUSERENR.EN](#)==0, write accesses to this register from EL0 are trapped to Undefined mode.
 - If [PMUSERENR_EL0.EN](#)==0, and [PMUSERENR_EL0.ER](#)==0, read accesses to this register from EL0 are trapped to EL1.
 - If [PMUSERENR_EL0.EN](#)==0, write accesses to this register from EL0 are trapped to EL1.
- When EL2 is implemented and is using AArch64 and [SCR_EL3.NS](#) == 1:
 - If [MDCR_EL2.TPM](#)==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If [HDCR.TPM==1](#), Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.
- When EL3 is implemented and is using AArch64:
 - If [MDCR_EL3.TPM==1](#), accesses to this register from EL0, EL1, and EL2 are trapped to EL3.

G6.4.11 PMEVTYPER<n>, Performance Monitors Event Type Registers, n = 0 - 30

The PMEVTYPER<n> characteristics are:

Purpose

Configures event counter n, where n is 0 to 30.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register PMEVTYPER<n> is architecturally mapped to AArch64 System register [PMEVTYPER<n>_EL0](#).

AArch32 System register PMEVTYPER<n> is architecturally mapped to External register [PMEVTYPER<n>_EL0](#).

This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMEVTYPER<n> is a 32-bit register.

Field descriptions

The PMEVTYPER<n> bit assignments are:

P, bit [31]

Privileged filtering bit. Controls counting in EL1. If EL3 is implemented, then counting in Non-secure EL1 is further controlled by the NSK bit. The possible values of this bit are:

- 0 Count events in EL1.
- 1 Do not count events in EL1.

U, bit [30]

User filtering bit. Controls counting in EL0. If EL3 is implemented, then counting in Non-secure EL0 is further controlled by the NSU bit. The possible values of this bit are:

- 0 Count events in EL0.
- 1 Do not count events in EL0.

NSK, bit [29]

Non-secure EL1 (kernel) modes filtering bit. Controls counting in Non-secure EL1. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of P, events in Non-secure EL1 are counted.

Otherwise, events in Non-secure EL1 are not counted.

NSU, bit [28]

Non-secure EL0 (Unprivileged) filtering. Controls counting in Non-secure EL0. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of U, events in Non-secure EL0 are counted.

Otherwise, events in Non-secure EL0 are not counted.

NSH, bit [27]

Non-secure EL2 (Hyp mode) filtering bit. Controls counting in Non-secure EL2. If EL2 is not implemented, this bit is RES0.

0 Do not count events in EL2.

1 Count events in EL2.

Bit [26]

Reserved, RES0.

MT, bit [25]

Multithreading. When the implementation is multi-threaded, the valid values for this bit are:

0 Count events only on controlling PE.

1 Count events from any PE with the same affinity at level 1 and above as this PE.

When the implementation is not multi-threaded, this bit is RES0.

Note

- An implementation is described as multi-threaded when the lowest level of affinity consists of logical PEs that are implemented using a multi-threading type approach. That is, the performance of PEs at the lowest affinity level is highly interdependent. On such an implementation, the value of MPIDR_EL1.MT, when read at the highest implemented Exception level, is 1.
- Events from a different thread of a multithreaded implementation are not Attributable to the thread counting the event.

Bits [24:16]

Reserved, RES0.

evtCount[15:10], bits [15:10]

In ARMv8.2 and ARMv8.1

Extension to evtCount[9:0]. See evtCount[9:0] for more details.

In ARMv8.0.

Reserved, RES0.

evtCount[9:0], bits [9:0]

Event to count. The event number of the event that is counted by event counter **PMEVCNTR<n>**.

Software must program this field with an event that is supported by the PE being programmed.

There are three ranges of event numbers:

- Event numbers in the range 0x000 to 0x03F are common architectural and microarchitectural events.
- Event numbers in the range 0x040 to 0x0BF are ARM recommended common architectural and microarchitectural events.
- Event numbers in the range 0x0C0 to 0x3FF are IMPLEMENTATION DEFINED events.

If evtCount is programmed to an event that is reserved or not supported by the PE, the behavior depends on the event type:

- For the range 0x000 to 0x03F, no events are counted, and the value returned by a direct or external read of the evtCount field is the value written to the field.
- For IMPLEMENTATION DEFINED events, it is UNPREDICTABLE what event, if any, is counted, and the value returned by a direct or external read of the evtCount field is UNKNOWN.

———— **Note** —————

UNPREDICTABLE means the event must not expose privileged information.

ARM recommends that the behavior across a family of implementations is defined such that if a given implementation does not include an event from a set of common IMPLEMENTATION DEFINED events, then no event is counted and the value read back on evtCount is the value written.

Accessing the PMEVTYPER<n>

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c14, <CRm>, <opc2>	000	n<2:0>	1110	1111	11:n<4:3>

- <opc2> is in the range 0 - 7.
- <CRm> is in the range c12 - c15.

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	RW	RW	n/a	n/a
x	0	1	RW	RW	RW	n/a
x	1	1	RW	n/a	RW	n/a

This register is accessible at EL0 when [PMUSERENR.EN](#) is set to 1.

PMEVTYPER<n> can also be accessed by using [PMXEVTYPER](#) with [PMSCLR.SEL](#) set to n.

If <n> is greater or equal to the number of accessible counters, reads and writes of PMEVTYPER<n> are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a NOP.

- In Non-secure state, for an access from PL1 or a permitted access from PL0, if [PMSELR.SEL](#), or [PMSELR_EL0.SEL](#) if EL1 is using AArch64, is greater than or equal to the number of accessible counters but is less than the number of implemented counters, the register access is trapped to EL2. Accesses from PL0 are permitted when:
 - EL1 is using AArch32 and the value of [PMUSERENR.EN](#) is 1.
 - EL1 is using AArch64 and the value of [PMUSERENR_EL0.EN](#) is 1.

———— **Note** —————

In an implementation that includes EL2, in Non-secure state at EL0 and EL1:

- If EL2 is using AArch32, [HDCR.HPMN](#) identifies the number of accessible counters.
- If EL2 is using AArch64, [MDCR_EL2.HPMN](#) identifies the number of accessible counters.

Otherwise, the number of accessible counters is the number of implemented counters.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- In both security states, and not dependent on other bits:
 - If [PMUSERENR.EN](#)==0, accesses to this register from EL0 are trapped to Undefined mode.
 - If [PMUSERENR_EL0.EN](#)==0, accesses to this register from EL0 are trapped to EL1.
- When EL2 is implemented and is using AArch64 and [SCR_EL3.NS](#) == 1:
 - If [MDCR_EL2.TPM](#)==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and [SCR_EL3.NS](#) == 1:
 - If [HDCR.TPM](#)==1, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.
- When EL3 is implemented and is using AArch64:
 - If [MDCR_EL3.TPM](#)==1, accesses to this register from EL0, EL1, and EL2 are trapped to EL3.

G6.4.12 PMINTENCLR, Performance Monitors Interrupt Enable Clear register

The PMINTENCLR characteristics are:

Purpose

Disables the generation of interrupt requests on overflows from the Cycle Count Register, [PMCCNTR](#), and the event counters [PMEVCNTR<n>](#). Reading the register shows which overflow interrupt requests are enabled.

PMINTENCLR is used in conjunction with the [PMINTENSET](#) register.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register PMINTENCLR is architecturally mapped to AArch64 System register [PMINTENCLR_EL1](#).

AArch32 System register PMINTENCLR is architecturally mapped to External register [PMINTENCLR_EL1](#).

This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMINTENCLR is a 32-bit register.

Field descriptions

The PMINTENCLR bit assignments are:

C, bit [31]

[PMCCNTR](#) overflow interrupt request disable bit. Possible values are:

- 0 When read, means the cycle counter overflow interrupt request is disabled. When written, has no effect.
- 1 When read, means the cycle counter overflow interrupt request is enabled. When written, disables the cycle count overflow interrupt request.

P<n>, bit [n], for n = 0 to 30

Event counter overflow interrupt request disable bit for [PMEVCNTR<n>](#).

When EL2 is implemented, in Non-secure EL1 and EL0, N is the value in [HDCR.HPMN](#). Otherwise, N is the value in [PMCR.N](#).

Bits [30:N] are RAZ/WI.

Possible values are:

- 0 When read, means that the [PMEVCNTR<n>](#) event counter interrupt request is disabled. When written, has no effect.
- 1 When read, means that the [PMEVCNTR<n>](#) event counter interrupt request is enabled. When written, disables the [PMEVCNTR<n>](#) interrupt request.

Accessing the PMINTENCLR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c9, c14, 2	000	010	1001	1111	1110

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	RW	RW	n/a	RW
x	0	1	RW	RW	RW	RW
x	1	1	RW	n/a	RW	RW

If EL2 is implemented, in Non-secure EL1 and EL0 modes, the value of [HDCR.HPMN](#) can change the behavior of accesses to [PMINTENCLR](#). See the description of the P<n> bit.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If [HSTR_EL2.T9](#)==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and SCR_EL3.NS == 1:
 - If [MDCR_EL2.TPM](#)==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If [HSTR_EL2.T9](#)==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If [HDCR.TPM](#)==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
 - If [HSTR.T9](#)==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
- When EL3 is implemented and is using AArch64:
 - If [MDCR_EL3.TPM](#)==1, accesses to this register from EL1 and EL2 are trapped to EL3.

G6.4.13 PMINTENSET, Performance Monitors Interrupt Enable Set register

The PMINTENSET characteristics are:

Purpose

Enables the generation of interrupt requests on overflows from the Cycle Count Register, [PMCCNTR](#), and the event counters [PMEVCNTR<n>](#). Reading the register shows which overflow interrupt requests are enabled.

PMINTENSET is used in conjunction with the [PMINTENCLR](#) register.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register PMINTENSET is architecturally mapped to AArch64 System register [PMINTENSET_EL1](#).

AArch32 System register PMINTENSET is architecturally mapped to External register [PMINTENSET_EL1](#).

This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMINTENSET is a 32-bit register.

Field descriptions

The PMINTENSET bit assignments are:

C, bit [31]

[PMCCNTR](#) overflow interrupt request enable bit. Possible values are:

- 0 When read, means the cycle counter overflow interrupt request is disabled. When written, has no effect.
- 1 When read, means the cycle counter overflow interrupt request is enabled. When written, enables the cycle count overflow interrupt request.

P<n>, bit [n], for n = 0 to 30

Event counter overflow interrupt request enable bit for [PMEVCNTR<n>](#).

When EL2 is implemented, in Non-secure EL1 and EL0, N is the value in [HDCR.HPMN](#). Otherwise, N is the value in [PMCR.N](#).

Bits [30:N] are RAZ/WI.

Possible values are:

- 0 When read, means that the [PMEVCNTR<n>](#) event counter interrupt request is disabled. When written, has no effect.
- 1 When read, means that the [PMEVCNTR<n>](#) event counter interrupt request is enabled. When written, enables the [PMEVCNTR<n>](#) interrupt request.

Accessing the PMINTENSET

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c9, c14, 1	000	001	1001	1111	1110

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	RW	RW	n/a	RW
x	0	1	RW	RW	RW	RW
x	1	1	RW	n/a	RW	RW

If EL2 is implemented, in Non-secure EL1 and EL0 modes, the value of [HDCR.HPMN](#) can change the behavior of accesses to [PMINTENSET](#). See the description of the P<n> bit.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If [HSTR_EL2.T9](#)==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and SCR_EL3.NS == 1:
 - If [MDCR_EL2.TPM](#)==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If [HSTR_EL2.T9](#)==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If [HDCR.TPM](#)==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
 - If [HSTR.T9](#)==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
- When EL3 is implemented and is using AArch64:
 - If [MDCR_EL3.TPM](#)==1, accesses to this register from EL1 and EL2 are trapped to EL3.

G6.4.14 PMOVSR, Performance Monitors Overflow Flag Status Register

The PMOVSR characteristics are:

Purpose

Contains the state of the overflow bit for the Cycle Count Register, [PMCCNTR](#), and each of the implemented event counters [PMEVCNTR<n>](#). Writing to this register clears these bits.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register PMOVSR is architecturally mapped to AArch64 System register [PMOVSLR_ELO](#).

AArch32 System register PMOVSR is architecturally mapped to External register [PMOVSLR_ELO](#).

This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMOVSR is a 32-bit register.

Field descriptions

The PMOVSR bit assignments are:

C, bit [31]

[PMCCNTR](#) overflow bit. Possible values are:

- 0 When read, means the cycle counter has not overflowed. When written, has no effect.
- 1 When read, means the cycle counter has overflowed. When written, clears the overflow bit to 0.

[PMCR.LC](#) controls whether an overflow is detected from [PMCCNTR\[31\]](#) or from [PMCCNTR\[63\]](#).

P<n>, bit [n], for n = 0 to 30

Event counter overflow clear bit for [PMEVCNTR<n>](#).

Bits [30:N] are RAZ/WI. When EL2 is implemented, in Non-secure EL1 and EL0, N is the value in [MDCR_EL2.HPMN](#) if EL2 is using AArch64 or in [HDCR.HPMN](#) if EL2 is using AArch32. Otherwise, N is the value in [PMCR.N](#).

Possible values of each bit are:

- 0 When read, means that [PMEVCNTR<n>](#) has not overflowed. When written, has no effect.
- 1 When read, means that [PMEVCNTR<n>](#) has overflowed. When written, clears the [PMEVCNTR<n>](#) overflow bit to 0.

Accessing the PMOVSR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c9, c12, 3	000	011	1001	1111	1100

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	RW	RW	n/a	RW
x	0	1	RW	RW	RW	RW
x	1	1	RW	n/a	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- In both security states, and not dependent on other bits:
 - If `PMUSERENR.EN==0`, accesses to this register from EL0 are trapped to Undefined mode.
 - If `PMUSERENR_EL0.EN==0`, accesses to this register from EL0 are trapped to EL1.
- When EL2 is implemented and is using AArch64 and `(SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0)`:
 - If `HSTR_EL2.T9==1`, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and `SCR_EL3.NS == 1`:
 - If `MDCR_EL2.TPM==1`, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and `(SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0)`:
 - If `HSTR_EL2.T9==1`, Non-secure write accesses to this register from EL0 and EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and `SCR_EL3.NS == 1`:
 - If `HDCR.TPM==1`, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.
 - If `HSTR.T9==1`, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.
- When EL3 is implemented and is using AArch64:
 - If `MDCR_EL3.TPM==1`, accesses to this register from EL0, EL1, and EL2 are trapped to EL3.

G6.4.15 PMOVSSET, Performance Monitors Overflow Flag Status Set register

The PMOVSSET characteristics are:

Purpose

Sets the state of the overflow bit for the Cycle Count Register, [PMCCNTR](#), and each of the implemented event counters [PMEVCNTR<n>](#).

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register PMOVSSET is architecturally mapped to AArch64 System register [PMOVSSET_EL0](#).

AArch32 System register PMOVSSET is architecturally mapped to External register [PMOVSSET_EL0](#).

This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMOVSSET is a 32-bit register.

Field descriptions

The PMOVSSET bit assignments are:

C, bit [31]

[PMCCNTR](#) overflow bit. Possible values are:

- 0 When read, means the cycle counter has not overflowed. When written, has no effect.
- 1 When read, means the cycle counter has overflowed. When written, sets the overflow bit to 1.

P<n>, bit [n], for n = 0 to 30

Event counter overflow set bit for [PMEVCNTR<n>](#).

Bits [30:N] are RAZ/WI. When EL2 is implemented, in Non-secure EL1 and EL0, N is the value in [MDCR_EL2.HPMN](#) if EL2 is using AArch64 or in [HDCR.HPMN](#) if EL2 is using AArch32. Otherwise, N is the value in [PMCR.N](#).

Possible values are:

- 0 When read, means that [PMEVCNTR<n>](#) has not overflowed. When written, has no effect.
- 1 When read, means that [PMEVCNTR<n>](#) has overflowed. When written, sets the [PMEVCNTR<n>](#) overflow bit to 1.

Accessing the PMOVSSET

This register can be read using MRC with the following syntax:

```
MRC <syntax>
```

This register can be written using MCR with the following syntax:

```
MCR <syntax>
```

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c9, c14, 3	000	011	1001	1111	1110

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	RW	RW	n/a	RW
x	0	1	RW	RW	RW	RW
x	1	1	RW	n/a	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- In both security states, and not dependent on other bits:
 - If `PMUSERENR.EN==0`, accesses to this register from EL0 are trapped to Undefined mode.
 - If `PMUSERENR_EL0.EN==0`, accesses to this register from EL0 are trapped to EL1.
- When EL2 is implemented and is using AArch64 and `(SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0)`:
 - If `HSTR_EL2.T9==1`, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and `SCR_EL3.NS == 1`:
 - If `MDCR_EL2.TPM==1`, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and `(SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0)`:
 - If `HSTR_EL2.T9==1`, Non-secure write accesses to this register from EL0 and EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and `SCR_EL3.NS == 1`:
 - If `HDCR.TPM==1`, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.
 - If `HSTR.T9==1`, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.
- When EL3 is implemented and is using AArch64:
 - If `MDCR_EL3.TPM==1`, accesses to this register from EL0, EL1, and EL2 are trapped to EL3.

G6.4.16 PMSELR, Performance Monitors Event Counter Selection Register

The PMSELR characteristics are:

Purpose

Selects the current event counter [PMEVCNTR<n>](#) or the cycle counter, CCNT.

PMSELR is used in conjunction with [PMXEVTYPER](#) to determine the event that increments a selected event counter, and the modes and states in which the selected counter increments.

It is also used in conjunction with [PMXVCNTR](#), to determine the value of a selected event counter.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register PMSELR is architecturally mapped to AArch64 System register [PMSELR_ELO](#).

This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMSELR is a 32-bit register.

Field descriptions

The PMSELR bit assignments are:

Bits [31:5]

Reserved, RES0.

SEL, bits [4:0]

Selects event counter, [PMEVCNTR<n>](#), where n is the value held in this field. This value identifies which event counter is accessed when a subsequent access to [PMXEVTYPER](#) or [PMXVCNTR](#) occurs.

This field can take any value from 0 ([0b00000](#)) to (PMCR.N)-1, or 31 ([0b11111](#)).

When PMSELR.SEL is [0b11111](#) it selects the cycle counter and:

- A read of the [PMXEVTYPER](#) returns the value of [PMCCFILTR](#).
- A write of the [PMXEVTYPER](#) writes to [PMCCFILTR](#).
- A read or write of [PMXVCNTR](#) has CONSTRAINED UNPREDICTABLE effects, that can be one of the following:
 - Access to [PMXVCNTR](#) is UNDEFINED.
 - Access to [PMXVCNTR](#) behaves as a NOP.
 - Access to [PMXVCNTR](#) behaves as if the register is RAZ/WI.
 - Access to [PMXVCNTR](#) behaves as if the PMSELR.SEL field contains an UNKNOWN value.

If this field is set to a value greater than or equal to the number of implemented counters, but not equal to 31, the results of access to [PMXEVTYPER](#) or [PMXVCNTR](#) are CONSTRAINED UNPREDICTABLE, and can be one of the following:

- Access to [PMXEVTYPER](#) or [PMXVCNTR](#) is UNDEFINED.

- Access to [PMXEVTYPER](#) or [PMXEVCNTR](#) behaves as a NOP.
- Access to [PMXEVTYPER](#) or [PMXEVCNTR](#) behaves as if the register is RAZ/WI.
- Access to [PMXEVTYPER](#) or [PMXEVCNTR](#) behaves as if the PMSELR.SEL field contains an UNKNOWN value.
- Access to [PMXEVTYPER](#) or [PMXEVCNTR](#) behaves as if the PMSELR.SEL field contains 0b11111.

Direct reads of this field return an UNKNOWN value.

Accessing the PMSELR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c9, c12, 5	000	101	1001	1111	1100

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	RW	RW	n/a	RW
x	0	1	RW	RW	RW	RW
x	1	1	RW	n/a	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- In both security states, and not dependent on other bits:
 - If [PMUSERENR.EN](#)==0, and [PMUSERENR.ER](#)==0, accesses to this register from EL0 are trapped to Undefined mode.
 - If [PMUSERENR_EL0.EN](#)==0, and [PMUSERENR_EL0.ER](#)==0, accesses to this register from EL0 are trapped to EL1.
- When EL2 is implemented and is using AArch64 and ([SCR_EL3.NS](#) == 1) && ([HCR_EL2.E2H](#) == 0):
 - If [HSTR_EL2.T9](#)==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and [SCR_EL3.NS](#) == 1:
 - If [MDCR_EL2.TPM](#)==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If [HSTR_EL2.T9](#)==1, Non-secure write accesses to this register from EL0 and EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If [HDCR.TPM](#)==1, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.
 - If [HSTR.T9](#)==1, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.
- When EL3 is implemented and is using AArch64:
 - If [MDCR_EL3.TPM](#)==1, accesses to this register from EL0, EL1, and EL2 are trapped to EL3.

G6.4.17 PMSWINC, Performance Monitors Software Increment register

The PMSWINC characteristics are:

Purpose

Increments a counter that is configured to count the Software increment event, event 0x00. For more information, see [SW_INCR](#).

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register PMSWINC is architecturally mapped to AArch64 System register [PMSWINC_ELO](#).

AArch32 System register PMSWINC is architecturally mapped to External register [PMSWINC_ELO](#).

Attributes

PMSWINC is a 32-bit register.

Field descriptions

The PMSWINC bit assignments are:

Bit [31]

Reserved, RES0.

P<n>, bit [n], for n = 0 to 30

Event counter software increment bit for [PMEVCNTR<n>](#).

Bits [30:N] are RAZ/WI. When EL2 is implemented, in Non-secure EL1 and EL0, N is the value in [MDCR_EL2.HPMN](#) if EL2 is using AArch64 or in [HDCR.HPMN](#) if EL2 is using AArch32. Otherwise, N is the value in [PMCR.N](#).

The effects of writing to this bit are:

- 0 No action. The write to this bit is ignored.
- 1 If [PMEVCNTR<n>](#) is enabled and configured to count the software increment event, increments [PMEVCNTR<n>](#) by 1. If [PMEVCNTR<n>](#) is disabled, or not configured to count the software increment event, the write to this bit is ignored.

Accessing the PMSWINC

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c9, c12, 4	000	100	1001	1111	1100

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	RW	RW	n/a	RW
x	0	1	RW	RW	RW	RW
x	1	1	RW	n/a	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- In both security states, and not dependent on other bits:
 - If `PMUSERENR.EN==0`, and `PMUSERENR.SW==0`, write accesses to this register from EL0 are trapped to Undefined mode.
 - If `PMUSERENR_EL0.EN==0`, and `PMUSERENR_EL0.SW==0`, write accesses to this register from EL0 are trapped to EL1.
- When EL2 is implemented and is using AArch64 and `(SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0)`:
 - If `HSTR_EL2.T9==1`, Non-secure write accesses to this register from EL0 and EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and `SCR_EL3.NS == 1`:
 - If `MDCR_EL2.TPM==1`, Non-secure write accesses to this register from EL0 and EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and `(SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0)`:
 - If `HSTR_EL2.T9==1`, Non-secure write accesses to this register from EL0 and EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and `SCR_EL3.NS == 1`:
 - If `HDCR.TPM==1`, Non-secure write accesses to this register from EL0 and EL1 are trapped to Hyp mode.
 - If `HSTR.T9==1`, Non-secure write accesses to this register from EL0 and EL1 are trapped to Hyp mode.
- When EL3 is implemented and is using AArch64:
 - If `MDCR_EL3.TPM==1`, write accesses to this register from EL0, EL1, and EL2 are trapped to EL3.

G6.4.18 PMUSERENR, Performance Monitors User Enable Register

The PMUSERENR characteristics are:

Purpose

Enables or disables User mode access to the Performance Monitors.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register PMUSERENR is architecturally mapped to AArch64 System register [PMUSERENR_ELO](#).

This register is in the Warm reset domain. Some or all RW fields of this register have defined reset values. On a Warm or Cold reset these apply only if the PE resets into an Exception level that is using AArch32. Otherwise, on a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMUSERENR is a 32-bit register.

Field descriptions

The PMUSERENR bit assignments are:

Bits [31:4]

Reserved, RES0.

ER, bit [3]

Event counter read trap control:

0 EL0 reads of the [PMXVCNTR](#) and [PMEVCNTR<n>](#), and EL0 read/write access to the [PMSELR](#), are trapped to Undefined mode if PMUSERENR.EN is also 0.

1 This control does not cause any instructions to be trapped.

When this register has an architecturally-defined reset value, this field resets to 0.

CR, bit [2]

Cycle counter read trap control:

0 EL0 reads of the [PMCCNTR](#) are trapped to Undefined mode if PMUSERENR.EN is also 0.

1 This control does not cause any instructions to be trapped.

When this register has an architecturally-defined reset value, this field resets to 0.

SW, bit [1]

Software increment write trap control:

0 EL0 writes to the [PMSWINC](#) are trapped to Undefined mode if PMUSERENR.EN is also 0.

1 This control does not cause any instructions to be trapped.
When this register has an architecturally-defined reset value, this field resets to 0.

EN, bit [0]

Traps EL0 accesses to the Performance Monitors registers to Undefined mode:

- 0 EL0 accesses to the Performance Monitors registers are trapped to Undefined mode, unless enabled by one of PMUSERENR.{ER, CR, SW}.
- 1 This control does not cause any instructions to be trapped. Software can access all PMU registers at EL0.

Note

- The PMUSERENR register is always RO at EL0 and not trapped by this bit.
- EL0 cannot read or write [PMINTENSET](#) and [PMINTENCLR](#).

When this register has an architecturally-defined reset value, this field resets to 0.

Accessing the PMUSERENR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c9, c14, 0	000	000	1001	1111	1110

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	RO	RW	n/a	RW
x	0	1	RO	RW	RW	RW
x	1	1	RO	n/a	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
 - If [HSTR_EL2.T9](#)==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and $SCR_EL3.NS == 1$:
 - If $MDCR_EL2.TPM == 1$, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \&\& (HCR_EL2.E2H == 1) \&\& (HCR_EL2.TGE == 0)$:
 - If $HSTR_EL2.T9 == 1$, Non-secure write accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $HDCR.TPM == 1$, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.
 - If $HSTR.T9 == 1$, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.
- When EL3 is implemented and is using AArch64:
 - If $MDCR_EL3.TPM == 1$, accesses to this register from EL0, EL1, and EL2 are trapped to EL3.

G6.4.19 PMXEVNTR, Performance Monitors Selected Event Count Register

The PMXEVNTR characteristics are:

Purpose

Reads or writes the value of the selected event counter, [PMEVCNTR<n>](#). [PMSELR.SEL](#) determines which event counter is selected.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register PMXEVNTR is architecturally mapped to AArch64 System register [PMEVCNTR_ELO](#).

This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMXEVNTR is a 32-bit register.

Field descriptions

The PMXEVNTR bit assignments are:

PMEVCNTR<n>, bits [31:0]

Value of the selected event counter, [PMEVCNTR<n>](#), where n is the value stored in [PMSELR.SEL](#).

Accessing the PMXEVNTR

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c9, c13, 2	000	010	1001	1111	1101

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	RW	RW	n/a	RW
x	0	1	RW	RW	RW	RW
x	1	1	RW	n/a	RW	RW

If `PMSELR.SEL` is greater than or equal to the number of accessible counters then reads and writes of `PMXVCNTR` are CONstrained UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a NOP.
- Accesses to the register behave as if `PMSELR.SEL` has an UNKNOWN value less than the number of counters accessible at the current Exception level and Security state.
- Accesses to the register behave as if `PMSELR.SEL` is 31.
- In Non-secure state, for an access from PL1 or a permitted access from PL0, if `PMSELR.SEL`, or `PMSELR_EL0.SEL` if EL1 is using AArch64, is greater than or equal to the number of accessible counters but is less than the number of implemented counters, the register access is trapped to EL2. Accesses from PL0 are permitted when:
 - EL1 is using AArch32 and the value of `PMUSERENR.EN` is 1.
 - EL1 is using AArch64 and the value of `PMUSERENR_EL0.EN` is 1.

Note

In an implementation that includes EL2, in Non-secure state at EL0 and EL1:

- If EL2 is using AArch32, `HDCR.HPMN` identifies the number of accessible counters.
- If EL2 is using AArch64, `MDCR_EL2.HPMN` identifies the number of accessible counters.

Otherwise, the number of accessible counters is the number of implemented counters.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- In both security states, and not dependent on other bits:
 - If `PMUSERENR.EN`==0, and `PMUSERENR.ER`==0, read accesses to this register from EL0 are trapped to Undefined mode.
 - If `PMUSERENR.EN`==0, write accesses to this register from EL0 are trapped to Undefined mode.
 - If `PMUSERENR_EL0.EN`==0, and `PMUSERENR_EL0.ER`==0, read accesses to this register from EL0 are trapped to EL1.
 - If `PMUSERENR_EL0.EN`==0, write accesses to this register from EL0 are trapped to EL1.

- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 0)$:
 - If $HSTR_EL2.T9 == 1$, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and $SCR_EL3.NS == 1$:
 - If $MDCR_EL2.TPM == 1$, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 1) \ \&\& \ (HCR_EL2.TGE == 0)$:
 - If $HSTR_EL2.T9 == 1$, Non-secure write accesses to this register from EL0 and EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $HDCR.TPM == 1$, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.
 - If $HSTR.T9 == 1$, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.
- When EL3 is implemented and is using AArch64:
 - If $MDCR_EL3.TPM == 1$, accesses to this register from EL0, EL1, and EL2 are trapped to EL3.

G6.4.20 PMXEVTYPER, Performance Monitors Selected Event Type Register

The PMXEVTYPER characteristics are:

Purpose

When `PMSELR.SEL` selects an event counter, this accesses a `PMEVTYPER<n>` register. When `PMSELR.SEL` selects the cycle counter, this accesses `PMCCFILTR`.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register `PMXEVTYPER` is architecturally mapped to AArch64 System register `PMXEVTYPER_ELO`.

When the value of `PMSELR.SEL` is 31, to select the cycle counter, RW fields in this register have defined reset values that apply only when the PE resets into an Exception level that is using AArch32. See `PMCCFILTR` for the reset values.

Otherwise, RW fields in this register reset to IMPLEMENTATION DEFINED values that might be UNKNOWN. This applies whenever `PMSELR.SEL` selects an event counter.

Attributes

`PMXEVTYPER` is a 32-bit register.

Field descriptions

The `PMXEVTYPER` bit assignments are:

Bits [31:0]

Event type register or `PMCCFILTR`.

When `PMSELR.SEL` = 31, this register accesses `PMCCFILTR`.

Otherwise, this register accesses `PMEVTYPER<n>` where `n` is the value in `PMSELR.SEL`.

Accessing the PMXEVTYPER

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c9, c13, 1	000	001	1001	1111	1101

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	RW	RW	n/a	RW
x	0	1	RW	RW	RW	RW
x	1	1	RW	n/a	RW	RW

If `PMSELR.SEL` is greater than or equal to the number of accessible counters then reads and writes of `PMXEVTYPER` are **CONSTRAINED UNPREDICTABLE**, and the following behaviors are permitted:

- Accesses to the register are **UNDEFINED**.
- Accesses to the register behave as **RAZ/WI**.
- Accesses to the register execute as a **NOP**.
- Accesses to the register behave as if `PMSELR.SEL` has an **UNKNOWN** value less than the number of counters accessible at the current Exception level and Security state.
- Accesses to the register behave as if `PMSELR.SEL` is 31.
- In Non-secure state, for an access from PL1 or a permitted access from PL0, if `PMSELR.SEL`, or `PMSELR_EL0.SEL` if EL1 is using AArch64, is greater than or equal to the number of accessible counters but is less than the number of implemented counters, the register access is trapped to EL2. Accesses from PL0 are permitted when:
 - EL1 is using AArch32 and the value of `PMUSERENR.EN` is 1.
 - EL1 is using AArch64 and the value of `PMUSERENR_EL0.EN` is 1.

Note

In an implementation that includes EL2, in Non-secure state at EL0 and EL1:

- If EL2 is using AArch32, `HDCR.HPMN` identifies the number of accessible counters.
- If EL2 is using AArch64, `MDCR_EL2.HPMN` identifies the number of accessible counters.

Otherwise, the number of accessible counters is the number of implemented counters.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- In both security states, and not dependent on other bits:
 - If `PMUSERENR.EN`==0, accesses to this register from EL0 are trapped to Undefined mode.
 - If `PMUSERENR_EL0.EN`==0, accesses to this register from EL0 are trapped to EL1.
- When EL2 is implemented and is using AArch64 and `(SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0)`:
 - If `HSTR_EL2.T9`==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and $SCR_EL3.NS == 1$:
 - If $MDCR_EL2.TPM == 1$, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \&\& (HCR_EL2.E2H == 1) \&\& (HCR_EL2.TGE == 0)$:
 - If $HSTR_EL2.T9 == 1$, Non-secure write accesses to this register from EL0 and EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $HDCR.TPM == 1$, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.
 - If $HSTR.T9 == 1$, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.
- When EL3 is implemented and is using AArch64:
 - If $MDCR_EL3.TPM == 1$, accesses to this register from EL0, EL1, and EL2 are trapped to EL3.

G6.5 Generic Timer registers

This section lists the Generic Timer registers in AArch32.

G6.5.1 CNTFRQ, Counter-timer Frequency register

The CNTFRQ characteristics are:

Purpose

This register is provided so that software can discover the frequency of the system counter. It must be programmed with this value as part of system initialization. The value of the register is not interpreted by hardware.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register CNTFRQ is architecturally mapped to AArch64 System register [CNTFRQ_EL0](#).

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTFRQ is a 32-bit register.

Field descriptions

The CNTFRQ bit assignments are:

Bits [31:0]

Clock frequency. Indicates the system counter clock frequency, in Hz.

Accessing the CNTFRQ

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c14, c0, 0	000	000	1110	1111	0000

Accessibility

The register is accessible in software as follows:

Configuration	Control			Accessibility			
	E2H	TGE	NS	EL0	EL1	EL2	EL3
EL1 is the highest implemented Exception level.	x	x	x	RO	RW	n/a	n/a
EL2 is the highest implemented Exception level.	x	0	1	RO	RO	RW	n/a
EL2 is the highest implemented Exception level.	x	1	1	RO	n/a	RW	n/a
EL3 is the highest implemented Exception level.	x	x	0	RO	RO	RO	RW
EL3 is the highest implemented Exception level.	x	0	1	RO	RO	RO	RW
EL3 is the highest implemented Exception level.	x	1	1	RO	n/a	RO	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When $HCR_EL2.E2H == 0$:
 - If $CNTKCTL_EL1.EL0PCTEN == 0$, and $CNTKCTL_EL1.EL0VCTEN == 0$, read accesses to this register from EL0 are trapped to EL1.
 - If $CNTKCTL.PL0PCTEN == 0$, and $CNTKCTL.PL0VCTEN == 0$, read accesses to this register from EL0 are trapped to Undefined mode.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \&\& (HCR_EL2.E2H == 1) \&\& (HCR_EL2.TGE == 0)$:
 - If $CNTKCTL_EL1.EL0PCTEN == 0$, and $CNTKCTL_EL1.EL0VCTEN == 0$, Non-secure read accesses to this register from EL0 are trapped to EL1.
 - If $CNTKCTL.PL0PCTEN == 0$, and $CNTKCTL.PL0VCTEN == 0$, Non-secure read accesses to this register from EL0 are trapped to Undefined mode.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \&\& (HCR_EL2.E2H == 1) \&\& (HCR_EL2.TGE == 1)$:
 - If $CNTHCTL_EL2.EL0PCTEN == 0$, and $CNTHCTL_EL2.EL0VCTEN == 0$, Non-secure read accesses to this register from EL0 are trapped to EL2.

G6.5.2 CNTHCTL, Counter-timer Hyp Control register

The CNTHCTL characteristics are:

Purpose

Controls the generation of an event stream from the physical counter, and access from Non-secure EL1 modes to the physical counter and the Non-secure EL1 physical timer.

Configurations

AArch32 System register CNTHCTL is architecturally mapped to AArch64 System register [CNTHCTL_EL2](#).

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTHCTL is a 32-bit register.

Field descriptions

The CNTHCTL bit assignments are:

Bits [31:8]

Reserved, RES0.

EVNTI, bits [7:4]

Selects which bit (0 to 15) of the counter register [CNTPCT](#) is the trigger for the event stream generated from that counter, when that stream is enabled.

EVNTDIR, bit [3]

Controls which transition of the counter register [CNTPCT](#) trigger bit, defined by EVNTI, generates an event when the event stream is enabled:

- 0 A 0 to 1 transition of the trigger bit triggers an event.
- 1 A 1 to 0 transition of the trigger bit triggers an event.

EVNTEN, bit [2]

Enables the generation of an event stream from the counter register [CNTPCT](#):

- 0 Disables the event stream.
- 1 Enables the event stream.

PL1PCEN, bit [1]

Traps Non-secure EL0 and EL1 accesses to the physical timer registers to Hyp mode.

- 0 Non-secure EL0 and EL1 accesses to the [CNTP_CTL](#), [CNTP_CVAL](#), and [CNTP_TVAL](#) are trapped to Hyp mode, unless the it is trapped by [CNTKCTL.PL0PTEN](#).

1 This control does not cause any instructions to be trapped.

If EL3 is implemented and EL2 is not implemented, behavior is as if this bit is 1 other than for the purpose of a direct read.

PL1PCTEN, bit [0]

Traps Non-secure EL0 and EL1 accesses to the physical counter register to Hyp mode.

0 Non-secure EL0 and EL1 accesses to the **CNTPCT** are trapped to Hyp mode, unless it is trapped by **CNTKCTL.PL0PCTEN**.

1 This control does not cause any instructions to be trapped.

If EL3 is implemented and EL2 is not implemented, behavior is as if this bit is 1 other than for the purpose of a direct read.

Accessing the CNTHCTL

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 4, <Rt>, c14, c1, 0	100	000	1110	1111	0001

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	-
x	0	1	-	-	RW	RW
x	1	1	-	n/a	RW	RW

G6.5.3 CNTHP_CTL, Counter-timer Hyp Physical Timer Control register

The CNTHP_CTL characteristics are:

Purpose

Control register for the Hyp mode physical timer.

Configurations

AArch32 System register CNTHP_CTL is architecturally mapped to AArch64 System register [CNTHP_CTL_EL2](#).

If EL2 is not implemented, this register is RES0 from EL3.

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into EL2 with EL2 using AArch32, or into EL3 with EL3 using AArch32. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTHP_CTL is a 32-bit register.

Field descriptions

The CNTHP_CTL bit assignments are:

Bits [31:3]

Reserved, RES0.

ISTATUS, bit [2]

The status of the timer. This bit indicates whether the timer condition is met:

- 0 Timer condition is not met.
- 1 Timer condition is met.

When the value of the ENABLE bit is 1, ISTATUS indicates whether the timer condition is met. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0 then the timer interrupt is asserted.

When the value of the ENABLE bit is 0, the ISTATUS field is UNKNOWN.

For more information see [Operation of the CompareValue views of the timers on page D6-2187](#) and [Operation of the TimerValue views of the timers on page D6-2188](#).

This bit is read-only.

This field resets to a value that is architecturally UNKNOWN.

IMASK, bit [1]

Timer interrupt mask bit. Permitted values are:

- 0 Timer interrupt is not masked by the IMASK bit.
- 1 Timer interrupt is masked by the IMASK bit.

For more information, see the description of the ISTATUS bit.

This field resets to a value that is architecturally UNKNOWN.

ENABLE, bit [0]

Enables the timer. Permitted values are:

- 0 Timer disabled.
- 1 Timer enabled.

Setting this bit to 0 disables the timer output signal, but the timer value accessible from [CNTHP_TVAL](#) continues to count down.

———— Note ————

Disabling the output signal might be a power-saving option.

When this register has an architecturally-defined reset value, this field resets to 0.

Accessing the CNTHP_CTL

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 4, <Rt>, c14, c2, 1	100	001	1110	1111	0010
p15, 0, <Rt>, c14, c2, 1	000	001	1110	1111	0010

Accessibility

The register is accessible in software as follows:

<syntax>	Control			Accessibility			
	E2H	TGE	NS	EL0	EL1	EL2	EL3
p15, 4, <Rt>, c14, c2, 1	x	x	0	-	-	n/a	-
p15, 4, <Rt>, c14, c2, 1	x	0	1	-	-	RW	RW
p15, 4, <Rt>, c14, c2, 1	x	1	1	-	n/a	RW	RW

p15, 0, <Rt>, c14, c2, 1	0	1	1	CNTP_CTL	n/a	CNTP_CTL	CNTP_CTL
p15, 0, <Rt>, c14, c2, 1	1	0	1	CNTP_CTL	CNTP_CTL	n/a	n/a
p15, 0, <Rt>, c14, c2, 1	1	1	1	RW	n/a	n/a	n/a

This table applies to all instructions that can access this register.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 1) \ \&\& \ (HCR_EL2.TGE == 1)$:
 - If $CNTHCTL_EL2.EL0PTEN == 0$, Non-secure accesses to this register from EL0 are trapped to EL2.

G6.5.4 CNTHP_CVAL, Counter-timer Hyp Physical CompareValue register

The CNTHP_CVAL characteristics are:

Purpose

Holds the compare value for the Hyp mode physical timer.

Configurations

AArch32 System register CNTHP_CVAL is architecturally mapped to AArch64 System register [CNTHP_CVAL_EL2](#).

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTHP_CVAL is a 64-bit register.

Field descriptions

The CNTHP_CVAL bit assignments are:

CompareValue, bits [63:0]

Holds the EL2 physical timer CompareValue.

When [CNTHP_CTL.ENABLE](#) is 1, the timer condition is met when ([CNTPCT](#) - CompareValue) is greater than zero. This means that CompareValue acts like a 64-bit upcounter timer. When the timer condition is met:

- [CNTHP_CTL.ISTATUS](#) is set to 1.
- If [CNTHP_CTL.IMASK](#) is 0, an interrupt is generated.

When [CNTHP_CTL.ENABLE](#) is 0, the timer condition is not met, but [CNTPCT](#) continues to count.

Accessing the CNTHP_CVAL

This register can be read using MRRC with the following syntax:

MRRC <syntax>

This register can be written using MCRR with the following syntax:

MCRR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	coproc	CRm
p15, 6, <Rt>, <Rt2>, c14	0110	1111	1110
p15, 2, <Rt>, <Rt2>, c14	0010	1111	1110

Accessibility

The register is accessible in software as follows:

<syntax>	Control			Accessibility			
	E2H	TGE	NS	EL0	EL1	EL2	EL3
p15, 6, <Rt>, <Rt2>, c14	x	x	0	-	-	n/a	-
p15, 6, <Rt>, <Rt2>, c14	x	0	1	-	-	RW	RW
p15, 6, <Rt>, <Rt2>, c14	x	1	1	-	n/a	RW	RW
p15, 2, <Rt>, <Rt2>, c14	x	x	0	CNTP_CVAL	CNTP_CVAL	n/a	CNTP_CVAL
p15, 2, <Rt>, <Rt2>, c14	0	0	1	CNTP_CVAL	CNTP_CVAL	CNTP_CVAL	CNTP_CVAL
p15, 2, <Rt>, <Rt2>, c14	0	1	1	CNTP_CVAL	n/a	CNTP_CVAL	CNTP_CVAL
p15, 2, <Rt>, <Rt2>, c14	1	0	1	CNTP_CVAL	CNTP_CVAL	n/a	n/a
p15, 2, <Rt>, <Rt2>, c14	1	1	1	RW	n/a	n/a	n/a

This table applies to all instructions that can access this register.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 1):
 - If CNTHCTL_EL2.ELOPTEN==0, Non-secure accesses to this register from EL0 are trapped to EL2.

G6.5.5 CNTHP_TVAL, Counter-timer Hyp Physical Timer TimerValue register

The CNTHP_TVAL characteristics are:

Purpose

Holds the timer value for the Hyp mode physical timer.

Configurations

AArch32 System register CNTHP_TVAL is architecturally mapped to AArch64 System register [CNTHP_TVAL_EL2](#).

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTHP_TVAL is a 32-bit register.

Field descriptions

The CNTHP_TVAL bit assignments are:

TimerValue, bits [31:0]

The TimerValue view of the EL2 physical timer.

On a read of this register:

- If [CNTHP_CTL.ENABLE](#) is 0, the value returned is UNKNOWN.
- If [CNTHP_CTL.ENABLE](#) is 1, the value returned is ([CNTHP_CVAL](#) - [CNTPCT](#)).

On a write of this register, [CNTHP_CVAL](#) is set to ([CNTPCT](#) + TimerValue), where TimerValue is treated as a signed 32-bit integer.

When [CNTHP_CTL.ENABLE](#) is 1, the timer condition is met when ([CNTPCT](#) - [CNTHP_CVAL](#)) is greater than zero. This means that TimerValue acts like a 32-bit downcounter timer. When the timer condition is met:

- [CNTHP_CTL.ISTATUS](#) is set to 1.
- If [CNTHP_CTL.IMASK](#) is 0, an interrupt is generated.

When [CNTHP_CTL.ENABLE](#) is 0, the timer condition is not met, but [CNTPCT](#) continues to count, so the TimerValue view appears to continue to count down.

Accessing the CNTHP_TVAL

This register can be read using MRC with the following syntax:

```
MRC <syntax>
```

This register can be written using MCR with the following syntax:

```
MCR <syntax>
```

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 4, <Rt>, c14, c2, 0	100	000	1110	1111	0010
p15, 0, <Rt>, c14, c2, 0	000	000	1110	1111	0010

Accessibility

The register is accessible in software as follows:

<syntax>	Control			Accessibility			
	E2H	TGE	NS	EL0	EL1	EL2	EL3
p15, 4, <Rt>, c14, c2, 0	x	x	0	-	-	n/a	-
p15, 4, <Rt>, c14, c2, 0	x	0	1	-	-	RW	RW
p15, 4, <Rt>, c14, c2, 0	x	1	1	-	n/a	RW	RW
p15, 0, <Rt>, c14, c2, 0	x	x	0	CNTP_TVAL	CNTP_TVAL	n/a	CNTP_TVAL
p15, 0, <Rt>, c14, c2, 0	0	0	1	CNTP_TVAL	CNTP_TVAL	CNTP_TVAL	CNTP_TVAL
p15, 0, <Rt>, c14, c2, 0	0	1	1	CNTP_TVAL	n/a	CNTP_TVAL	CNTP_TVAL
p15, 0, <Rt>, c14, c2, 0	1	0	1	CNTP_TVAL	CNTP_TVAL	n/a	n/a
p15, 0, <Rt>, c14, c2, 0	1	1	1	RW	n/a	n/a	n/a

This table applies to all instructions that can access this register.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 1):
 - If CNTHCTL_EL2.EL0PTEN==0, Non-secure accesses to this register from EL0 are trapped to EL2.

G6.5.6 CNTHV_CTL, Counter-timer Virtual Timer Control register (EL2)

The CNTHV_CTL characteristics are:

Purpose

Provides AArch32 access to the control register for the EL2 virtual timer.

Note

The EL2 virtual timer is implemented by [ARMv8.1-VHE](#). It is only accessible from AArch32 state when EL0 is using AArch32, EL2 is using AArch64, and the value of [HCR_EL2](#).{E2H, TGE} is {1, 1}.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register CNTHV_CTL is architecturally mapped to AArch64 System register [CNTHV_CTL_EL2](#).

This register is introduced in ARMv8.1.

Attributes

CNTHV_CTL is a 32-bit register.

Field descriptions

The CNTHV_CTL bit assignments are:

Bits [31:3]

Reserved, RES0.

ISTATUS, bit [2]

The status of the timer. This bit indicates whether the timer condition is met:

- 0 Timer condition is not met.
- 1 Timer condition is met.

When the value of the ENABLE bit is 1, ISTATUS indicates whether the timer condition is met. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0 then the timer interrupt is asserted.

When the value of the ENABLE bit is 0, the ISTATUS field is UNKNOWN.

For more information see [Operation of the CompareValue views of the timers on page D6-2187](#) and [Operation of the TimerValue views of the timers on page D6-2188](#).

This bit is read-only.

IMASK, bit [1]

Timer interrupt mask bit. Permitted values are:

- 0 Timer interrupt is not masked by the IMASK bit.
- 1 Timer interrupt is masked by the IMASK bit.

For more information, see the description of the ISTATUS bit.

ENABLE, bit [0]

Enables the timer. Permitted values are:

- 0 Timer disabled.
- 1 Timer enabled.

Setting this bit to 0 disables the timer output signal, but the timer value accessible from [CNTHV_TVAL](#) continues to count down.

Note

Disabling the output signal might be a power-saving option.

Accessing the CNTHV_CTL

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c14, c3, 1	000	001	1110	1111	0011

This register is accessed using the encoding for [CNTV_CTL](#).

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	CNTV_CTL	CNTV_CTL	n/a	CNTV_CTL
0	0	1	CNTV_CTL	CNTV_CTL	CNTV_CTL	CNTV_CTL
0	1	1	CNTV_CTL	n/a	CNTV_CTL	CNTV_CTL
1	0	1	CNTV_CTL	CNTV_CTL	n/a	n/a
1	1	1	RW	n/a	n/a	n/a

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \ \&\& \ (HCR_EL2.E2H == 1) \ \&\& \ (HCR_EL2.TGE == 1)$:
 - If $CNTHCTL_EL2.EL0VTEN == 0$, Non-secure accesses to this register from EL0 are trapped to EL2.

G6.5.7 CNTHV_CVAL, Counter-timer Virtual Timer CompareValue register (EL2)

The CNTHV_CVAL characteristics are:

Purpose

Provides AArch32 access to the compare value for the EL2 virtual timer.

Note

The EL2 virtual timer is implemented by [ARMv8.1-VHE](#). It is only accessible from AArch32 state when EL0 is using AArch32, EL2 is using AArch64, and the value of [HCR_EL2](#).{E2H, TGE} is {1, 1}.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register CNTHV_CVAL is architecturally mapped to AArch64 System register [CNTHV_CVAL_EL2](#).

This register is introduced in ARMv8.1.

Attributes

CNTHV_CVAL is a 64-bit register.

Field descriptions

The CNTHV_CVAL bit assignments are:

CompareValue, bits [63:0]

Holds the EL2 virtual timer CompareValue.

When [CNTHV_CTL](#).ENABLE is 1, the timer condition is met when ([CNTVCT](#) - CompareValue) is greater than zero. This means that CompareValue acts like a 64-bit upcounter timer. When the timer condition is met:

- [CNTHV_CTL](#).ISTATUS is set to 1.
- If [CNTHV_CTL](#).IMASK is 0, an interrupt is generated.

When [CNTHV_CTL](#).ENABLE is 0, the timer condition is not met, but [CNTVCT](#) continues to count.

Accessing the CNTHV_CVAL

This register can be read using MRRC with the following syntax:

MRRC <syntax>

This register can be written using MCRR with the following syntax:

MCRR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	coproc	CRm
p15, 3, <Rt>, <Rt2>, c14	0011	1111	1110

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	CNTV_CVAL	CNTV_CVAL	n/a	CNTV_CVAL
0	0	1	CNTV_CVAL	CNTV_CVAL	CNTV_CVAL	CNTV_CVAL
0	1	1	CNTV_CVAL	n/a	CNTV_CVAL	CNTV_CVAL
1	0	1	CNTV_CVAL	CNTV_CVAL	n/a	n/a
1	1	1	RW	n/a	n/a	n/a

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 1):
 - If CNTHCTL_EL2.EL0VTEN==0, Non-secure accesses to this register from EL0 are trapped to EL2.

G6.5.8 CNTHV_TVAL, Counter-timer Virtual Timer TimerValue register (EL2)

The CNTHV_TVAL characteristics are:

Purpose

Provides AArch32 access to the timer value for the EL2 virtual timer.

Note

The EL2 virtual timer is implemented by [ARMv8.1-VHE](#). It is only accessible from AArch32 state when EL0 is using AArch32, EL2 is using AArch64, and the value of [HCR_EL2](#).{E2H, TGE} is {1, 1}.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register CNTHV_TVAL is architecturally mapped to AArch64 System register [CNTHV_TVAL_EL2](#).

This register is introduced in ARMv8.1.

Attributes

CNTHV_TVAL is a 32-bit register.

Field descriptions

The CNTHV_TVAL bit assignments are:

TimerValue, bits [31:0]

The TimerValue view of the EL2 virtual timer.

On a read of this register:

- If [CNTHV_CTL.ENABLE](#) is 0, the value returned is UNKNOWN.
- If [CNTHV_CTL.ENABLE](#) is 1, the value returned is $(\text{CNTHV_CVAL} - \text{CNTVCT})$.

On a write of this register, [CNTHV_CVAL](#) is set to $(\text{CNTVCT} + \text{TimerValue})$, where TimerValue is treated as a signed 32-bit integer.

When [CNTHV_CTL.ENABLE](#) is 1, the timer condition is met when $(\text{CNTVCT} - \text{CNTHV_CVAL})$ is greater than zero. This means that TimerValue acts like a 32-bit downcounter timer. When the timer condition is met:

- [CNTV_CTL.ISTATUS](#) is set to 1.
- If [CNTV_CTL.IMASK](#) is 0, an interrupt is generated.

When [CNTV_CTL.ENABLE](#) is 0, the timer condition is not met, but [CNTVCT](#) continues to count, so the TimerValue view appears to continue to count down.

Accessing the CNTHV_TVAL

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c14, c3, 0	000	000	1110	1111	0011

This register is accessed using the encoding for [CNTV_TVAL](#).

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	CNTV_TVAL	CNTV_TVAL	n/a	CNTV_TVAL
0	0	1	CNTV_TVAL	CNTV_TVAL	CNTV_TVAL	CNTV_TVAL
0	1	1	CNTV_TVAL	n/a	CNTV_TVAL	CNTV_TVAL
1	0	1	CNTV_TVAL	CNTV_TVAL	n/a	n/a
1	1	1	RW	n/a	n/a	n/a

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 1):
 - If [CNTHCTL_EL2.EL0VTEN](#)==0, Non-secure accesses to this register from EL0 are trapped to EL2.

G6.5.9 CNTKCTL, Counter-timer Kernel Control register

The CNTKCTL characteristics are:

Purpose

Controls the generation of an event stream from the virtual counter, and access from EL0 modes to the physical counter, virtual counter, EL1 physical timers, and the virtual timer.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register CNTKCTL is architecturally mapped to AArch64 System register [CNTKCTL_EL1](#).

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTKCTL is a 32-bit register.

Field descriptions

The CNTKCTL bit assignments are:

Bits [31:10]

Reserved, RES0.

PL0PTEN, bit [9]

Traps PL0 accesses to the physical timer registers to Undefined mode.

0 PL0 accesses to the [CNTP_CTL](#), [CNTP_CVAL](#), and [CNTP_TVAL](#) registers are trapped to Undefined mode.

1 This control does not cause any instructions to be trapped.

PL0VTEN, bit [8]

Traps PL0 accesses to the virtual timer registers to Undefined mode.

0 PL0 accesses to the [CNTV_CTL](#), [CNTV_CVAL](#), and [CNTV_TVAL](#) registers are trapped to Undefined mode.

1 This control does not cause any instructions to be trapped.

EVNTI, bits [7:4]

Selects which bit (0 to 15) of the counter register [CNTVCT](#) is the trigger for the event stream generated from that counter, when that stream is enabled.

EVNTDIR, bit [3]

Controls which transition of the counter register **CNTVCT** trigger bit, defined by EVNTI, generates an event when the event stream is enabled:

- 0 A 0 to 1 transition of the trigger bit triggers an event.
- 1 A 1 to 0 transition of the trigger bit triggers an event.

EVNTEN, bit [2]

Enables the generation of an event stream from the counter register **CNTVCT**:

- 0 Disables the event stream.
- 1 Enables the event stream.

PL0VCTEN, bit [1]

Traps PL0 accesses to the frequency register and virtual counter register to Undefined mode.

- 0 PL0 accesses to the **CNTVCT** are trapped to Undefined mode.
PL0 accesses to the **CNTFRQ** register are trapped to Undefined mode, if **CNTKCTL.PL0PCTEN** is also 0.
- 1 This control does not cause any instructions to be trapped.

PL0PCTEN, bit [0]

Traps PL0 accesses to the frequency register and physical counter register to Undefined mode.

- 0 PL0 accesses to the **CNTPCT** are trapped to Undefined mode.
PL0 accesses to the **CNTFRQ** register are trapped to Undefined mode, if **CNTKCTL.PL0VCTEN** is also 0.
- 1 This control does not cause any instructions to be trapped.

Accessing the CNTKCTL

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c14, c1, 0	000	000	1110	1111	0001

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	RW	n/a	RW
x	0	1	-	RW	RW	RW
x	1	1	-	n/a	RW	RW

G6.5.10 CNTP_CTL, Counter-timer Physical Timer Control register

The CNTP_CTL characteristics are:

Purpose

Control register for the EL1 physical timer.

Configurations

AArch32 System register CNTP_CTL is architecturally mapped to AArch64 System register [CNTP_CTL_ELO](#).

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into an Exception level that is using AArch32. If the PE resets into EL3 using AArch32 they apply only to the Secure instance of the register. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTP_CTL is a 32-bit register.

Field descriptions

The CNTP_CTL bit assignments are:

Bits [31:3]

Reserved, RES0.

ISTATUS, bit [2]

The status of the timer. This bit indicates whether the timer condition is met:

- 0 Timer condition is not met.
- 1 Timer condition is met.

When the value of the ENABLE bit is 1, ISTATUS indicates whether the timer condition is met. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0 then the timer interrupt is asserted.

When the value of the ENABLE bit is 0, the ISTATUS field is UNKNOWN.

For more information see [Operation of the CompareValue views of the timers on page D6-2187](#) and [Operation of the TimerValue views of the timers on page D6-2188](#).

This bit is read-only.

This field resets to a value that is architecturally UNKNOWN.

IMASK, bit [1]

Timer interrupt mask bit. Permitted values are:

- 0 Timer interrupt is not masked by the IMASK bit.
- 1 Timer interrupt is masked by the IMASK bit.

For more information, see the description of the ISTATUS bit.

This field resets to a value that is architecturally UNKNOWN.

ENABLE, bit [0]

Enables the timer. Permitted values are:

- 0 Timer disabled.
- 1 Timer enabled.

Setting this bit to 0 disables the timer output signal, but the timer value accessible from [CNTP_TVAL](#) continues to count down.

———— Note ————

Disabling the output signal might be a power-saving option.

When this register has an architecturally-defined reset value, this field resets to 0.

Accessing the CNTP_CTL

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c14, c2, 1	000	001	1110	1111	0010

Accessibility

The register is accessible in software as follows:

Configuration	Control			Accessibility				Instance
	E2H	TGE	NS	EL0	EL1	EL2	EL3	
EL3 is not implemented.	x	x	0	RW	RW	n/a	n/a	CNTP_CTL

EL3 is using AArch32.	x	1	1	RW	n/a	RW	RW	CNTP_CTL_ns

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When $HCR_EL2.E2H == 0$:
 - If $CNTKCTL_EL1.EL0PTEN == 0$, accesses to this register from EL0 are trapped to EL1.
 - If $CNTKCTL.PL0PTEN == 0$, accesses to this register from EL0 are trapped to Undefined mode.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \&\& (HCR_EL2.E2H == 0)$:
 - If $CNTHCTL_EL2.EL1PCEN == 0$, Non-secure accesses to this register from EL1 are trapped to EL2.
 - If $CNTHCTL_EL2.EL1PCEN == 0$, and $CNTKCTL_EL1.EL0PTEN == 1$, Non-secure accesses to this register from EL0 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \&\& (HCR_EL2.E2H == 1) \&\& (HCR_EL2.TGE == 0)$:
 - If $CNTHCTL_EL2.EL1PTEN == 0$, Non-secure accesses to this register from EL1 are trapped to EL2.
 - If $CNTHCTL_EL2.EL1PTEN == 0$, and $CNTKCTL_EL1.EL0PTEN == 1$, Non-secure accesses to this register from EL0 are trapped to EL2.
 - If $CNTKCTL_EL1.EL0PTEN == 0$, Non-secure accesses to this register from EL0 are trapped to EL1.
 - If $CNTKCTL.PL0PTEN == 0$, Non-secure accesses to this register from EL0 are trapped to Undefined mode.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \&\& (HCR_EL2.E2H == 1) \&\& (HCR_EL2.TGE == 1)$:
 - If $CNTHCTL_EL2.EL0PTEN == 0$, Non-secure accesses to this register from EL0 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and $SCR_EL3.NS == 1$:
 - If $CNTHCTL.PL1PCEN == 0$, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.

G6.5.11 CNTP_CVAL, Counter-timer Physical Timer CompareValue register

The CNTP_CVAL characteristics are:

Purpose

Holds the compare value for the EL1 physical timer.

Configurations

AArch32 System register CNTP_CVAL is architecturally mapped to AArch64 System register [CNTP_CVAL_EL0](#).

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTP_CVAL is a 64-bit register.

Field descriptions

The CNTP_CVAL bit assignments are:

CompareValue, bits [63:0]

Holds the EL1 physical timer CompareValue.

When [CNTP_CTL.ENABLE](#) is 1, the timer condition is met when ([CNTPCT](#) - CompareValue) is greater than zero. This means that CompareValue acts like a 64-bit upcounter timer. When the timer condition is met:

- [CNTP_CTL.ISTATUS](#) is set to 1.
- If [CNTP_CTL.IMASK](#) is 0, an interrupt is generated.

When [CNTP_CTL.ENABLE](#) is 0, the timer condition is not met, but [CNTPCT](#) continues to count.

Accessing the CNTP_CVAL

This register can be read using MRRC with the following syntax:

MRRC <syntax>

This register can be written using MCRR with the following syntax:

MCRR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	coproc	CRm
p15, 2, <Rt>, <Rt2>, c14	0010	1111	1110

Accessibility

The register is accessible in software as follows:

Configuration	Control			Accessibility				Instance
	E2H	TGE	NS	EL0	EL1	EL2	EL3	
EL3 is using AArch32.	x	x	0	RW	n/a	n/a	RW	CNTP_CVAL_s
EL3 is using AArch32.	x	0	1	RW	RW	RW	RW	CNTP_CVAL_ns
EL3 is using AArch32.	x	1	1	RW	n/a	RW	RW	CNTP_CVAL_ns
EL3 is not implemented.	x	x	0	RW	RW	n/a	n/a	CNTP_CVAL

EL3 is using AArch64.	1	1	1	CNTHP_CVAL	n/a	n/a	n/a	-

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When $HCR_EL2.E2H == 0$:
 - If $CNTKCTL_EL1.EL0PTEN == 0$, accesses to this register from EL0 are trapped to EL1.
 - If $CNTKCTL.PL0PTEN == 0$, accesses to this register from EL0 are trapped to Undefined mode.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \&\& (HCR_EL2.E2H == 0)$:
 - If $CNTHCTL_EL2.EL1PCEN == 0$, Non-secure accesses to this register from EL1 are trapped to EL2.
 - If $CNTHCTL_EL2.EL1PCEN == 0$, and $CNTKCTL_EL1.EL0PTEN == 1$, Non-secure accesses to this register from EL0 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \&\& (HCR_EL2.E2H == 1) \&\& (HCR_EL2.TGE == 0)$:
 - If $CNTHCTL_EL2.EL1PTEN == 0$, Non-secure accesses to this register from EL1 are trapped to EL2.
 - If $CNTHCTL_EL2.EL1PTEN == 0$, and $CNTKCTL_EL1.EL0PTEN == 1$, Non-secure accesses to this register from EL0 are trapped to EL2.
 - If $CNTKCTL_EL1.EL0PTEN == 0$, Non-secure accesses to this register from EL0 are trapped to EL1.
 - If $CNTKCTL.PL0PTEN == 0$, Non-secure accesses to this register from EL0 are trapped to Undefined mode.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 1):
 - If CNTHCTL_EL2.EL0PTEN==0, Non-secure accesses to this register from EL0 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If CNTHCTL.PL1PCEN==0, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.

G6.5.12 CNTP_TVAL, Counter-timer Physical Timer TimerValue register

The CNTP_TVAL characteristics are:

Purpose

Holds the timer value for the EL1 physical timer.

Configurations

AArch32 System register CNTP_TVAL is architecturally mapped to AArch64 System register [CNTP_TVAL_ELO](#).

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTP_TVAL is a 32-bit register.

Field descriptions

The CNTP_TVAL bit assignments are:

TimerValue, bits [31:0]

The TimerValue view of the EL1 physical timer.

On a read of this register:

- If [CNTP_CTL.ENABLE](#) is 0, the value returned is UNKNOWN.
- If [CNTP_CTL.ENABLE](#) is 1, the value returned is ([CNTP_CVAL](#) - [CNTPCT](#)).

On a write of this register, [CNTP_CVAL](#) is set to ([CNTPCT](#) + TimerValue), where TimerValue is treated as a signed 32-bit integer.

When [CNTP_CTL.ENABLE](#) is 1, the timer condition is met when ([CNTPCT](#) - [CNTP_CVAL](#)) is greater than zero. This means that TimerValue acts like a 32-bit downcounter timer. When the timer condition is met:

- [CNTP_CTL.ISTATUS](#) is set to 1.
- If [CNTP_CTL.IMASK](#) is 0, an interrupt is generated.

When [CNTP_CTL.ENABLE](#) is 0, the timer condition is not met, but [CNTPCT](#) continues to count, so the TimerValue view appears to continue to count down.

Accessing the CNTP_TVAL

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c14, c2, 0	000	000	1110	1111	0010

Accessibility

The register is accessible in software as follows:

Configuration	Control			Accessibility				Instance
	E2H	TGE	NS	EL0	EL1	EL2	EL3	
EL3 is not implemented.	x	x	0	RW	RW	n/a	n/a	CNTP_TVAL
EL3 is not implemented.	0	0	1	RW	RW	RW	n/a	CNTP_TVAL
EL3 is not implemented.	0	1	1	RW	n/a	RW	n/a	CNTP_TVAL
EL3 is not implemented.	1	0	1	RW	RW	n/a	n/a	CNTP_TVAL
EL3 is not implemented.	1	1	1	CNTHP_TVAL	n/a	n/a	n/a	-
EL3 is using AArch64.	x	x	0	RW	RW	n/a	n/a	CNTP_TVAL
EL3 is using AArch64.	0	0	1	RW	RW	RW	n/a	CNTP_TVAL
EL3 is using AArch64.	0	1	1	RW	n/a	RW	n/a	CNTP_TVAL
EL3 is using AArch64.	1	0	1	RW	RW	n/a	n/a	CNTP_TVAL
EL3 is using AArch64.	1	1	1	CNTHP_TVAL	n/a	n/a	n/a	-
EL3 is using AArch32.	x	0	1	RW	RW	RW	RW	CNTP_TVAL_ns
EL3 is using AArch32.	x	1	1	RW	n/a	RW	RW	CNTP_TVAL_ns
EL3 is using AArch32.	x	x	0	RW	n/a	n/a	RW	CNTP_TVAL_s

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When $HCR_EL2.E2H == 0$:
 - If $CNTKCTL_EL1.EL0PTEN == 0$, accesses to this register from EL0 are trapped to EL1.
 - If $CNTKCTL.PL0PTEN == 0$, accesses to this register from EL0 are trapped to Undefined mode.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \&\& (HCR_EL2.E2H == 0)$:
 - If $CNTHCTL_EL2.EL1PCEN == 0$, Non-secure accesses to this register from EL1 are trapped to EL2.
 - If $CNTHCTL_EL2.EL1PCEN == 0$, and $CNTKCTL_EL1.EL0PTEN == 1$, Non-secure accesses to this register from EL0 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \&\& (HCR_EL2.E2H == 1) \&\& (HCR_EL2.TGE == 0)$:
 - If $CNTHCTL_EL2.EL1PTEN == 0$, Non-secure accesses to this register from EL1 are trapped to EL2.
 - If $CNTHCTL_EL2.EL1PTEN == 0$, and $CNTKCTL_EL1.EL0PTEN == 1$, Non-secure accesses to this register from EL0 are trapped to EL2.
 - If $CNTKCTL_EL1.EL0PTEN == 0$, Non-secure accesses to this register from EL0 are trapped to EL1.
 - If $CNTKCTL.PL0PTEN == 0$, Non-secure accesses to this register from EL0 are trapped to Undefined mode.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 1):
 - If CNTHCTL_EL2.EL0PTEN==0, Non-secure accesses to this register from EL0 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and SCR_EL3.NS == 1:
 - If CNTHCTL.PL1PCEN==0, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.

G6.5.13 CNTPCT, Counter-timer Physical Count register

The CNTPCT characteristics are:

Purpose

Holds the 64-bit physical count value.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register CNTPCT is architecturally mapped to AArch64 System register [CNTPCT_EL0](#).

Attributes

CNPCT is a 64-bit register.

Field descriptions

The CNTPCT bit assignments are:

Bits [63:0]

Physical count value.

Accessing the CNTPCT

This register can be read using MRRC with the following syntax:

MRRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	coproc	CRm
p15, 0, <Rt>, <Rt2>, c14	0000	1111	1110

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	RO	RO	n/a	RO
x	0	1	RO	RO	RO	RO
x	1	1	RO	n/a	RO	RO

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When $\text{HCR_EL2.E2H} == 0$:
 - If $\text{CNTKCTL_EL1.EL0PCTEN} == 0$, read accesses to this register from EL0 are trapped to EL1.
 - If $\text{CNTKCTL.PL0PCTEN} == 0$, read accesses to this register from EL0 are trapped to Undefined mode.
- When EL2 is implemented and is using AArch64 and $(\text{SCR_EL3.NS} == 1) \ \&\& \ (\text{HCR_EL2.E2H} == 0)$:
 - If $\text{CNTHCTL_EL2.EL1PCTEN} == 0$, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If $\text{CNTHCTL_EL2.EL1PCTEN} == 0$, and $\text{CNTKCTL_EL1.EL0PCTEN} == 1$, Non-secure read accesses to this register from EL0 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and $(\text{SCR_EL3.NS} == 1) \ \&\& \ (\text{HCR_EL2.E2H} == 1) \ \&\& \ (\text{HCR_EL2.TGE} == 0)$:
 - If $\text{CNTHCTL_EL2.EL1PCTEN} == 0$, Non-secure read accesses to this register from EL1 are trapped to EL2.
 - If $\text{CNTHCTL_EL2.EL1PCTEN} == 0$, and $\text{CNTKCTL_EL1.EL0PCTEN} == 1$, Non-secure read accesses to this register from EL0 are trapped to EL2.
 - If $\text{CNTKCTL_EL1.EL0PCTEN} == 0$, Non-secure read accesses to this register from EL0 are trapped to EL1.
 - If $\text{CNTKCTL.PL0PCTEN} == 0$, Non-secure read accesses to this register from EL0 are trapped to Undefined mode.
- When EL2 is implemented and is using AArch64 and $(\text{SCR_EL3.NS} == 1) \ \&\& \ (\text{HCR_EL2.E2H} == 1) \ \&\& \ (\text{HCR_EL2.TGE} == 1)$:
 - If $\text{CNTHCTL_EL2.EL0PCTEN} == 0$, Non-secure read accesses to this register from EL0 are trapped to EL2.
- When EL2 is implemented and is using AArch32 and $\text{SCR_EL3.NS} == 1$:
 - If $\text{CNTHCTL.PL1PCTEN} == 0$, Non-secure read accesses to this register from EL0 and EL1 are trapped to Hyp mode.

G6.5.14 CNTV_CTL, Counter-timer Virtual Timer Control register

The CNTV_CTL characteristics are:

Purpose

Control register for the virtual timer.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register CNTV_CTL is architecturally mapped to AArch64 System register [CNTV_CTL_EL0](#).

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into an Exception level that is using AArch32. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTV_CTL is a 32-bit register.

Field descriptions

The CNTV_CTL bit assignments are:

Bits [31:3]

Reserved, RES0.

ISTATUS, bit [2]

The status of the timer. This bit indicates whether the timer condition is met:

- 0 Timer condition is not met.
- 1 Timer condition is met.

When the value of the ENABLE bit is 1, ISTATUS indicates whether the timer condition is met. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0 then the timer interrupt is asserted.

When the value of the ENABLE bit is 0, the ISTATUS field is UNKNOWN.

For more information see [Operation of the CompareValue views of the timers on page D6-2187](#) and [Operation of the TimerValue views of the timers on page D6-2188](#).

This bit is read-only.

This field resets to a value that is architecturally UNKNOWN.

IMASK, bit [1]

Timer interrupt mask bit. Permitted values are:

- 0 Timer interrupt is not masked by the IMASK bit.
- 1 Timer interrupt is masked by the IMASK bit.

For more information, see the description of the ISTATUS bit.

This field resets to a value that is architecturally UNKNOWN.

ENABLE, bit [0]

Enables the timer. Permitted values are:

- 0 Timer disabled.
- 1 Timer enabled.

Setting this bit to 0 disables the timer output signal, but the timer value accessible from [CNTV_TVAL](#) continues to count down.

Note

Disabling the output signal might be a power-saving option.

When this register has an architecturally-defined reset value, this field resets to 0.

Accessing the CNTV_CTL

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c14, c3, 1	000	001	1110	1111	0011

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	RW	RW	n/a	RW
0	0	1	RW	RW	RW	RW
0	1	1	RW	n/a	RW	RW
1	0	1	RW	RW	n/a	n/a
1	1	1	CNTHV_CTL	n/a	n/a	n/a

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When HCR_EL2.E2H == 0:
 - If CNTKCTL_EL1.EL0VTEN==0, accesses to this register from EL0 are trapped to EL1.
 - If CNTKCTL.PL0VTEN==0, accesses to this register from EL0 are trapped to Undefined mode.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
 - If `CNTKCTL_EL1.EL0VTEN==0`, Non-secure accesses to this register from EL0 are trapped to EL1.
 - If `CNTKCTL.PL0VTEN==0`, Non-secure accesses to this register from EL0 are trapped to Undefined mode.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 1):
 - If `CNTHCTL_EL2.EL0VTEN==0`, Non-secure accesses to this register from EL0 are trapped to EL2.

G6.5.15 CNTV_CVAL, Counter-timer Virtual Timer CompareValue register

The CNTV_CVAL characteristics are:

Purpose

Holds the compare value for the virtual timer.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register CNTV_CVAL is architecturally mapped to AArch64 System register [CNTV_CVAL_EL0](#).

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTV_CVAL is a 64-bit register.

Field descriptions

The CNTV_CVAL bit assignments are:

CompareValue, bits [63:0]

Holds the EL1 virtual timer CompareValue.

When [CNTV_CTL.ENABLE](#) is 1, the timer condition is met when ([CNTVCT](#) - CompareValue) is greater than zero. This means that CompareValue acts like a 64-bit upcounter timer. When the timer condition is met:

- [CNTV_CTL.ISTATUS](#) is set to 1.
- If [CNTV_CTL.IMASK](#) is 0, an interrupt is generated.

When [CNTV_CTL.ENABLE](#) is 0, the timer condition is not met, but [CNTVCT](#) continues to count.

Accessing the CNTV_CVAL

This register can be read using MRRC with the following syntax:

MRRC <syntax>

This register can be written using MCRR with the following syntax:

MCRR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	coproc	CRm
p15, 3, <Rt>, <Rt2>, c14	0011	1111	1110

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	RW	RW	n/a	RW
0	0	1	RW	RW	RW	RW
0	1	1	RW	n/a	RW	RW
1	0	1	RW	RW	n/a	n/a
1	1	1	CNTHV_CVAL	n/a	n/a	n/a

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-4344 for exceptions taken to AArch32 state and *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When $\text{HCR_EL2.E2H} == 0$:
 - If $\text{CNTKCTL_EL1.EL0VTEN} == 0$, accesses to this register from EL0 are trapped to EL1.
 - If $\text{CNTKCTL.PL0VTEN} == 0$, accesses to this register from EL0 are trapped to Undefined mode.
- When EL2 is implemented and is using AArch64 and $(\text{SCR_EL3.NS} == 1) \ \&\& \ (\text{HCR_EL2.E2H} == 1) \ \&\& \ (\text{HCR_EL2.TGE} == 0)$:
 - If $\text{CNTKCTL_EL1.EL0VTEN} == 0$, Non-secure accesses to this register from EL0 are trapped to EL1.
 - If $\text{CNTKCTL.PL0VTEN} == 0$, Non-secure accesses to this register from EL0 are trapped to Undefined mode.
- When EL2 is implemented and is using AArch64 and $(\text{SCR_EL3.NS} == 1) \ \&\& \ (\text{HCR_EL2.E2H} == 1) \ \&\& \ (\text{HCR_EL2.TGE} == 1)$:
 - If $\text{CNTHCTL_EL2.EL0VTEN} == 0$, Non-secure accesses to this register from EL0 are trapped to EL2.

G6.5.16 CNTV_TVAL, Counter-timer Virtual Timer TimerValue register

The CNTV_TVAL characteristics are:

Purpose

Holds the timer value for the virtual timer.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register CNTV_TVAL is architecturally mapped to AArch64 System register [CNTV_TVAL_ELO](#).

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTV_TVAL is a 32-bit register.

Field descriptions

The CNTV_TVAL bit assignments are:

TimerValue, bits [31:0]

The TimerValue view of the virtual timer.

On a read of this register:

- If [CNTV_CTL.ENABLE](#) is 0, the value returned is UNKNOWN.
- If [CNTV_CTL.ENABLE](#) is 1, the value returned is $(\text{CNTV_CVAL} - (\text{CNTPCT} - \text{CNTVOFF}))$.

On a write of this register, [CNTV_CVAL](#) is set to $(\text{CNTPCT} + \text{TimerValue})$, where TimerValue is treated as a signed 32-bit integer.

When [CNTP_CTL.ENABLE](#) is 1, the timer condition is met when $(\text{CNTPCT} - \text{CNTP_CVAL})$ is greater than zero. This means that TimerValue acts like a 32-bit downcounter timer. When the timer condition is met:

- [CNTV_CTL.ISTATUS](#) is set to 1.
- If [CNTV_CTL.IMASK](#) is 0, an interrupt is generated.

When [CNTV_CTL.ENABLE](#) is 0, the timer condition is not met, but [CNTVCT](#) continues to count, so the TimerValue view appears to continue to count down.

Accessing the CNTV_TVAL

This register can be read using MRC with the following syntax:

MRC <syntax>

This register can be written using MCR with the following syntax:

MCR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	opc2	CRn	coproc	CRm
p15, 0, <Rt>, c14, c3, 0	000	000	1110	1111	0011

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	RW	RW	n/a	RW
0	0	1	RW	RW	RW	RW
0	1	1	RW	n/a	RW	RW
1	0	1	RW	RW	n/a	n/a
1	1	1	CNTHV_TVAL	n/a	n/a	n/a

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-4344](#) for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When $HCR_EL2.E2H == 0$:
 - If $CNTKCTL_EL1.EL0VTEN == 0$, accesses to this register from EL0 are trapped to EL1.
 - If $CNTKCTL.PL0VTEN == 0$, accesses to this register from EL0 are trapped to Undefined mode.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \&\& (HCR_EL2.E2H == 1) \&\& (HCR_EL2.TGE == 0)$:
 - If $CNTKCTL_EL1.EL0VTEN == 0$, Non-secure accesses to this register from EL0 are trapped to EL1.
 - If $CNTKCTL.PL0VTEN == 0$, Non-secure accesses to this register from EL0 are trapped to Undefined mode.
- When EL2 is implemented and is using AArch64 and $(SCR_EL3.NS == 1) \&\& (HCR_EL2.E2H == 1) \&\& (HCR_EL2.TGE == 1)$:
 - If $CNTHCTL_EL2.EL0VTEN == 0$, Non-secure accesses to this register from EL0 are trapped to EL2.

G6.5.17 CNTVCT, Counter-timer Virtual Count register

The CNTVCT characteristics are:

Purpose

Holds the 64-bit virtual count value. The virtual count value is equal to the physical count value visible in [CNTPCT](#) minus the virtual offset visible in [CNTVOFF](#).

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register CNTVCT is architecturally mapped to AArch64 System register [CNTVCT_EL0](#).

The value of this register is the same as the value of [CNTPCT](#) in the following conditions:

- When EL2 is not implemented.
- When EL2 is implemented and is using AArch64, [HCR_EL2](#).{E2H, TGE} is {1, 1}, and this register is read from Non-secure EL0.

Attributes

CNTVCT is a 64-bit register.

Field descriptions

The CNTVCT bit assignments are:

Bits [63:0]

Virtual count value.

Accessing the CNTVCT

This register can be read using MRRC with the following syntax:

MRRC <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	coproc	CRm
p15, 1, <Rt>, <Rt2>, c14	0001	1111	1110

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	RO	RO	n/a	RO
x	0	1	RO	RO	RO	RO
x	1	1	RO	n/a	RO	RO

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state](#) on page G1-4344 for exceptions taken to AArch32 state and [Synchronous exception prioritization for exceptions taken to AArch64](#) on page D1-1827 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- When $\text{HCR_EL2.E2H} == 0$:
 - If $\text{CNTKCTL.PL0VCTEN} == 0$, read accesses to this register from EL0 are trapped to Undefined mode.
 - If $\text{CNTKCTL_EL1.EL0VCTEN} == 0$, read accesses to this register from EL0 are trapped to EL1.
- When EL2 is implemented and is using AArch64 and $(\text{SCR_EL3.NS} == 1) \ \&\& \ (\text{HCR_EL2.E2H} == 1) \ \&\& \ (\text{HCR_EL2.TGE} == 0)$:
 - If $\text{CNTKCTL.PL0VCTEN} == 0$, Non-secure read accesses to this register from EL0 are trapped to Undefined mode.
 - If $\text{CNTKCTL_EL1.EL0VCTEN} == 0$, Non-secure read accesses to this register from EL0 are trapped to EL1.
- When EL2 is implemented and is using AArch64 and $(\text{SCR_EL3.NS} == 1) \ \&\& \ (\text{HCR_EL2.E2H} == 1) \ \&\& \ (\text{HCR_EL2.TGE} == 1)$:
 - If $\text{CNTHCTL_EL2.EL0PCTEN} == 0$, Non-secure read accesses to this register from EL0 are trapped to EL2.

G6.5.18 CNTVOFF, Counter-timer Virtual Offset register

The CNTVOFF characteristics are:

Purpose

Holds the 64-bit virtual offset. This is the offset between the physical count value visible in CNTPCT and the virtual count value visible in CNTVCT.

Configurations

AArch32 System register CNTVOFF is architecturally mapped to AArch64 System register CNTVOFF_EL2.

If EL2 is not implemented, this register is RES0 from EL3 and the virtual counter uses a fixed virtual offset of zero.

———— **Note** —————

When EL2 is implemented and is using AArch64, if HCR_EL2.{E2H, TGE} is {1, 1}, the virtual counter uses a fixed virtual offset of zero when CNTVCT is read from Non-secure EL0.

When EL2 is implemented and can use AArch32, on a reset into an Exception level that is using AArch32 this register resets to an IMPLEMENTATION DEFINED value that might be UNKNOWN.

Attributes

CNTVOFF is a 64-bit register.

Field descriptions

The CNTVOFF bit assignments are:

Bits [63:0]

Virtual offset.

Accessing the CNTVOFF

This register can be read using MRRC with the following syntax:

MRRC <syntax>

This register can be written using MCRR with the following syntax:

MCRR <syntax>

This syntax is encoded with the following settings in the instruction encoding:

<syntax>	opc1	coproc	CRm
p15, 4, <Rt>, <Rt2>, c14	0100	1111	1110

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	-
x	0	1	-	-	RW	RW
x	1	1	-	n/a	RW	RW

Part H

External Debug

Chapter H1

About External Debug

This chapter gives an overview of ARMv8 external debug, and specifies the required debug authentication. It contains the following sections:

- [Introduction to external debug](#) on page H1-5430.
- [External debug](#) on page H1-5431.
- [Required debug authentication](#) on page H1-5432.

———— **Note** —————

For information about self-hosted debug, see [Chapter D2 AArch64 Self-hosted Debug](#) and [Chapter G2 AArch32 Self-hosted Debug](#).

H1.1 Introduction to external debug

ARMv8 supports both:

Self-hosted debug

The PE itself hosts a debugger. That is, developers developing software to run on the PE use debugger software running on the same PE.

External debug

The debugger is external to the PE. The debugging might be either on-chip, for example in a second PE, or off-chip, for example a JTAG debugger. External debug is particularly useful for:

- Hardware bring-up. That is, debugging during development when a system is first powered up and not all of the software functionality is available.
- PEs that are deeply embedded inside systems.

To support external debug, the ARM architecture defines required features that are called *external debug features*.

H1.1.1 Definition of a debugger in the context of external debug

When the description of external debug in this Part of the manual describes a *debugger* as controlling external debug this debugger might be a second on-chip PE or an off-chip device such as a JTAG debugger.

H1.2 External debug

Debug events allow an external debugger to halt the PE. ARMv8 provides the following debug events:

- [Halting Step debug events on page H3-5476:](#)
 - The debugger can use this resource to make the PE step through code one line at a time.
- [Halt Instruction debug event on page H3-5486:](#)
 - This might occur when software executes the Halting breakpoint instruction, HLT.
- [Exception Catch debug event on page H3-5487:](#)
 - This can be programmed to occur on all entries to a given Exception level.
- [External Debug Request debug event on page H3-5490:](#)
 - An embedded cross-trigger can signal this debug event.
- [OS Unlock Catch debug event on page H3-5491:](#)
 - This might occur when the state of the OS Lock changes from locked to unlocked.
- [Reset Catch debug events on page H3-5492:](#)
 - This might occur when the PE exits reset state.
- [Software Access debug event on page H3-5493:](#)
 - This can be programmed to occur when software tries to access the Breakpoint Value registers, the Breakpoint Control registers, the Watchpoint value registers, or the Watchpoint Control registers. It caused a trap to Debug state.

Breakpoints and watchpoints can also halt the PE.

When the PE is in Debug state:

- It stops executing instructions from the location indicated by the program counter, and is instead controlled through the external debug interface.
- The *Instruction Transfer Register*, ITR, passes instructions to the PE to execute in Debug state:
 - The ITR contains a single register, EDITR, and associated flow-control flags.
- The *Debug Communications Channel*, DCC, passes data between the PE and the debugger:
 - The DCC includes the data transfer registers, DTRRX and DTRTX, and associated flow-control flags.
 - Although the DCC is an essential part of Debug state operation, it can also be used in Non-debug state.
- The PE cannot service any interrupts in Debug state.

[Chapter H2 Debug State](#) describes Debug state in more detail.

H1.3 Required debug authentication

Any implementation must provide the debug authentication defined in this section, that controls:

- Whether the PE can halt.
- Whether non-invasive debug is permitted.
- Some legacy aspects of the AArch32 self-hosted debug model.

The pseudocode functions shown in [Table H1-1](#), and the conditions that follow that table, define the architectural requirements for debug authentication.

Table H1-1 Debug authentication functions

Pseudocode function	Description
ExternalSecureNoninvasiveDebugEnabled()	Returns TRUE if Secure non-invasive debug is enabled.
AArch32.SelfHostedSecurePrivilegedInvasiveDebugEnabled()	Returns TRUE if Secure invasive self-hosted debug is enabled in AArch32 state.
ExternalSecureInvasiveDebugEnabled()	Returns TRUE if Secure invasive debug is enabled.
ExternalNoninvasiveDebugEnabled()	Returns TRUE if Non-secure non-invasive debug is enabled.
ExternalInvasiveDebugEnabled()	Returns TRUE if Non-secure invasive debug is enabled.

The following conditions always apply:

- if [ExternalInvasiveDebugEnabled\(\)](#) is FALSE then [ExternalSecureInvasiveDebugEnabled\(\)](#) is FALSE.
- if [ExternalNoninvasiveDebugEnabled\(\)](#) is FALSE then [ExternalSecureNoninvasiveDebugEnabled\(\)](#) is FALSE.
- if [ExternalInvasiveDebugEnabled\(\)](#) is TRUE then [ExternalNoninvasiveDebugEnabled\(\)](#) is TRUE.
- if [ExternalSecureInvasiveDebugEnabled\(\)](#) is TRUE then [ExternalSecureNoninvasiveDebugEnabled\(\)](#) is TRUE.

ARM recommends the use of the interface described in [Recommended authentication interface on page K2-6140](#) to provide this debug authentication. The pseudocode functions in [Chapter J1 ARMv8 Pseudocode](#), that are linked to by the entries in the [Pseudocode function](#) column of [Table H1-1](#), assume that this interface is implemented.

Chapter H2

Debug State

This chapter describes Debug state. It contains the following sections:

- [About Debug state on page H2-5434.](#)
- [Halting the PE on debug events on page H2-5435.](#)
- [Entering Debug state on page H2-5442.](#)
- [Behavior in Debug state on page H2-5445.](#)
- [Exiting Debug state on page H2-5471.](#)

———— **Note** —————

[Table K11-1 on page K11-6282](#) disambiguates the general register references used in this chapter.

H2.1 About Debug state

In external debug, debug events allow an external debugger to halt the PE. The PE then enters Debug state. When the PE is in Debug state:

- It stops executing instructions from the location indicated by the program counter, and is instead controlled through the external debug interface.
- The *Instruction Transfer Register*, ITR, passes instructions to the PE to execute in Debug state.
- The *Debug Communications Channel*, DCC, passes data between the PE and the debugger.

The PE cannot service any interrupts in Debug state.

H2.2 Halting the PE on debug events

For details of debug events, see [Introduction to Halting debug events on page H3-5474](#) and [Breakpoint and Watchpoint debug events on page H2-5436](#).

On a debug event, the PE must do one of the following:

- Enter Debug state.
- Pend the debug event.
- Generate a debug exception.
- Ignore the debug event.

This behavior depends on both:

- Whether halting is allowed by the current state of the debug authentication interface. See [Halting allowed and halting prohibited](#).
- The type of debug event and the programming of the debug control registers.
 - See [Halting debug events](#) for all Halting debug events.
 - See [Breakpoint and Watchpoint debug events on page H2-5436](#) for Breakpoint and Watchpoint debug events.

See also [Other debug exceptions on page H2-5437](#).

This means that behavior can be CONSTRAINED UNPREDICTABLE if the conditions change. See [Synchronization and Halting debug events on page H3-5494](#).

[Summary of debug events and possible outcomes on page H3-5474](#) summarizes the possible outcomes of each type of debug event.

H2.2.1 Halting allowed and halting prohibited

Halting can be either allowed or prohibited:

- Halting is always prohibited in Debug state.
- Halting is always prohibited when `DoubleLockStatus() == TRUE`.
 - This means that OS Double Lock is locked.
- Halting is also controlled by the IMPLEMENTATION DEFINED authentication interface, and is prohibited when either:
 - The PE is in Non-secure state and `ExternalInvasiveDebugEnabled() == FALSE`.
 - The PE is in Secure state and `ExternalSecureInvasiveDebugEnabled() == FALSE`.

———— **Note** ————

See [Appendix K2 Recommended External Debug Interface](#) for more information on these functions.

- Otherwise, halting is allowed.

See

- [Pseudocode description of Halting on debug events on page H2-5441](#)
- [Required debug authentication on page H1-5432](#).

H2.2.2 Halting debug events

The Halting debug events are described in [Chapter H3 Halting Debug Events](#).

When a Halting debug event is generated, it causes entry to Debug state if all of:

- Halting is allowed. See [Halting allowed and halting prohibited on page H2-5435](#).
- The Halting debug event is one of:
 - A Halt Instruction debug event and `EDSCR.HDE == 1`.
 - A Software Access debug event and `OSLSR_EL1.OSLK == 0`, meaning that the OS Lock is unlocked.
 - Neither a Halt Instruction debug event nor a Software Access debug event.

———— **Note** —————

- A Halt Instruction debug event is the only Halting debug event that relies on `EDSCR.HDE == 1`.
- Halting on Breakpoint and Watchpoint debug events is also controlled by `EDSCR.HDE`. See [Breakpoint and Watchpoint debug events](#).
- `EDSCR.HDE` can be written by software when the OS Lock is locked. Privileged code can use `SDCR.TDOSA` and `HDCR.TDOSA` to trap writes to these registers.

If a Halting debug event does not generate entry to Debug state because the conditions listed in this section do not hold, then:

- If the Halting debug event is a Halt Instruction debug event, the instruction that generated the Halting debug event is treated as UNDEFINED.
- If the Halting debug event is an Exception Catch debug event or a Software Access debug event, it is ignored.

In all other cases the Halting debug event is pended, see [Pending Halting debug events on page H3-5494](#).

[Summary of actions from debug events on page H2-5439](#) summarizes the possible outcome for each type of Debug event.

———— **Note** —————

Halting debug events never generate debug exceptions.

H2.2.3 Breakpoint and Watchpoint debug events

A breakpoint or watchpoint generates an entry to Debug state if all of the following conditions hold:

- Halting debug is enabled, that is `EDSCR.HDE == 1`.
- Halting is allowed. See [Halting allowed and halting prohibited on page H2-5435](#).
- The OS Lock is unlocked, that is `OSLSR.OSLK == 0`.

The Address Mismatch breakpoint type is reserved when all of these conditions are met.

`MDSCR_EL1.MDE` or `DBGDSCRext.MDBGen` is ignored when determining whether to enter Debug state. A breakpoint or watchpoint that generates entry to Debug state is a Breakpoint or Watchpoint debug event and does not generate a debug exception.

A breakpoint or watchpoint that does not generate an entry to Debug state either:

- Generates a Breakpoint or Watchpoint exception.
- Is ignored.

———— **Note** —————

`EDSCR.HDE` is ignored when determining whether to generate a debug exception. The debug exception is suppressed only if the PE enters Debug state. This means that the use of Halting debug mode in Non-secure state does not affect the Exception model in Secure state.

See [Chapter D2 AArch64 Self-hosted Debug](#), [Chapter G2 AArch32 Self-hosted Debug](#), and the Note in [Other debug exceptions on page H2-5437](#).

H2.2.4 Other debug exceptions

The following events never generate entry to Debug state:

- Breakpoint Instruction exceptions.
- Software Step exceptions.
- Vector Catch exceptions.

The behavior of these events is unchanged when Halting debug mode is enabled, that is when `EDSCR.HDE == 1`. This means that these events can do one of the following:

- They can generate a debug exception.
- They can be ignored.

For additional information, see [Chapter D2 AArch64 Self-hosted Debug](#) and [Chapter G2 AArch32 Self-hosted Debug](#).

H2.2.5 Debug state entry and debug event prioritization

The following are synchronous debug events:

- Breakpoint debug event.
- Watchpoint debug event.
- Halting Step debug event.
- Halt Instruction debug event.
- Exception Catch debug event.
- Software Access debug event.
- Reset Catch debug event.

Each of these synchronous debug events are treated as a synchronous exception generated by an instruction, or by the taking of an exception or reset. That is, if halting is allowed, the synchronous debug event must be taken before any subsequent instructions are executed. Reset Catch debug events must be taken before the PE executes the instruction at the reset vector.

Note

- Reset Catch and Exception Catch debug events might be generated asynchronously, because they can result from an asynchronous exception. However, if halting is allowed after the reset or asynchronous exception has been processed, the Reset Catch or Exception Catch debug event is taken synchronously.
- The Halting Step debug event is generated by the instruction after the stepped instruction. Therefore, if the stepped instruction generates any other synchronous exceptions or debug events these are taken first.

If halting is prohibited then Halting Step debug events and Reset Catch debug events might be pended and taken asynchronously. OS Unlock Catch debug events are always pended and taken asynchronously. See [Pending Halting debug events on page H3-5494](#).

The architecture does not define when asynchronous debug events are taken, and therefore the prioritization of asynchronous debug events is IMPLEMENTATION DEFINED. See [Synchronization and Halting debug events on page H3-5494](#).

The following list shows how the synchronous debug events are prioritized, with -2 being the highest priority.

Note

The priority numbering is the same as the numbering for AArch64 synchronous exception priorities listed in [Synchronous exception types, routing and priorities on page D1-1826](#), and in particular [Prioritization and recognition of interrupts on page D1-1841](#). The Debug events in this section with a negative priority are a higher priority than any synchronous exception. The debug events with fractional priorities have a priority between two or more exceptions. This numbering has no global significance and, for example, does not correlate with the equivalent AArch32 list in [Exception prioritization for exceptions taken to AArch32 state on page G1-4344](#).

The priority for synchronous debug events is as follows:

- 2 Reset Catch debug event. See [Reset Catch debug events on page H3-5492](#).
This debug event has a higher priority than the synchronous exceptions listed in [Synchronous exception types, routing and priorities on page D1-1826](#).
- 1 Exception Catch debug event. See [Exception Catch debug event on page H3-5487](#).
This debug event can be assigned one of two priorities. When it has a priority of -1, it has a higher priority than the synchronous exceptions listed in the Exception model. See [Exception Catch debug event on page H3-5487](#).
- 0 Halting Step debug event. See [Halting Step debug events on page H3-5476](#).
This debug event has a higher priority than the synchronous exceptions listed in the Exception model.
- 1 Software Step debug event. See [Software Step exceptions on page D2-1956](#).
- 1.5 Exception Catch debug event. See [Exception Catch debug event on page H3-5487](#).
This debug event can be assigned one of two priorities, -1 or 1.5. See [Exception Catch debug event on page H3-5487](#).
- 2 - 3 These events are not debug events.
- 4 Breakpoint exception or debug event or Address Matching Vector Catch exception. See [Breakpoint exceptions on page D2-1921](#), and [Vector Catch exceptions on page G2-4510](#).
These two debug events have the same priority.
- 5 - 13 These events are not debug events.
- 14 Halt Instruction debug event. See [Halt Instruction debug event on page H3-5486](#).
- 15 - 19 These events are not debug events.
- 19.5 Software Access debug event. See [Software Access debug event on page H3-5493](#).
- 20 - 21 These events are not debug events.
- 22 Watchpoint exception or debug event. See [Watchpoint exceptions on page D2-1940](#) for exceptions taken from AArch64 state, or [Watchpoint exceptions on page G2-4496](#) for exceptions taken from AArch32 state.
- 23 This event is not a debug event.

For Reset Catch debug events and Halting Step debug events the priorities listed in this section only apply when halting is allowed at the time the event is generated. This means that the event is taken synchronously and not pending.

For more information on the prioritization of exceptions see:

- [Synchronous exception types, routing and priorities on page D1-1826](#).
- [Prioritization and recognition of interrupts on page D1-1841](#).
- [Exception prioritization for exceptions taken to AArch32 state on page G1-4344](#).
- This section covers synchronous and asynchronous exceptions.

Breakpoint debug events and Vector Catch exception

An Address Matching Vector Catch exception has the same priority as a Breakpoint debug event. See [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1827](#).

The prioritization of these events is unchanged even if the breakpoint generates entry to Debug state instead of a Breakpoint exception. This means that if a single instruction generates both an Address Matching Vector Catch exception and a Breakpoint debug event, there is a CONSTRAINED UNPREDICTABLE choice of:

- The PE entering Debug state due to the Breakpoint debug event.
- A Vector Catch exception.

This only applies if all of the following are true:

- Halting debug is enabled.
- Halting is allowed.
- The OS Lock is unlocked.

An Exception Trapping Vector Catch exception must be generated immediately following the exception that generated it. This means that it does not appear in the priority table.

H2.2.6 Imprecise entry to Debug state

Entry to Debug state is normally precise, meaning that the PE cannot enter Debug state if it can neither complete nor abandon all currently executing instructions and leave the PE in a precise state.

A debugger can write a value of 1 to [EDRCCR.CBRRQ](#) to allow imprecise entry to Debug state. An External Debug Request debug event must be pending before writing 1 to this bit. Support for this feature is OPTIONAL and it is IMPLEMENTATION DEFINED when it is effective at forcing entry to Debug state.

The PE ignores writes to this bit if either:

- External debugging is not enabled, meaning `ExternalInvasiveDebugEnabled() == FALSE`.
- Secure external debugging is not enabled, meaning `ExternalSecureInvasiveDebugEnabled() == FALSE`, and either:
 - EL3 is not implemented and the implemented Security state is Secure state.
 - EL3 is implemented.

[Example H2-1](#) shows how entry to Debug state can be forced.

Example H2-1 Forcing entry to Debug state

The debugger pends an External Debug Request debug event through the CTI to halt a program that has stopped responding. However, the memory system is not responding and a memory access instruction cannot complete. This means that Debug state cannot be entered precisely. The debugger writes a value of 1 to [EDRCCR.CBRRQ](#). The PE cancels all outstanding memory accesses and enters Debug state. As some instructions might not have completed correctly, entry to Debug state is imprecise.

When Debug state is entered imprecisely, all memory access instructions executed through the ITR have UNPREDICTABLE behavior. The value of all registers is UNKNOWN, but might be useful for diagnostic purposes.

H2.2.7 Summary of actions from debug events

[Table H2-1](#) shows the Software and Halting debug events. In [Table H2-1](#) the columns have the following meaning:

Debug event type

This means the type of debug event where:

Other software

Means one of:

- [Software Step exceptions on page D2-1956](#).

- [Breakpoint Instruction exceptions](#) on page D2-1919.
- [Vector Catch exceptions](#) on page D2-1955 for AArch64 state or [Vector Catch exceptions](#) on page G2-4510 for AArch32 state.

Other Halting

Means one of the following:

- [Halting Step debug events](#) on page H3-5476.
- [External Debug Request debug event](#) on page H3-5490.
- [Reset Catch debug events](#) on page H3-5492.
- [OS Unlock Catch debug event](#) on page H3-5491.

Other debug events are referred to explicitly.

Authentication

This means halting is allowed by the IMPLEMENTATION DEFINED external authentication interface. It is the result of one of the following pseudocode functions:

In Secure state ExternalSecureInvasiveDebugEnabled().

In Non-secure state ExternalInvasiveDebugEnabled().

DLK This indicates whether the OS Double Lock is locked, DoubleLockStatus() == TRUE.

OSLK This is the value of OSLSR.OSLK. It indicates whether the OS Lock is locked.

HDE This is the value of EDSCR.HDE. It indicates whether Halting debug is enabled.

The letter X in [Table H2-1](#) indicates that the value can be either 0 or 1.

Table H2-1 Debug authentication for external debug

Debug event type	Authentication	DLK	OSLK	HDE	Behavior
Other software	X	X	X	X	Handled by the Exception model
Breakpoint or Watchpoint debug event	X	TRUE	X	X	Handled by the Exception model (ignored)
	X	FALSE	1	X	Handled by the Exception model (ignored)
	FALSE	FALSE	0	X	Handled by the Exception model
	TRUE	FALSE	0	0	Handled by the Exception model
	TRUE	FALSE	0	1	Entry to Debug state
Halt Instruction debug event	FALSE	X	X	X	UNDEFINED
	TRUE	TRUE	X	X	UNDEFINED
	TRUE	FALSE	X	0	UNDEFINED
	TRUE	FALSE	X	1	Entry to Debug state
Exception Catch debug event	FALSE	X	X	X	Ignored
	TRUE	TRUE	X	X	Ignored
	TRUE	FALSE	X	X	Entry to Debug state
Software Access debug event	FALSE	X	X	X	Ignored
	TRUE	TRUE	X	X	Ignored
	TRUE	FALSE	1	X	Ignored
	TRUE	FALSE	0	X	Entry to Debug state

Table H2-1 Debug authentication for external debug (continued)

Debug event type	Authentication	DLK	OSLK	HDE	Behavior
Other Halting	FALSE	X	X	X	Debug event is pended
	TRUE	TRUE	X	X	Debug event is pended
	TRUE	FALSE	X	X	Entry to Debug state

H2.2.8 Pseudocode description of Halting on debug events

The `Halted()`, `Restarting()`, `HaltingAllowed()`, and `HaltOnBreakpointOrWatchpoint()` functions are described in the ARMv8 pseudocode.

H2.3 Entering Debug state

On entry to Debug state, the preferred restart address and **PSTATE** are saved in **DLR** and **DSPSR**. The PE remains in the mode and security state from which it entered Debug state.

If **EDRCR.CBRRQ** has a value of 0, entry to Debug state is precise. If **EDRCR.CBRRQ** has a value of 1, then imprecise entry to Debug state is permitted.

If a Watchpoint debug event causes an entry to Debug state, the address of the access that generated the Watchpoint debug event is recorded in **EDWAR**.

See:

- [Determining the memory location that caused a Watchpoint exception on page D2-1948](#) for a debug event taken from AArch64 state.
- [Determining the memory location that caused a Watchpoint exception on page G2-4504](#) for a debug event taken from AArch32 state.

Other than the effect on **PSTATE** and **EDSCR**, entry to Debug state is not a *Context synchronization event*. The effects of entry to Debug state on **PSTATE** and **EDSCR** are synchronized.

H2.3.1 Entering Debug state from AArch32 state

When entering Debug state from AArch32 state, the PE remains in AArch32 state. In AArch32 Debug state the PE executes T32 instructions, regardless of the value of **PSTATE.T** before entering Debug state.

To allow the debugger to determine the state of the PE, the current Execution state for all four Exception levels can be read from **EDSCR.RW**, and the current Exception level can be read from **EDSCR.EL**.

The current endianness state, **PSTATE.E**, is unchanged on entry to Debug state.

———— **Note** —————

- If EL1 is using AArch32 state, the current endianness state can differ from that indicated by **SCTLR.EE**.
- If EL2 is using AArch32 state, the current endianness state can differ from that indicated by **HSCTLR.EE**.
- On entry to Debug state from AArch32 state, **PSTATE.SS** is copied to **DSPSR.SS**, even though the PE remains in AArch32 state.

See also [Effect of entering Debug state on PSTATE on page H2-5443](#).

H2.3.2 Effect of Debug state entry on DLR and DSPSR

DLR is set to the preferred restart address for the debug event, that depends on the event type. The value of **PSTATE** is saved in **DSPSR**. For entry to Debug state from AArch32 state, the values saved in **DSPSR.IT** are always correct for the preferred restart address.

For synchronous Halting debug events, the preferred restart address is the address of the instruction that generated the debug event.

For asynchronous Halting debug events, including pending Halting debug events taken asynchronously, the preferred restart address is the address of the first instruction that must be executed on exit from Debug state.

This means that:

- For Breakpoint and Watchpoint debug events, the preferred restart address is the same as the preferred return address for a debug exception, as described in [Chapter D2 AArch64 Self-hosted Debug](#) and [Chapter G2 AArch32 Self-hosted Debug](#).
- For Halt Instruction debug events **DLR** is set to the address of the HLT instruction and **DSPSR.IT** is correct for the HLT instruction.

- For Software Access debug events, **DLR** is set to the address of the accessing instruction and **DSPSR.IT** is correct for this instruction.
 - For Halting Step debug events taken synchronously, **DLR** and **DSPSR** are set as the ELR and SPSR would be set for a Software Step exception. This is usually the address of, and **PSTATE** for, the instruction after the one that was stepped.
 - For Exception Catch debug events:
 - If the debug event is generated on taking an exception to a trapped Exception level, the **DLR** is set to the address of the exception vector the PE would have started fetching from. This is UNKNOWN if the **VBAR** for the Exception level has never been initialized. The **DSPSR** records the value of **PSTATE** after taking the exception. The Exception Catch occurs after the **SPSR** and the Link register are set, and the debugger can use these registers to determine where in the application program the exception occurred.
- **Note** —————
- Depending on the target Exception level and Execution state for the exception, the Link register is one of **ELR_EL1**, **ELR_EL2**, **ELR_EL3**, **ELR_hyp**, or LR (R14).
- If the debug event is generated on an exception return to a trapped Exception level, the **DLR** is set to the target address of the exception return and the **DSPSR** records the value of **PSTATE** after the exception return.
- Reset Catch debug events taken synchronously behave like Exception Catch debug events.
 - For Reset Catch debug events and Exception Catch debug events generated on reset to a trapped Exception level, the **DLR** is set to is set to the reset address and the **DSPSR** records the reset value of **PSTATE**.
 - For pending Halting debug events and External Debug Request debug events, **DLR** is set to the address of the first instruction that must be executed on exit from Debug state and **DSPSR.IT** is correct for this instruction. See *Pending Halting debug events on page H3-5494*.

Normally **DLR** is aligned according to the instruction set state indicated in **DSPSR**. However, a debug event might be taken at a point where the PC is not aligned.

H2.3.3 Effect of Debug state entry on System registers, the Event register, and Exclusives monitors

Entering Debug state has no effect on System registers other than **DLR** and **DSPSR**. In particular, ESRs, FARs, and FSRs are not updated on entering Debug state. **SCR** is unchanged, even when entering Debug state from EL3.

Entering Debug state has no architecturally-defined effect on the Event Register and Exclusives monitors.

———— **Note** —————

Entry to Debug state might set the Event Register or clear the Exclusives monitors, or both. However, this is not a requirement, and debuggers must not rely on any implementation specific behavior.

Unless otherwise described in this reference manual, instructions executed in Debug state have their architecturally-defined effects on the System registers, the Event register, and Exclusives monitors.

H2.3.4 Effect of entering Debug state on PSTATE

The effect of an entry to Debug state on **PSTATE** is described in *Entering Debug state on page H2-5442* and *Entering Debug state from AArch32 state on page H2-5442*.

PSTATE.{E, M, nRW, EL, SP} are unchanged on entry to Debug state.

PSTATE.IL is cleared to 0 on entry to Debug state, after being saved in **DSPSR_EL0**.

PSTATE.PAN is saved in **DSPSR_EL0.PAN**.

PSTATE.UAO is saved in **DSPSR_EL0.UAO**.

The other `PSTATE` fields are ignored and not observable in Debug state:

- `PSTATE`.{N, Z, C, V, Q, GE} are unchanged.
- `PSTATE`.{IT, T, SS, D, A, I, F} are set to UNKNOWN values, after being saved in `DSPSR_EL0`.

For more information see *Process state (PSTATE) in Debug state* on page H2-5445.

H2.3.5 Entering Debug state during loads and stores

The PE can enter Debug state during instructions that perform a sequence of memory accesses, as opposed to a single single-copy atomic access, because of a Watchpoint debug event. The effect of entering Debug state on such an instruction is the same as taking a Data Abort exception during such an instruction.

In addition, when executing in AArch64 state, the PE can enter Debug state during instructions that perform a sequence of memory accesses because of an External Debug Request debug event. The effect of entering Debug state on such an instruction is the same as taking an interrupt exception during such an instruction.

This applies to all memory types.

H2.3.6 Entering Debug state and Software Step

When Software Step is active, a debug event that causes entry to Debug state behaves like an exception taken to an Exception level above the debug target Exception level. That is:

- If the instruction that is stepped generates a synchronous debug event that causes entry to Debug state, or an asynchronous debug event is taken before the step completes, the PE enters Debug state with `DSPSR.SS` set to 1.
- A pending Halting debug event or an asynchronous debug event can be taken after the step has completed. In this case the PE enters Debug state with `DSPSR.SS` set to 0.

In addition:

- If the instruction that is stepped generates an exception trapped by an Exception Catch debug event, the PE enters Debug state at the exception vector with `DSPSR.SS` set to 0. This is because `PSTATE.SS` is set to 0 by taking the exception.
- If the PE is reset, `PSTATE.SS` is reset to 0. If the following debug events are enabled, the PE enters Debug state with `DSPSR.SS` set to 0:
 - Reset Catch debug event at the reset Exception level.
 - Exception Catch debug event at the reset Exception level.
 - Halting Step debug event.
- If Halting Step is also active, then Halting Step and Software Step operate in parallel and can both become active-pending. In this case Halting step has a higher priority than Software step. This means that the PE enters Debug state and `DSPSR.SS` is set to 0.

H2.3.7 Pseudocode description of entering Debug state

The `DebugHalt` constants are described in *shared/debug/halting/DebugHalt* on page J1-6015 in the ARMv8 pseudocode. The `UpdateEDSFields()` and `Halt()` functions are described in *Chapter J1 ARMv8 Pseudocode*.

H2.4 Behavior in Debug state

Instructions are executed in Debug state from the Instruction Transfer Register, ITR. The debugger controls which instructions are executed in Debug state by writing the instructions to the External Debug Instruction Transfer register, [EDITR](#). The Execution state of the PE determines which instruction set is executed:

- If the PE is in AArch64 state it executes A64 instructions.
- If the PE is in AArch32 state it executes T32 instructions:
 - For a 32-bit T32 instruction, [EDITR\[15:0\]](#) specifies the first halfword and [EDITR\[31:16\]](#) specifies the second halfword.
 - For a 16-bit T32 instruction, [EDITR\[15:0\]](#) contains the instruction and [EDITR\[31:16\]](#) is ignored. All 16-bit T32 instructions are UNPREDICTABLE in debug state.

The PE does not execute A32 instructions in Debug state.

Some instructions are available only in Debug state. See *Debug state operations, DCPS, DRPS, MRS, MSR* on page H2-5461. In Non-debug state these instructions are UNDEFINED.

The following sections describe behavior in Debug state:

- *Process state (PSTATE) in Debug state.*
- *Executing instructions in Debug state* on page H2-5446.
- *Decode tables* on page H2-5457.
- *Security in Debug state* on page H2-5460.
- *Privilege in Debug state* on page H2-5461.
- *Debug state operations, DCPS, DRPS, MRS, MSR* on page H2-5461.
- *Exceptions in Debug state* on page H2-5465.
- *Accessing registers in Debug state* on page H2-5467.
- *Accessing memory in Debug state* on page H2-5470.

This section specifies the CONSTRAINED UNPREDICTABLE behaviors that apply in Debug state, but see *Changing the value of EDECR.SS when not in Debug state* on page H3-5483 for a change in Non-debug state that causes CONSTRAINED UNPREDICTABLE behavior.

H2.4.1 Process state (PSTATE) in Debug state

[PSTATE](#).{N, Z, C, V, Q, GE, IT, T, SS, D, A, I, F} are all ignored in Debug state:

- There are no conditional instructions in Debug state.
- In AArch32 state, the PE only executes T32 instructions and [PSTATE.IT](#) is ignored.
- Asynchronous exceptions and debug events are ignored.
- Software step is inactive.

Instructions executed in Debug state indirectly read [PSTATE](#).{IL, E, M, nRW, EL, SP} as they would in Non-debug state.

On entry to Debug state from AArch64:

- [PSTATE.PAN](#) is copied to [DSPSR_EL0.PAN](#).
- [PSTATE.UAO](#) is copied to [DSPSR_EL0.UAO](#).

On exit from Debug state to AArch64:

- [DSPSR_EL0.PAN](#) is copied to [PSTATE.PAN](#).
- [DSPSR_EL0.UAO](#) is copied to [PSTATE.UAO](#).

On entry to Debug state from AArch32, [CPSR.PAN](#) is copied to [DSPSR.PAN](#).

On exit from Debug state to AArch32, [DSPSR.PAN](#) is copied to [CPSR.PAN](#).

In Debug state:

- **PSTATE.PAN** is set to 1 by:
 - A DCPS instruction to EL1 using AArch64 if **SCTLR_EL1.SPAN** == 0.
 - A DCPS instruction to EL2 using AArch64 if **SCTLR_EL2.SPAN** == 0.
- **SPSR_ELx.PAN** is copied to:
 - **PSTATE.PAN** by the DRPS instruction to AArch64 from AArch64.
 - **CPSR.PAN** by the DRPS instruction to AArch32 from AArch64.

———— **Note** —————

A debugger can use a DRPS instruction to modify the PAN state bit.

- **PSTATE.UAO** is set to 0 by a DCPS instruction to AArch64.
- **SPSR_ELx.UAO** is copied to **PSTATE.UAO** by the DRPS instruction to AArch64 from AArch64.
- **PSTATE.UAO** operates as in Non-debug state.

H2.4.2 Executing instructions in Debug state

The instructions executed in Debug state must be either A64 instructions or T32 instructions, depending on the current Execution state.

Each instruction falls into one of the following groups:

- Debug state instructions. These are instructions that are changed in Debug state. See *A64 instructions that are changed in Debug state* and *T32 instructions that are changed in Debug state* on page H2-5452.
- Instructions that are unchanged in Debug state. See *A64 instructions that are unchanged in Debug state* on page H2-5447 and *T32 instructions that are unchanged in Debug state* on page H2-5452.
- Instructions that are UNPREDICTABLE or CONSTRAINED UNPREDICTABLE in Debug state. See *A64 instructions that are CONSTRAINED UNPREDICTABLE in Debug state* on page H2-5449 and *T32 instructions that are CONSTRAINED UNPREDICTABLE in Debug state* on page H2-5454.

All T32 instructions are treated as unconditional, regardless of **PSTATE.IT**. See *Process state (PSTATE) in Debug state* on page H2-5445.

If **EDSCR.SDD** == 1 then an instruction executed in Non-secure state cannot cause entry into Secure state. See *Security in Debug state* on page H2-5460

Executing A64 instructions in Debug state

The following sections describe the behavior of the A64 instructions in Debug state:

- *A64 instructions that are changed in Debug state.*
- *A64 instructions that are unchanged in Debug state* on page H2-5447.
- *A64 instructions that are CONSTRAINED UNPREDICTABLE in Debug state* on page H2-5449.

A64 instructions that are changed in Debug state

The following A64 instructions are defined in Debug state, but are UNDEFINED in Non-debug state:

- DCPS.

———— **Note** —————

DCPS can be UNDEFINED in certain conditions in Debug state. See *DCPS<n>* on page H2-5461.

- DRPS.
- MRS (**DLR_EL0**), MRS (**DSPSR_EL0**), MSR (**DLR_EL0**), MSR (**DSPSR_EL0**)

For more information see [Debug state operations, DCPS, DRPS, MRS, MSR](#) on page H2-5461.

A64 instructions that are unchanged in Debug state

The following list shows the instructions that are unchanged in Debug state:

Any instruction that is UNDEFINED in Non-debug state

This list of instructions excludes:

- Any instruction listed in [A64 instructions that are changed in Debug state](#) on page H2-5446.
- Any instruction listed in [A64 instructions that are CONSTRAINED UNPREDICTABLE in Debug state](#) on page H2-5449 that is UNDEFINED because an enable or disable bit is not RES0 or RES1

Instructions that move System or Special-purpose registers to or from a general-purpose register

This list of instructions:

- Includes the instructions to transfer a general-purpose register to or from the DTR, which can be executed at any Exception level.
- Excludes PSTATE access instructions.

These instructions are:

- MRS <special_reg>, MSR <special_reg>.

———— **Note** ————

This does not include NZCV, DAIF, DAIFSet, DAIFClr, SPSel, and CurrentEL.

- MRS <system_reg>, MSR <system_reg>.

Floating-point moves between a SIMD&FP register and a general-purpose register

These instructions are:

- **FMOV (between a general-purpose register and a half-precision register).**
- FMOV (between a general-purpose register and a single-precision register).
- FMOV (between a general-purpose register and a double-precision register).
- FMOV (between a general-purpose register and a SIMD element).

SIMD moves between a SIMD&FP register and a general-purpose register

These instructions are:

- INS (from a general-purpose register to a SIMD element).
- UMOV (from a SIMD element to a general-purpose register).

Barriers

These instructions are:

- ISB.
- DSB.
- DMB.

Memory access instructions at various access sizes

The following constraints apply:

- General purpose-registers only.
- One of the following addressing modes:
 - Unscaled (9-bit signed) immediate offset.
 - Immediate (9-bit signed) post-indexed.
 - Immediate (9-bit signed) pre-indexed.
 - Unprivileged (9-bit signed).
- Not literal.

- One of the following types:
 - (Single) register.
 - Exclusive.
 - Exclusive pair.
 - Acquire/Release.
 - Acquire/Release Exclusive.
 - Acquire/Release Exclusive pair.
- 32-bit and 64-bit target register variants.

These instructions are:

- LDR, LDRB, LDRH, LDRSB, LDRSH, LDRSW (immediate, not literal).
- LDUR, LDURB, LDURH, LDURSB, LDURSH, LDURSW (immediate).
- LDTR, LDTRB, LDTRH, LDTRSB, LDTRSH, LDTRSW (immediate).
- LDAR, LDARB, LDARH, LDXR, LDXRB, LDXRH, LDAXR, LDAXRB, LDAXRH.
- LDXP, LDAXP.
- STR, STRB, STRH (immediate).
- STUR, STURB, STURH (immediate).
- STTR, STTRB, STTRH (immediate).
- STLR, STLRB, STLRH, STXR, STXRB, STXRH, STLXR, STLXRB, STLXRH.
- STXP, STLXP.
- LDLAR, LDLARB, LDLARH - ARMv8.1 instructions.
- STLLR, STLLRB, STLLRH - ARMv8.1 instructions.
- CAS, CASB, CASH, CASP - ARMv8.1 instructions.
- SWP, SWPB, SWPH - ARMv8.1 instructions.
- LDADD, LDADDB, LDADDH - ARMv8.1 instructions.
- LDCLR, LDCLB, LDCLR - ARMv8.1 instructions.
- LDEOR, LDEORB, LDEORH - ARMv8.1 instructions.
- LDSET, LDSETB, LDSETH - ARMv8.1 instructions.
- LDSMAX, LDSMAXB, LDSMAXH - ARMv8.1 instructions.
- LDSMIN, LDSMINB, LDSMINH - ARMv8.1 instructions.
- LDUMAX, LDUMAXB, LDUMAXH - ARMv8.1 instructions.
- LDUMIN, LDUMINB, LDUMINH - ARMv8.1 instructions.
- STADD, STADDB, STADDH - ARMv8.1 instructions.
- STCLR, STCLB, STCLR - ARMv8.1 instructions.
- STEOR, STEORB, STEORH - ARMv8.1 instructions.
- STSET, STSETB, STSETH - ARMv8.1 instructions.
- STSMAX, STSMAXB, STSMAXH - ARMv8.1 instructions.
- STSMIN, STSMINB, STSMINH - ARMv8.1 instructions.
- STUMAX, STUMAXB, STUMAXH - ARMv8.1 instructions.
- STUMIN, STUMINB, STUMINH - ARMv8.1 instructions.

Move immediate to general-purpose register

These instructions are:

- MOVZ, MOVN, MOVK (immediate).
- MOV (between a general-purpose register and the stack pointer).

System instructions, Send Event, NOP, and Clear Exclusive

In this context, the System instructions are the Cache maintenance instructions, TLB maintenance instructions, and the Address translation instructions.

These instructions are:

- IC.
- DC.
- TLBI.
- AT.
- SEV, SEVL.
- NOP.
- CLREX.

A64 instructions that are **CONSTRAINED UNPREDICTABLE** in Debug state

This subsection describes all instruction not listed in either:

- [A64 instructions that are changed in Debug state on page H2-5446](#).
- [A64 instructions that are unchanged in Debug state on page H2-5447](#).

These instructions are **CONSTRAINED UNPREDICTABLE** in Debug state. In general, the permissible behaviors are:

- The instruction is **UNDEFINED**.
- The instruction executes as a **NOP**.
- If the instruction reads the PC or PSTATE, it uses an **UNKNOWN** value.
- If the instruction modifies the PC or PSTATE, other than by advancing the PC to the sequentially next instruction, it sets **DLR_EL0** and **DSPSR_EL0** to **UNKNOWN** values.
- If the instruction is similar to a Debug state instruction, it executes as that Debug state instruction.
- The instruction has the same behavior as in Non-debug state.

The following list shows the permissible behaviors for A64 instruction in Debug state. An instruction might appear multiple times in the list, in which case the choice of permissible behaviors is any of those listed. An example of this is **CCMP**.

Exception-generating instructions

These instructions are:

- SVC.
- HVC.
- SMC.
- BRK.
- HLT.

These instructions behave in one of the following ways:

- They are **UNDEFINED**.
- They execute as a **NOP**.
- SVC behaves as **DCPS1**.
- HVC behaves as **DCPS2**.
- SMC behaves as **DCPS3**.
- They generate the exception that the instruction would generate in Non-debug state. The exception is taken as described in [Exceptions in Debug state on page H2-5465](#)

————— **Note** —————

SMC must not generate a Secure Monitor Call exception from Non-secure state if **EDSCR.SDD** is set to 1.

Instructions that explicitly write to the PC (branches)

These instructions are:

- B, B.cond, BL, BLR, BR, CBZ, CBNZ, RET, TBZ, TBNZ.

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a NOP.
- They execute as in Non-debug state without branching and set [DSPSR_ELO](#) and [DLR_ELO](#) to UNKNOWN values.

Exception return and related instructions

These instructions are:

- ERET.

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a NOP.
- They execute as in Non-debug state without branching. They set [DSPSR_ELO](#) and [DLR_ELO](#) to UNKNOWN values, and either:
 - Execute the DRPS operation instead of performing an exception return, using UNKNOWN SPSR values.
 - Not change the Exception level.

Instructions that explicitly modify PSTATE, other than DCPS and DRPS

These instructions are:

- MSR DAIFSet (immediate), MSR DAIFClr (immediate), MSR SPSe1 (immediate).
- MSR NZCV (register), MSR DAIF (register), MSR SPSe1 (register).
- MSR PAN (immediate) - ARMv8.1 instruction.
- **MSR UAO (immediate) - ARMv8.2 instruction.**

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a NOP.
- They execute as in Non-debug state, setting [DSPSR_ELO](#) and [DLR_ELO](#) to UNKNOWN values.

Instructions that request entry to a low-power state

These instructions are:

- WFE, WFI.

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a NOP.
- They generate a synchronous exception if the corresponding instruction would be trapped in Non-debug state. See [Configurable instruction enables and disables, and trap controls on page D1-1842](#).
- A WFE instruction clears the Event register if it is set.

————— **Note** —————

This means that these instructions must not suspend execution.

Instructions that read the PC

These instructions are:

- LDR (literal), LDRSW (literal).
- ADR, ADRP.
- PRFM (literal).

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a NOP.
- They execute as in Non-debug state, using an UNKNOWN value for the PC operand.

Instructions that read the PSTATE.{N, Z, C, V} or other PSTATE fields

These instructions are:

- CSEL, CSINC, CSINV, CSNEG, CCMN, CCMP, FCSEL, FCCMP, FCCMPE.
- ADC, ADCS, SBC, SBCS.
- MRS NZCV, MRS DAIF, MRS SPSEL, MRS CurrentEL.

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a NOP.
- They execute as in Non-debug state:
 - For the conditional operations and those using the PSTATE.C flag as an input, these instructions use an UNKNOWN value for the Condition flag.
 - For the MRS instruction, they return an UNKNOWN value.

Instructions that explicitly modify the PSTATE. {N, Z, C, V, Q, GE}

These instructions are:

- ADDS, SUBS, ADCS, SBCS, ANDS, BICS, CCMN, CCMP.
- FCMP, FCMPE, FCCMP, FCCMPE.
- MSR NZCV (register).

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a NOP.
- They execute as in Non-debug state, setting [DPSR_ELO](#) and [DLR_ELO](#) to UNKNOWN values.

All other instructions

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a NOP.
- They have the same behavior as in Non-debug state.

————— Note —————

This includes instructions defined as UNPREDICTABLE or CONSTRAINED UNPREDICTABLE in Non-debug state. These instructions are UNPREDICTABLE or CONSTRAINED UNPREDICTABLE in Debug state.

Executing T32 instructions in Debug state

The following sections describe the behavior of the T32 instructions in Debug state:

- [T32 instructions that are changed in Debug state.](#)
- [T32 instructions that are unchanged in Debug state.](#)
- [T32 instructions that are CONstrained UNPREDICTABLE in Debug state on page H2-5454.](#)

T32 instructions that are changed in Debug state

The following T32 instructions are defined in Debug state, but are UNDEFINED in Non-debug state:

- DCPS

———— **Note** —————

DCPS can be UNDEFINED in certain conditions in Debug state. See [DCPS<n> on page H2-5461.](#)

- MRC p15, 3, <Rt>, c4, c5, 0 (DSPSR).
- MCR p15, 3, <Rt>, c4, c5, 0 (DSPSR).
- MRC p15, 3, <Rt>, c4, c5, 1 (DLR).
- MCR p15, 3, <Rt>, c4, c5, 1 (DLR).

In addition, ERET executes the DRPS operation in Debug state.

For more information see [Debug state operations, DCPS, DRPS, MRS, MSR on page H2-5461.](#)

T32 instructions that are unchanged in Debug state

The following list shows the instructions that are unchanged in Debug state. Any T32 instruction that uses the PC or APSR. {N, Z, C, V} as the source or destination register is not included in the list. Moreover, the list only includes the 32-bit T32 encodings.

Any instruction that is UNDEFINED in Non-debug state

The list of instructions:

- Excludes any instruction listed in [T32 instructions that are changed in Debug state.](#)
- Excludes any instruction listed in [T32 instructions that are CONstrained UNPREDICTABLE in Debug state on page H2-5454](#) that is UNDEFINED because an enable or disable bit is not RES0 or RES1

Instructions that move System or Special-purpose registers to or from a general-purpose register

The list of instructions:

- Includes the instructions to transfer a general-purpose register to or from the DTR, which can be executed at any Exception level.
- Excludes APSR and CPSR access instructions.
- Excludes instructions for accessing banked registers for the current mode.

These instructions are:

- MRS <banked_reg>, MSR <banked_reg>.

———— **Note** —————

This does not apply to cases which are UNPREDICTABLE or CONstrained UNPREDICTABLE in Non-debug state in the current mode.

- MRC, MCR.

———— **Note** —————

This includes all allocated System registers in the (coproc==0b111x) encoding space other than an MRC move to APSR_nzcv.

- MRS SPSR, MSR SPSR.

- VMRS <vfp_system_reg>, VMSR <vfp_system_reg>.

———— **Note** ————

This includes all allocated Advanced SIMD and floating-point System registers, other than an a VMRS move to APSR_nzcv.

Floating-point moves between a SIMD&FP register and a general-purpose register

These instructions are:

- VMOV (between a general-purpose register and a single-precision register).
- VMOV (between a general-purpose register and a doubleword floating-point register).

SIMD moves between a SIMD&FP register and a general-purpose register

These instructions are:

- VMOV (between a general-purpose register and a scalar).

Barriers

These instructions are:

- ISB.
- DSB.
- DMB.

Memory access instructions at various access sizes

The following constraints apply:

- General purpose-registers only.
- One of the following addressing modes:
 - Immediate (8-bit or 12-bit) offset.
 - Immediate (8-bit) post-indexed.
 - Immediate (8-bit) pre-indexed.
 - Unprivileged (8-bit).
- Not literal.
- One of the following types:
 - (Single) register.
 - Dual.
 - Exclusive.
 - Exclusive doubleword.
 - Acquire/Release.
 - Acquire/Release Exclusive.
 - Acquire/Release Exclusive doubleword.

These instructions are:

- LDR.W, LDRB.W, LDRH.W, LDRD, LDRSB.W, LDRSH.W (immediate, not literal).
- LDRT, LDRBT, LDRHT, LDRSBT, LDRSHT (immediate).
- LDREX, LDREXB, LDREXH, LDA, LDAB, LDAH, LDAEX, LDAEXB, LDAEXH.
- LDREXD, LDAEXD.
- STR.W, STRB.W, STRH.W, STRD (immediate).
- STRT, STRBT, STRHT (immediate).
- STREX, STREXB, STREXH, STL, STLB, STLH, STLEX, STLEXB, STLEXH.
- STREXD, STLEXD.

Move to general-purpose register

These instructions are:

- MOVW, MOVT (immediate).

System instructions, Send Event, NOP, and Clear Exclusive

The System instructions are Cache maintenance instructions, TLB maintenance instructions, and Address translation instructions. These are encoded in the (coproc==0b1111) System register encoding space.

These instructions are:

- [ICIALLU, ICIALLUIS, ICIMVAU.](#)
- [DCCIMVAC, DCCISW, DCCMVAC, DCCMVAU, DCCSW, DCIMVAC, DCISW.](#)
- [TLBIALL, TLBIALLH, TLBIALLHIS, TLBIALLIS, TLBIALLNSNH, TLBIALLNSNHIS, TLBIASID, TLBIASIDIS, TLBIIPAS2, TLBIIPAS2IS, TLBIIPAS2L, TLBIIPAS2LIS, TLBIMVA, TLBIMVAA, TLBIMVAAIS, TLBIMVAAL, TLBIMVAALIS, TLBIMVAH, TLBIMVAHIS, TLBIMVAIS, TLBIMVAL, TLBIMVALH, TLBIMVALHIS, TLBIMVALIS.](#)
- [ATS12NSOPR, ATS12NSOPW, ATS12NSOUR, ATS12NSOUW, ATS1CPR, ATS1CPW, ATS1CUR, ATS1CUW, ATS1HR, ATS1HW.](#)
- [BPIALL, BPIALLIS, BPIMVA.](#)
- [SEV.W, SEVL.W.](#)
- [NOP.W.](#)
- [CLREX.](#)

T32 instructions that are **CONSTRAINED UNPREDICTABLE** in Debug state

This subsection describes all instruction not listed in either:

- [T32 instructions that are changed in Debug state on page H2-5452.](#)
- [T32 instructions that are unchanged in Debug state on page H2-5452.](#)

These instructions are **CONSTRAINED UNPREDICTABLE** in Debug state. In general, the permissible behaviors are:

- The instruction generates an Undefined Instruction exception.
- The instruction executes as a NOP.
- If the instruction reads the PC or PSTATE, it uses an UNKNOWN value.
- If the instruction modifies the PC or PSTATE, other than by advancing the PC to the sequentially next instruction, it sets [DLR](#) and [DSPSR](#) to UNKNOWN values.
- If the instruction is similar to a Debug state instruction, it executes as that Debug state instruction.
- The instruction has the same behavior as in Non-debug state.

The following list shows the permissible behaviors for T32 instruction in Debug state. An instruction might appear multiple times in the list, in which case the choice of permissible behaviors is any of those listed.

Exception-generating instructions

These instructions are:

- [SVC.](#)
- [HVC.](#)
- [SMC.](#)
- [UDF.](#)
- [BKPT.](#)
- [HLT.](#)

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a NOP.
- SVC behaves as DCPS1.

- HVC behaves as DCPS2.
- SMC behaves as DCPS3.
- They generate the exception the instruction would generate in Non-debug state. The exception is taken as described in *Exceptions in Debug state* on page H2-5465

———— **Note** ————

SMC must not generate a Secure Monitor Call exception from Non-secure state if EDSCR.SDD is set to 1.

Instructions that explicitly write to the PC (branches)

These instructions are:

- B, B (conditional), CBZ, CBNZ BL.
- BX, BLX (register or immediate).
- BXJ, TBB, TBH.
- MOV pc and related instructions.
- LDR pc, LDM (with a register list includes the PC), POP (with a register list that includes the PC).

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a NOP.
- They execute as in Non-debug state without branching and set **DSPSR** and **DLR** to UNKNOWN values.

Exception return and related instructions, other than ERET

These instructions are:

- SRS, RFE, SUBS pc, 1r, and related instructions.

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a NOP.
- They execute as in Non-debug state without branching, setting **DSPSR_EL0** and **DLR_EL0** to UNKNOWN values, and either:
 - Execute the DPRS operation instead of performing an exception return, using UNKNOWN SPSR values.
 - Not changing Exception level or PE mode.

Instructions that explicitly modify PSTATE, other than DCPS and ERET

These instructions are:

- CPS, SETEND, IT.
- MSR APSR, CPSR (register or immediate).
- SETPAN.

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a NOP.
- They execute as in Non-debug state, setting **DSPSR_EL0** and **DLR_EL0** to UNKNOWN values.

Instructions that request entry to a low-power state

These instructions are:

- WFE, WFI.

These instructions behave in one of the following ways:

- They are UNDEFINED.

- They execute as a NOP.
- They generate a synchronous exception if the corresponding instruction would be trapped in Non-debug state. See [Configurable instruction enables and disables, and trap controls on page G1-4418](#).
- A WFE instruction is permitted to clear the Event register if it is set.

———— **Note** ————

This means that these instructions must not suspend execution.

Instructions that read the PC

These instructions are:

- LDR (literal), LDRB (literal), LDRH (literal), LDRSB (literal), LDRSH (literal).
- ADR, ADRL, ADRH.
- PLD (literal), PLI (literal).

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a NOP.
- They execute as in Non-debug state using an UNKNOWN value for the PC operand.

Instructions that read PSTATE.{N, Z, C, V} or other PSTATE fields

These instructions are:

- SEL, VSEL.
- ADC, SBC, all instructions with an RRX shift.
- MRS CPSR.

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a NOP.
- They execute as in Non-debug state:
 - For the conditional operations and those using the PSTATE.C flag as an input, these instructions use an UNKNOWN value for the Condition flag.
 - For the MRS instruction, they return an UNKNOWN value

Instructions that explicitly modify PSTATE.{N, Z, C, V, Q, GE}

These instructions are:

- CMP, TST, TEQ, CMN.
- <opc>S.
- MRC p14, 0, APSR_nzcv, c0, c1, 0 (DBGDSCRint).
- MSR CPSR, MSR APSR, (register or immediate).
- VMRS APSR_nzcv, FPSCR.
- QADD, QDADD, QSUB, QDSUB.
- SMLABB, SMLABT, SMLATB, SMLATT, SMLAD, SMLAWB, SMLAWT, SMLSD, SMUAD.
- SSAT, SSAT16, USAT, USAT16.
- SADD, SADD8, SADD16, SASX, SSAX, SSUB, SSUB8, SSUB16.
- UADD, UADD8, UADD16, UASX, USAX, USAUB, USUN8, USUB16.

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a NOP.
- They execute as in Non-debug state, setting [DSPSR_ELO](#) and [DLR_ELO](#) to UNKNOWN values.

All other instructions

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a NOP.
- They have the same behavior as in Non-debug state.

Note

This includes instructions defined as UNPREDICTABLE or CONSTRAINED UNPREDICTABLE in Non-debug state. These instructions are CONSTRAINED UNPREDICTABLE in Debug state. This includes some T32 instructions that specify R15 as a destination or source register.

[Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#) describes the CONSTRAINED UNPREDICTABLE behavior for these instructions. In Debug state these CONSTRAINED UNPREDICTABLE choices are further restricted:

- Instructions that specify R15 as a destination register:
 - Are not permitted to branch, because the architecture does not define a branch operation in Debug state.
 - Might set [DLR](#) and [DSPSR](#) to UNKNOWN values.
 - Might have any of the other permitted behaviors.
 - Instructions that specify R15 as a source operand:
 - Cannot use PC + offset, because there is no architecturally-defined PC in Debug state.
 - Might have any of the other permitted behaviors, including using an UNKNOWN value.
-

H2.4.3 Decode tables

The syntax in the tables is defined as follows:

1	The bit has a fixed value of 1.
0	The bit has a fixed value of 0.
!=	The field has any value other than the value or values specified. The field might be an encoding field in the instruction whose value is supplied by the debugger.

Note

The instruction encodings in [Chapter C6 A64 Base Instruction Descriptions](#) and [Chapter F5 T32 and A32 Base Instruction Set Instruction Descriptions](#) might show these bits as (0) or (1). A debugger must set these bits to 0 or 1, as appropriate.

Any other value indicates an encoding field in the instruction whose value is supplied by the debugger. Some values might be reserved or UNDEFINED, in which case the instruction is UNDEFINED or CONSTRAINED UNPREDICTABLE in Debug state, as it is in Non-debug state.

For more information about the instruction encodings, see:

- [Chapter C6 A64 Base Instruction Descriptions](#).
- [Chapter F5 T32 and A32 Base Instruction Set Instruction Descriptions](#).

For information about the syntax used in [Table H2-2 on page H2-5458](#), [Table H2-3 on page H2-5458](#), [Table H2-4 on page H2-5459](#), and [Table H2-5 on page H2-5460](#), see:

- [Common syntax terms on page C1-137](#).
- [Assembler symbols on page F2-2846](#).

Table H2-2 shows the A64 instructions that are modified in Debug state. For details of how these are packed in EDITR, see *EDITR, External Debug Instruction Transfer Register* on page H9-5632.

H2.4.4 Security in Debug state

If EL3 is implemented or the implemented Security state is Secure state, security in Debug state is governed by the Secure debug disabled flag, [EDSCR.SDD](#).

On entry to Debug state

If entering in Secure state, [EDSCR.SDD](#) is set to 0. Otherwise [EDSCR.SDD](#) is set to the inverse of `ExternalSecureInvasiveDebugEnabled()`. That is:

- If `ExternalSecureInvasiveDebugEnabled() == TRUE`, [EDSCR.SDD](#) is set to 0.
- If `ExternalSecureInvasiveDebugEnabled() == FALSE`, [EDSCR.SDD](#) is set to 1.

Note

Normally, if `ExternalSecureInvasiveDebugEnabled() == FALSE` then halting is prohibited and it is not possible to enter Debug state from Secure state. However, because changes to the authentication signals require a *Context synchronization event* to guarantee their effect, there is a period during which the PE might halt even though the authentication signals prohibit halting.

In Debug state

The value of `EDSCR.SDD` does not change, even if `ExternalSecureInvasiveDebugEnabled()` changes.

———— **Note** —————

- `DBGAUTHSTATUS_EL1`. {SNID, SID, NSNID, NSID} are not frozen in Debug state.
- If `EDSCR.SDD` set to 1 in Debug state, then there is no means to enter Secure state from Non-secure state. In this case it is impossible for the PE to be in Secure state. This is a general principle of behavior in Debug state.

In Non-debug state

`EDSCR.SDD` returns the inverse of `ExternalSecureInvasiveDebugEnabled()`. If the authentication signals that control `ExternalSecureInvasiveDebugEnabled()` change, a *Context synchronization event* is required to guarantee their effect.

———— **Note** —————

- In Non-debug state, `EDSCR.SDD` is unaffected by the Security state of the PE.
- A *Context synchronization event* is also required to guarantee that changes in the authentication signals are visible in `DBGAUTHSTATUS_EL1`. {SNID, SID, NSNID, NSID}.

If EL3 is not implemented and the implemented Security state is Non-Secure state, `EDSCR.SDD` is RES1.

H2.4.5 Privilege in Debug state

The only additional privileges offered to Debug state are:

- The privilege to execute *Debug state operations*, `DCPS`, `DRPS`, `MRS`, `MSR`.
- The privilege to execute DTR access instructions regardless of the Exception level and traps.

The DTR access instructions can be executed at any Exception level, including EL0, regardless of any control register settings that might force these instructions to be UNDEFINED or trapped in Non-debug state. These instruction are:

- The MRS and MSR instructions that access `DBGDTR_EL0`, `DBGDTRTX_EL0`, and `DBGDTRRX_EL0` in AArch64 state.
- The MRC and MCR instructions that access `DBGDTRTXint` and `DBGDTRRXint` in AArch32 state.

All other instructions operate with the privilege determined by the current Exception level and security state. This applies to all Special-purpose and System registers accesses, memory accesses, and UNDEFINED instructions, and includes generating exceptions when the System registers trap or disable an instruction.

H2.4.6 Debug state operations, DCPS, DRPS, MRS, MSR

ARMv8 defines operations to change between Exception levels in Debug state. These operations can also change the mode at the current Exception level.

DCPS<n>

Executing a `DCPS<n>` instruction in Debug state moves the PE to a higher Exception level or to a specific mode at the current Exception level.

If the `DCPS<n>` instruction is executed in AArch32 state and the target Exception level is using AArch64:

- The current instruction set switches from T32 to A64.
- The effect on registers that are not visible or only partially visible in AArch32 state is the same as for system calls in Non-debug state. See *Execution state* on page D1-1779.

Otherwise, the instruction set state does not change.

If the target Exception level is the same as the current Exception level, then the PE does not change Exception level. However, the PE might change mode.

The effect on endianness is the same as for exceptions and exception returns in Non-debug state:

- In AArch64 state the current endianness is determined by the value of `SCTLR_ELx.EE` for the target Exception level.
- In AArch32 state the current endianness is determined by the value of `SCTLR.EE` or `HSCTLR.EE` for the target Exception level.

The DCPS<n> instructions are:

In AArch64 state

- `DCPS1`
- `DCPS2`
- `DCPS3`

In AArch32 state, in the T32 instruction set only

- `DCPS1 variant`
- `DCPS2 variant`
- `DCPS3 variant`

The DCPS instructions are UNDEFINED in Non-debug state.

Table H2-6 shows the target of the instruction. In Table H2-6 the entries have the following meaning:

EL1h/Svc	This means that the target is: <ul style="list-style-type: none"> • EL1h if EL1 is using AArch64. • EL1 and Supervisor mode if EL1 is using AArch32.
EL2h/Hyp	This means that the target is: <ul style="list-style-type: none"> • EL2h if EL2 is using AArch64. • EL2 and Hyp mode if EL2 is using AArch32.
EL3h/Monitor	This means that the target is: <ul style="list-style-type: none"> • EL3h if EL3 is using AArch64. • EL3 and Monitor mode if EL3 is using AArch32.
Svc	Secure Supervisor mode, in EL3 using AArch32.
Monitor	Secure Monitor mode, in EL3 using AArch32.

Table H2-6 Target for DCPS instructions in Debug state

Instruction	Target when DCPS instruction executed at stated Exception level:				
	EL0	EL1	EL2	EL3 (AArch64)	EL3 (AArch32)
<code>DCPS1</code>	EL1h/Svc	EL1h/Svc	EL2h/Hyp	EL3h	Svc, clears <code>SCR.NS</code> to 0
<code>DCPS2</code>	EL2h/Hyp	EL2h/Hyp	EL2h/Hyp	EL3h	UNDEFINED
<code>DCPS3</code>	EL3h/Monitor	EL3h/Monitor	EL3h/Monitor	EL3h	Monitor, clears <code>SCR.NS</code> to 0

In AArch32 Monitor mode, `DCPS1` and `DCPS3` clear `SCR.NS` to 0.

Note

In AArch64 state, at EL3, DCPS<n> does not change [SCR_EL3.NS](#).

However:

- [DCPS1](#) is UNDEFINED at EL0 in Non-secure state if either:
 - EL2 is implemented and using AArch64 and [HCR_EL2.TGE](#) == 1.
 - EL2 is implemented and using AArch32 and [HCR.TGE](#) == 1.
- [DCPS2](#) is UNDEFINED at all Exception levels if EL2 is not implemented.
- [DCPS2](#) is UNDEFINED at the following Exception levels if EL2 is implemented:
 - At EL0 and EL1 in Secure state.
 - At EL3 if EL3 is using AArch32.
- [DCPS3](#) is UNDEFINED at all Exception levels if either:
 - [EDSCR.SDD](#) == 1.
 - EL3 is not implemented.

Note

The references to [DCPS1](#), [DCPS2](#), and [DCPS3](#) in this section link to the descriptions of the instructions in the A64 instruction set. The DCPS<n> instructions are also defined in the T32 instruction set, see [DCPS1](#), [DCPS2](#), [DCPS3](#) on [page F5-3101](#). These instructions are not defined in the A32 instruction set, because A32 instructions cannot be executed in Debug state.

On executing a DCPS instruction:

- If the target Exception level is using AArch64:
 - [ELR_ELx](#) of the target Exception level becomes UNKNOWN.
 - [SPSR_ELx](#) of the target Exception level becomes UNKNOWN.
 - [ESR_ELx](#) of the target Exception level becomes UNKNOWN.
 - [DLR_EL0](#) and [DSPSR_EL0](#) become UNKNOWN.
- If the target Exception level is using AArch32 [DLR](#) and [DSPSR](#) become UNKNOWN and:
 - If the target Exception level is EL1 or EL3, the LR and SPSR of the target mode become UNKNOWN.
 - If the target Exception level is EL2, then [ELR_hyp](#), [SPSR_hyp](#), and [HSR](#) become UNKNOWN.

If the target Exception level is using AArch32, and the target Exception level is EL1 or EL3, the LR and SPSR of the target mode become UNKNOWN.

The [DCPSInstruction\(\)](#) function is described in [Chapter J1 ARMv8 Pseudocode](#).

DRPS

Executing the DRPS operation in Debug state moves the PE to a lower Exception level, or to another PE mode at the current Exception level, by copying the current SPSR to [PSTATE](#).

If [DRPS](#) is executed in AArch64 state and the target Exception level is using AArch32:

- The current instruction set switches from A64 to T32.
- The effect on registers that are not visible or only partially visible in AArch32 state is the same as for exception returns in Non-debug state. See [Execution state on page D1-1779](#).

Otherwise the instruction set state does not change.

If the target Exception level is the same as the current Exception level, then the PE does not change Exception level. However, the PE might change mode.

The effect on endianness is the same as for exceptions and exception returns in Non-debug state:

- If targeting an Exception level using AArch64, current endianness is set according to [SCTLR_ELx.EE](#), or [SCTLR_EL1.EOE](#) for the target Exception level.
- If targeting an Exception level using AArch32, current endianness is set by [SPSR.E](#) as appropriate.

The DRPS instructions are:

In AArch64 state

- [DRPS](#)

In AArch32 state, in the T32 instruction set only

- [ERET](#)

If the SPSR specifies an illegal exception return, then [PSTATE](#).{M, nRW, EL, SP} are unchanged and [PSTATE.IL](#) is set to 1. For further information on illegal exception returns, see [Illegal return events from AArch64 state on page D1-1816](#).

[PSTATE](#).{N, Z, C, V, Q, GE, IT, T, SS, D, A, I, F} are ignored in Debug state. This means that the effect of the DRPS operation on these fields is to set them to an UNKNOWN value that might be the value from the SPSR. For more information see [Process state \(PSTATE\) in Debug state on page H2-5445](#).

All other [PSTATE](#) fields are copied from SPSR.

[DRPS](#) is UNDEFINED at EL0 and in Non-debug state.

———— Note —————

Unlike an exception return, the DRPS operation has no architecturally-defined effect on the Event Register and Exclusives monitors. DRPS might set the Event Register or clear the Exclusives monitors, or both, but this is not a requirement and debuggers must not rely on any implementation specific behavior.

On executing a DRPS instruction:

- If the target Exception level is using AArch64:
 - [DLR_EL0](#) and [DSPSR_EL0](#) become UNKNOWN.
- If the target Exception level is using AArch32:
 - [DLR](#) and [DSPSR](#) become UNKNOWN.

The [DRPSInstruction\(\)](#) function is described in [Chapter J1 ARMv8 Pseudocode](#).

MRS and MSR

The other Debug state instructions are used to read or write [DLR_EL0](#) and [DSPSR_EL0](#).

These instructions are:

In AArch64 state

- [MRS](#)
- [MSR \(register\)](#)

In AArch32 state

- [MRC](#)
- [MCR](#)

```
MRS <Xt>, DLR_EL0      ; Copy DLR_EL0 to <Xt>
MRS <Xt>, DSPSR_EL0    ; Copy DSPSR_EL0 to <Xt>
MSR DLR_EL0, <Xt>      ; Copy <Xt> to DLR_EL0
MSR DSPSR_EL0, <Xt>    ; Copy <Xt> to DSPSR_EL0
```

These instructions can be executed at any Exception level when in Debug state, including EL0. They are UNDEFINED in Non-debug state.

H2.4.7 Exceptions in Debug state

The following sections describe how exceptions are handled in Debug state:

- [Generating exceptions when in Debug state.](#)
- [Taking exceptions when in Debug state.](#)
- [Reset in Debug state on page H2-5467.](#)

Generating exceptions when in Debug state

In Debug state:

- Instruction Abort exceptions cannot happen because instructions are not fetched from memory.
- Interrupts, including SError and virtual interrupts are ignored and remain pending:
 - The pending interrupt remains visible in [ISR](#).
- Debug exceptions and debug events are ignored.
- [SCR.EA](#) is treated as if it were set to 0, regardless of its actual state, other than for the purpose of reading the bit.
- Any attempt to execute an instruction bit pattern that is an allocated instruction at the current Exception level, but is listed in [Executing instructions in Debug state on page H2-5446](#) as UNDEFINED in Debug state, generates an exception, that is taken to the current Exception level, or to EL1 if executing at EL0.

———— **Note** —————

If the exception is taken to an Exception level that is using AArch32 then it is taken as an Undefined Instruction exception.

The priority and syndrome for these exceptions is the same as for executing an encoding that does not have an allocated instruction.

- Instructions executed at EL2, EL1 and EL0 that are configured by EL3 control registers to trap to EL3:
 - When the value of [EDSCR.SDD](#) is 0, generate the appropriate trap exception that is taken to EL3.
 - When the value of [EDSCR.SDD](#) is 1, are treated as UNDEFINED and generate an exception that is taken to the current Exception level, or to EL1 if the instruction is executed at EL0. If the exception is taken to an Exception level that is using AArch32 it is taken as an Undefined Instruction exception.
If the exception is taken to an Exception level using AArch64 or to AArch32 Hyp mode, then it is reported with an EC value of 0x00.

Otherwise configurable traps, enables, and disables for instructions are unaffected by Debug state, and executing an affected instruction generates the appropriate exception.

Otherwise, synchronous exceptions, including Data Aborts, are generated as they would be in Non-debug state and taken to the appropriate Exception level in Debug state.

———— **Note** —————

If [EDSCR.SDD](#) == 1 then an exception from Non-secure state is never taken to Secure state. See [Security in Debug state on page H2-5460](#).

Taking exceptions when in Debug state

When the PE is in Debug state, all exceptions are synchronous. When an exception is generated, it is taken to Debug state. This means that:

- The target Exception level is as defined for the exception in Non-debug state.

- If the target Exception level is using AArch32 then the target PE mode is as defined for the exception in Non-debug state.
- The exception syndrome is reported as defined for the exception in Non-debug state, except for the case described in [Data Aborts in Memory access mode on page H4-5504](#) for which the reporting requirements are relaxed.

The exception syndrome is reported using the syndrome register or registers for the target Exception level. In AArch64 state, these are [ESR_ELx](#), and [FAR_ELx](#). In AArch32 state, these are [DFSR](#), [DFAR](#), [HSR](#), [HDFAR](#), and [HPFAR](#). For example:

- If a Data Abort exception is taken to Abort mode at EL1 or EL3 and the exception is taken from AArch32 state and using the Short-descriptor translation table format, the [DFSR](#) reports the exception using the Short-descriptor format fault encoding. For exceptions other than Data Abort exceptions taken to Abort mode, [DFSR](#) is not updated.
- If an instruction is trapped to an Exception level using AArch64 due to a configurable trap, disable, or enable, the exception code reported is the same as it would be in Non-debug state.

The effect on auxiliary syndrome registers, such as AFSR, is IMPLEMENTATION DEFINED.

———— **Note** —————

Generally, the AArch32 Fault Address Registers (FARs) and Fault Status Registers (FSRs) are not described as *syndrome registers*, although the term is appropriate to their function.

- The PE remains in Debug state and changes to the target mode.
- If EL3 is using AArch32 and the exception is taken from Monitor mode, [SCR.NS](#) is cleared to 0.
- If the exception is taken to an Exception level using AArch32, the PE continues to execute T32 instructions, regardless of the TE bit in the System register for the target Exception level.
- The endianness switches to that indicated by the EE bit of the System register for the target Exception level.
- The SPSR for the target Exception level or mode is corrupted and becomes UNKNOWN.
- If the target Exception level is using AArch64, [ELR_ELx](#) for the target Exception level becomes UNKNOWN.
- If the target Exception level is EL2 using AArch32, [ELR_hyp](#) becomes UNKNOWN.
- If the target Exception level is EL1 or EL3 using AArch32, [LR_<mode>](#) for the target mode becomes UNKNOWN.
- [DLR](#) and [DSPSR](#) become UNKNOWN.
- The cumulative error flag, [EDSCR.ERR](#), is set to 1. See [Cumulative error flag on page H4-5508](#).
- [PSTATE.IL](#) is cleared to 0.
- [PSTATE](#).{IT, T, SS, D, A, I, F} are set to UNKNOWN values, and [PSTATE](#).{N, Z, C, V, Q, GE} are unchanged. However, these fields are ignored and are not observable in Debug state. For more information see [Process state \(PSTATE\) in Debug state on page H2-5445](#).

The debugger must save any state that can be corrupted by an exception before executing an instruction that might generate another exception.

Pseudocode description of taking exceptions in Debug state

The pseudocode function [AArch64.TakeException\(\)](#) shows the behavior when the PE takes an exception to an Exception level using AArch64 in Non-debug state. In Debug state, this is replaced with the function [AArch64.TakeExceptionInDebugState\(\)](#).

The pseudocode functions `AArch32.EnterMode()`, `AArch32.EnterHypMode()`, and `AArch32.EnterMonitorMode()` show the behavior when the PE takes an exception to an Exception level using AArch32 in Non-debug state. In Debug state:

- `AArch32.EnterMode()` is replaced with the function `AArch32.EnterModeInDebugState()`.
- `AArch32.EnterHypMode()` is replaced with the function `AArch32.EnterHypModeInDebugState()`.
- `AArch32.EnterMonitorMode()` is replaced with `AArch32.EnterMonitorModeInDebugState()`.

Reset in Debug state

If the PE is reset when in Debug state, it exits Debug state and enters Non-debug reset state. When the PE is in reset state, `EDSCR.STATUS == 0b000010` and writes to `EDITR` are ignored.

———— **Note** —————

If `EDECR.RCE == 1`, meaning that a Reset Catch debug event is programmed, and if halting is allowed on exiting reset state, then on exiting reset state the PE halts and re-enters Debug state. See [Reset Catch debug events on page H3-5492](#). All PE registers have taken their reset values, which might be UNKNOWN.

H2.4.8 Accessing registers in Debug state

Register accesses are unchanged in Debug state. The view of each register is determined by either the current Exception level or the mode, or both, and accesses might be disabled or trapped by controls at a higher Exception level.

General-purpose register access, other than AArch64 state SP access

A single general-purpose register can be read by issuing an MSR instruction through the ITR to write `DBGDTR_EL0` in AArch64 state, or an MCR instruction through the ITR to write `DBGDTRXint` in AArch32 state. The debugger can then read the DTR register or registers through the external debug interface. The reverse sequence writes to a general-purpose register.

[Figure H2-1 on page H2-5468](#) shows the reading and writing of general-purpose registers, other than SP, in Debug state in AArch64 state.

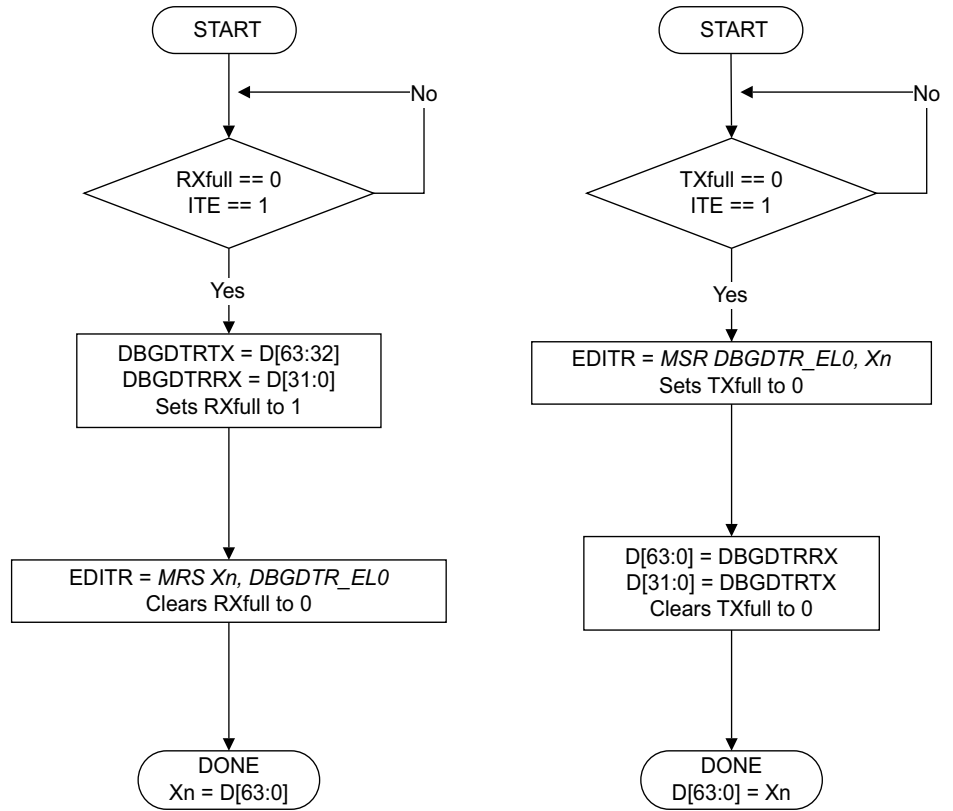

Figure H2-1 Reading and writing general-purpose registers, other than SP, in Debug state in AArch64 state

Figure H2-2 shows the reading and writing of general-purpose registers in Debug state in AArch32 state.

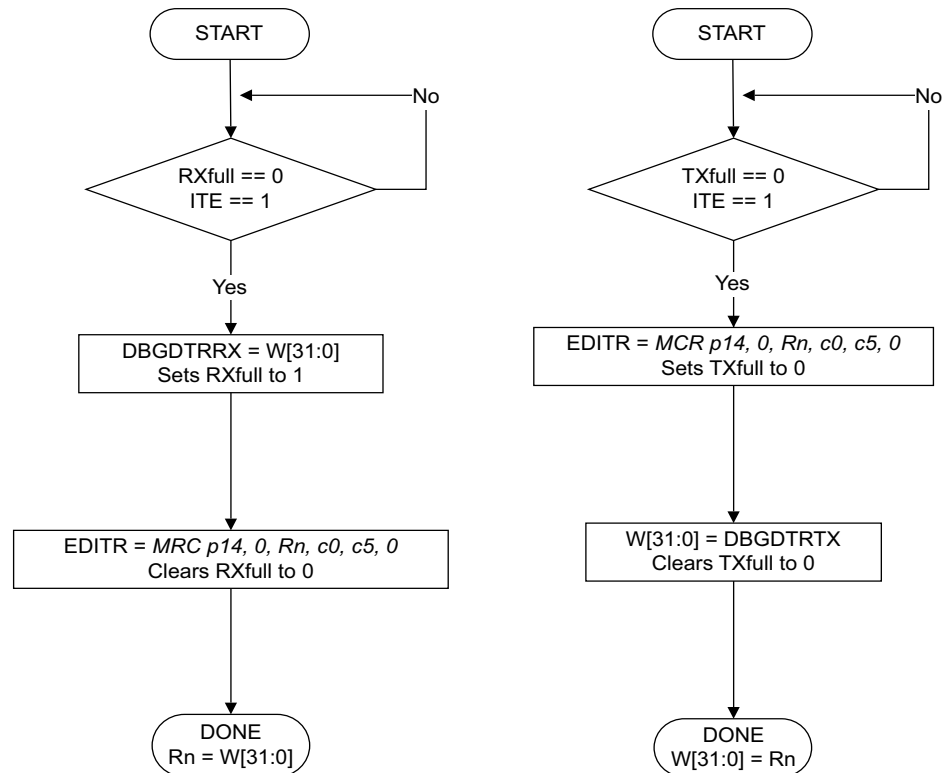

Figure H2-2 Reading and writing general-purpose registers in Debug state in AArch32 state

SIMD and floating-point register, System register, and AArch64 state SP accesses

To read a SIMD and floating-point register or a System register, the debugger must first copy the value into a general-purpose register using:

- An FMOV instruction in AArch64 state or a VMOV instruction in AArch32 state for floating-point transfers to SIMD and FP registers.
- A UMOV instruction in AArch64 state or a VMOV instruction in AArch32 state for SIMD transfers to SIMD and FP registers.
- An MRS instruction in AArch64 state or an MRC instruction in AArch32 state for System registers.
- A MOV Xd,SP instruction for the SP register in AArch64 state.

The debugger can then read out the particular general-purpose register. The reverse sequence writes a register.

PC and PSTATE access

The debugger reads the program counter and PSTATE of the process being debugged through the DLR_ELO and DSPSR_ELO System registers. The actual values of PC and PSTATE cannot be directly observed in Debug state:

- Instructions that are used for direct reads and writes of PC and PSTATE in Non-debug state are UNDEFINED in Debug state.
- On taking an exception, ELR_ELx and SPSR_ELx at the target Exception level are UNKNOWN. They do not record the PC and PSTATE.

PSTATE. {IL, E, M, nRW, EL, SP} are indirectly read by instructions executed in Debug state, but all other PSTATE fields are ignored and cannot be observed. See also:

- [Process state \(PSTATE\) in Debug state on page H2-5445.](#)
- [Executing instructions in Debug state on page H2-5446.](#)

- [Exceptions in Debug state on page H2-5465.](#)

H2.4.9 Accessing memory in Debug state

How the PE accesses memory is unchanged in Debug state. This includes:

- The operation of the MMU, including address translation, tagged address handling, access permissions, memory attribute determination, and the operation of any TLBs.
- The operation of any caches and coherency mechanisms.
- Alignment support.
- Endianness support.
- The Memory order model.

Simple memory transfers

Simple memory accesses can be performed in Debug state by issuing memory access instructions through the ITR and passing data through the DTR registers. [Executing instructions in Debug state on page H2-5446](#) lists the memory access instructions that are supported in Debug state.

Bulk memory transfers

Memory access mode can accelerate bulk memory transfers in Debug state. See [DCC and ITR access modes on page H4-5502](#).

H2.5 Exiting Debug state

The PE exits Debug state when it receives a Restart request trigger event. If `EDSCR.ITE == 0` the behavior of any instruction issued through the ITR in Normal access mode or an operation issued by a DTR access in memory access mode that has not completed execution is `CONSTRAINED UNPREDICTABLE`, and must do one of the following:

- It must complete execution in Debug state before the PE executes the restart sequence.
- It must complete execution in Non-debug state after the PE executes the restart sequence.
- It must be abandoned. This means that the instruction does not execute. Any registers or memory accessed by the instruction are left in an `UNKNOWN` state.

Note

- Implementations can set `EDSCR.ITE` to 1 to indicate that further instructions can be accepted by ITR before the previous instructions have completed. If any previous instruction has not completed and `EDSCR.ITE == 1`, then the PE must complete these instructions in Debug state before executing the restart sequence. `EDSCR.ITE == 0` indicates that the PE is not ready to restart.
- A debugger must observe that any instructions issued through `EDITR` that might generate a synchronous exception, as complete, before issuing a restart request. It can do this by observing the completion of a later instruction, as synchronous exceptions must occur in program order. For example, a debugger can observe that an instruction that reads or writes a DTR register is complete because of its effect on the `EDSCR.{TXfull, RXfull}` flags.

On exiting Debug state, the PE sets the program counter to the address in `DLR`, where:

- If exiting to AArch32 state:
 - Bits[31:1] of the PC are set to the value of bits[31:1] of `DLR`.
 - Bit[0] of the PC is set to a `CONSTRAINED UNPREDICTABLE` choice of 0 or the value of bit[0] in `DLR`.
- If exiting to AArch64 state:
 - Bits[63:56] of `DLR_ELO` might be ignored as part of tagged address handling. See *Address tagging in AArch64 state* on page D4-2006.
 - Otherwise the PC is set from `DLR_ELO`.

Note

Bits[63:32] of `DLR_ELO` are ignored when exiting to AArch32 state.

Exit from Debug state can give rise to a PC alignment fault exception when the program counter is used. Unlike an exception return, this might also happen when returning to AArch32 state. For more information, see *PC alignment checking* on page D1-1793.

On exiting Debug state, `PSTATE` is set from `DSPSR` in the same way that an exception return sets `PSTATE` from `SPSR_ELx`:

- The same illegal exception return checks that apply to an exception return also apply to exiting Debug state. If the return from Debug state is an illegal exception return then the effect on `PSTATE` and the PC is the same as for any other illegal exception return. See *Exception return on page D1-1815* and *Exception return to an Exception level using AArch32 on page G1-4360*.
- The checks on the `PSTATE.IT` bits that apply to exiting Debug state into AArch32 state are the same as those that apply to an exception return. See *Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors*.

- **PSTATE.SS** is copied from **DSPSR.SS** if all of the following hold:
 - **MDSCR_ELI.SS** == 1.
 - The debug target Exception level is using AArch64.
 - Software step exceptions from the restart Exception level are enabled.

Otherwise **PSTATE.SS** is set to 0.

———— **Note** —————

Unlike a return using ERET, **PSTATE.SS** must be restored from **DSPSR.SS** because otherwise it is UNKNOWN.

However, if **OSDLR.DLK** == 1 and **DBGPRCR.CORENPDRQ** == 0, meaning the OS Double Lock is locked in Non-debug state and therefore Software Step exceptions are disabled, but otherwise Software Step exceptions would be enabled from the restart Exception level, it is CONstrained UNPREDICTABLE whether **PSTATE.SS** is copied from **DSPSR.SS**.

- **PSTATE.PAN** is copied from **DSPSR_EL0.PAN**.
- **PSTATE.UAO** is copied from **DSPSR_EL0.UAO**.

———— **Note** —————

- One important difference between Debug state exit and an exception return is that the PE can exit Debug state at EL0. Despite this, the behavior of an exit from Debug state is similar to an exception return. For example, **PSTATE.{D, A, I, F}** is updated regardless of the value of **SCTLR_ELI.UMA**.
- Exit from Debug state has no architecturally-defined effect on the Event Register and Exclusives monitors. An exit from Debug state might set the Event Register or clear the Exclusives monitors, or both, but this is not a requirement and debuggers must not rely on any implementation specific behavior.

The `ExitDebugState()` function is described in [Chapter J1 ARMv8 Pseudocode](#).

Chapter H3

Halting Debug Events

This chapter describes a particular class of debug events. It contains the following sections:

- *Introduction to Halting debug events* on page H3-5474.
- *Halting Step debug events* on page H3-5476.
- *Halt Instruction debug event* on page H3-5486.
- *Exception Catch debug event* on page H3-5487.
- *External Debug Request debug event* on page H3-5490.
- *OS Unlock Catch debug event* on page H3-5491.
- *Reset Catch debug events* on page H3-5492.
- *Software Access debug event* on page H3-5493.
- *Synchronization and Halting debug events* on page H3-5494.

Note

Table K11-1 on page K11-6282 disambiguates the general register references used in this chapter.

H3.1 Introduction to Halting debug events

External debug defines Halting debug events. The following Halting debug events are available in ARMv8:

- [Halting Step debug events on page H3-5476](#).
- [Halt Instruction debug event on page H3-5486](#).
- [Exception Catch debug event on page H3-5487](#).
- [External Debug Request debug event on page H3-5490](#).
- [OS Unlock Catch debug event on page H3-5491](#).
- [Reset Catch debug events on page H3-5492](#).
- [Software Access debug event on page H3-5493](#).

If halting is allowed, a Halting debug event halts the PE. The PE enters Debug state.

In addition, breakpoints and watchpoints might halt the PE if halting is allowed. See [Breakpoint and Watchpoint debug events on page H2-5436](#). Because breakpoints and watchpoints can generate an exception or halt the PE, Breakpoint and Watchpoint debug events are not classified as Halting debug events.

For a definition of Debug state, see [Chapter H2 Debug State](#). For a definition of halting allowed, see [Halting allowed and halting prohibited on page H2-5435](#).

[Debug state entry and debug event prioritization on page H2-5437](#) describes the behavior when multiple debug events are generated by an instruction.

See also [Synchronization and Halting debug events on page H3-5494](#).

[Table H3-1](#) shows the behavior of Breakpoint, Watchpoint, and Halting debug events.

Table H3-1 Summary of debug events and possible outcomes

Debug event type	PE behavior when halting is:	
	Allowed	Prohibited
Breakpoint and Watchpoint debug events on page H2-5436	Halt	See Table D2-1 on page D2-1908 and Table G2-1 on page G2-4457
Halt Instruction debug event on page H3-5486	Halt	UNDEFINED
Software Access debug event on page H3-5493	Halt	Ignored
Exception Catch debug event on page H3-5487	Halt	Ignored
Halting Step debug events on page H3-5476	Halt	Pended
External Debug Request debug event on page H3-5490	Halt	Pended
Reset Catch debug events on page H3-5492	Halt	Pended
OS Unlock Catch debug event on page H3-5491	Pended	Pended

[Table H3-2](#) shows where the pseudocode for each Halting debug event type is located.

Table H3-2 Pseudocode description of Halting debug events

Halting debug event type	Pseudocode
Halt Instruction debug event on page H3-5486	HLT on page C6-628 for AArch64 and HLT on page F5-3121 for AArch32
Software Access debug event on page H3-5493	Pseudocode description of Software Access debug event on page H3-5493
Exception Catch debug event on page H3-5487	Pseudocode description of Exception Catch debug events on page H3-5489

Table H3-2 Pseudocode description of Halting debug events (continued)

Halting debug event type	Pseudocode
<i>External Debug Request debug event on page H3-5490</i>	<i>Pseudocode description of External Debug Request debug events on page H3-5490</i>
<i>Reset Catch debug events on page H3-5492</i>	<i>Pseudocode description of Reset Catch debug event on page H3-5492</i>
<i>OS Unlock Catch debug event on page H3-5491</i>	<i>Pseudocode description of OS Unlock Catch debug event on page H3-5491</i>

H3.2 Halting Step debug events

Halting Step is a debug resource that a debugger can use to make the PE step through code one instruction at a time. This section describes the Halting Step debug events. It is divided into the following sections:

- [Overview of a Halting Step debug event.](#)
- [The Halting Step state machine.](#)
- [Using Halting Step on page H3-5479.](#)
- [Detailed Halting Step state machine behavior on page H3-5479.](#)
- [Synchronization and the Halting Step state machine on page H3-5482.](#)
- [Stepping T32 IT instructions on page H3-5483.](#)
- [Disabling interrupts while stepping on page H3-5484.](#)
- [Syndrome information on Halting Step on page H3-5484.](#)
- [Pseudocode description of Halting Step debug events on page H3-5485.](#)

The architecture describes the behavior as a simple Halting Step state machine. See [The Halting Step state machine.](#)

H3.2.1 Overview of a Halting Step debug event

The behavior of Halting Step is defined by a state machine, shown in [Figure H3-1 on page H3-5478](#). A Halting Step debug event executes a single instruction and then returns control to the debugger. When the debugger software wants to execute a Halting Step:

1. With the PE in Debug state, the debugger activates Halting Step.
2. The debugger signals the PE to exit Debug state and return to the instruction that is to be stepped.
3. The PE executes that single instruction.
4. The PE enters Debug state before executing the next instruction.

However, an exception might be generated while the instruction is being stepped. That is either:

- A synchronous exception generated by the instruction being stepped.
- An asynchronous exception taken before or after the instruction being stepped.

Halting Step has its own enable control bit, [EDECR.SS](#) and [EDES.R.SS](#).

———— Note ————

Because the Halting Step state machine states occur as a result of normal PE operation, the states can be described as both:

- PE states.
- Halting Step states.

H3.2.2 The Halting Step state machine

The state machine states are:

- Inactive** Halting Step is inactive. No Halting Step debug events can be generated, therefore execution is not affected by Halting Step. The PE is in this state whenever either of the following is true:
- Halting Step is disabled. That is, [EDECR.SS](#) is set to 0 and [EDES.R.SS](#) is set to 0.
 - Halting is prohibited. See [Halting the PE on debug events on page H2-5435](#). In this state, if [EDECR.SS](#) is set to 1 then a Halting Step debug event is pending.

In [Figure H3-1 on page H3-5478](#) this state is shown in red.

Active-not-pending

Halting Step is enabled and active. This is the state in which the PE steps an instruction. [EDECR.SS](#) == 1 and [EDES.R.SS](#) == 0. Software must not set [EDECR.SS](#) to 1 unless the PE is in Debug state, otherwise behavior is CONSTRAINED UNPREDICTABLE, as described in [Changing the value of EDECR.SS when not in Debug state on page H3-5483](#).

In [Figure H3-1 on page H3-5478](#) this state is shown in green.

Active-pending

Halting Step is enabled and active. The step has completed, and the PE enters Debug state.
`EDESR.SS == 1`.

In [Figure H3-1 on page H3-5478](#) this state is shown in green.

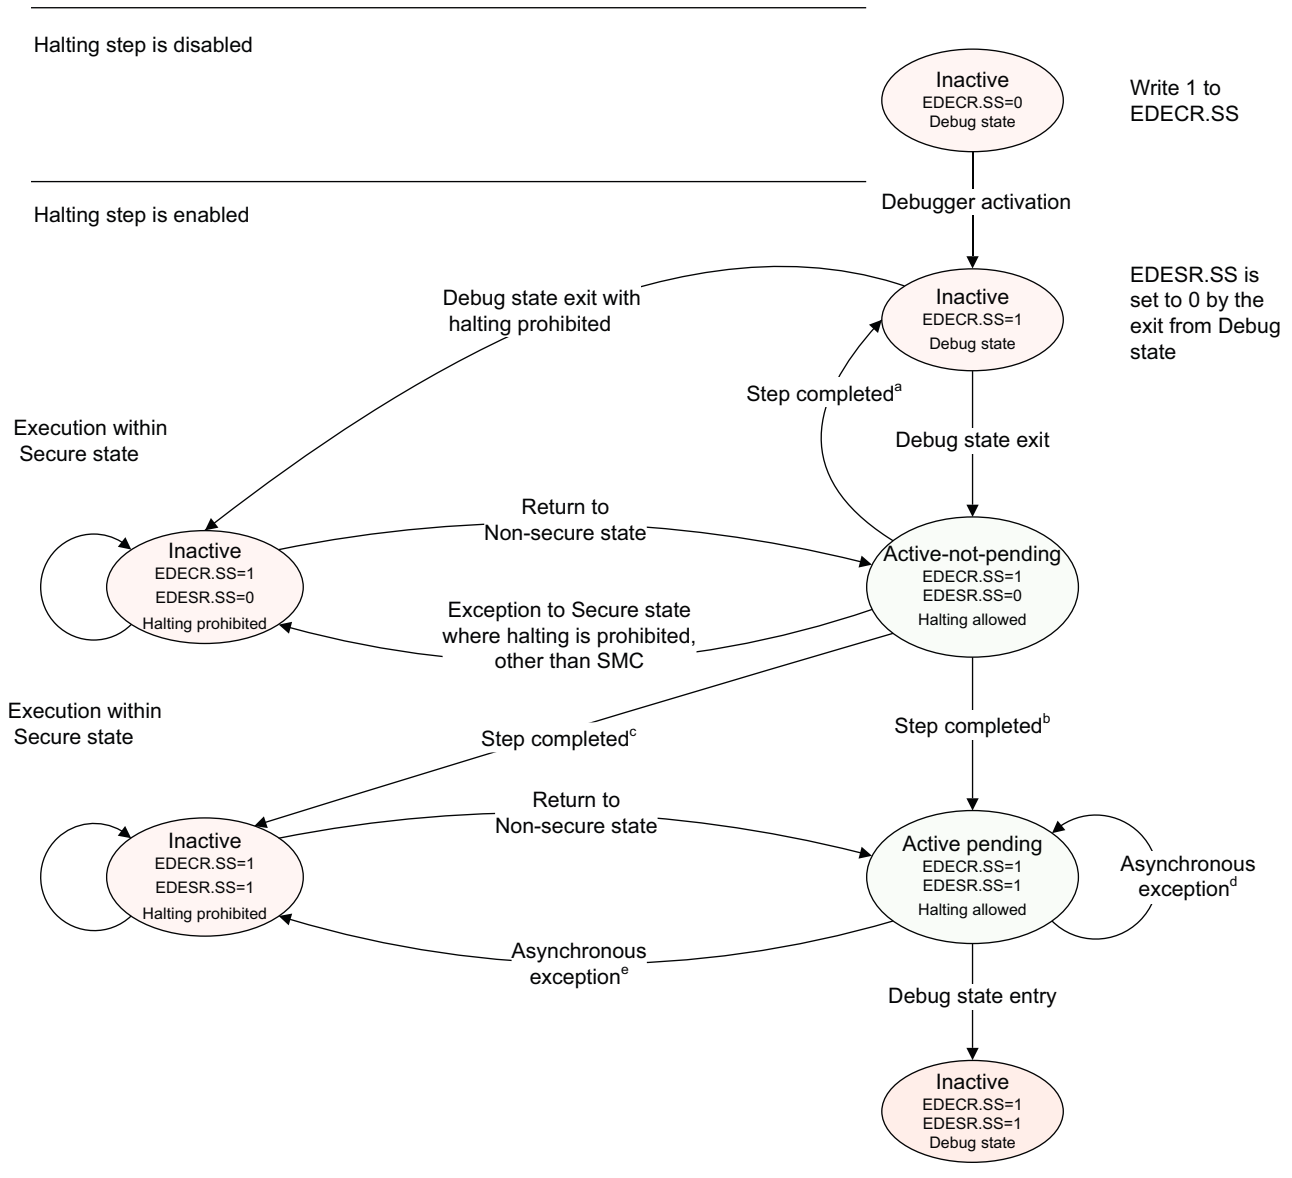

Whenever Halting Step is enabled and active, whether the state machine is in the active-not-pending state or in the active-pending state depends on `EDESR.SS`. [Halting Step state machine states on page H3-5479](#) shows this.

In the simple sequential execution of the program the PE executes the Halting Step state machine, as follows:

1. Initially, Halting Step is inactive.
2. After exiting Debug state, Halting Step is active-not-pending.
3. The PE executes an instruction and Halting Step is active-pending.
4. The pending Debug state entry is taken on the next instruction and the step is complete.

Exceptions and other changes to the PE context can interrupt this sequence.

Figure H3-1 shows a Halting Step state machine.

- Step completed occurs when:
 - A debug event, other than a Halting Step debug event, causes entry into Debug state.
- Step completed occurs when:
 - An instruction is executed without taking an exception.
 - An exception is taken to a state where halting is allowed.
 - A reset.
- Step completed occurs when:
 - An SMC exception is taken to Secure state where halting is prohibited.
- An asynchronous exception taken to a state where halting is allowed.
- An asynchronous exception taken to Secure state where halting is prohibited.

Figure H3-1 Halting Step state machine

———— **Note** ————

Figure H3-1 on page H3-5478 only describes state transitions to and from the inactive state by exit from Debug state, executing an exception return, or taking an exception. Other changes to the PE context, including writes to registers such as [EDECRCR](#) and [OSDLR](#) and changes to the authentication interface can also cause changes to the Halting Step state machine. These can lead to UNPREDICTABLE or CONSTRAINED UNPREDICTABLE behavior. See [Synchronization and the Halting Step state machine on page H3-5482](#).

The following bits control the state machine, as shown in [Table H3-3](#):

- [EDECRCR.SS](#). This is the Halting Step enable bit.

———— **Note** ————

- The [EDECRCR](#) value is preserved over powerdown, meaning that the step active state is maintained over a powerdown event.
- A debugger must only change the value of [EDECRCR.SS](#) when the PE is in Debug state, otherwise behavior is CONSTRAINED UNPREDICTABLE as described in [Changing the value of EDECRCR.SS when not in Debug state on page H3-5483](#).

- [EDESRCR.SS](#). This is the Halting Step debug event pending bit.

[Table H3-3](#) shows the Halting Step state machine states. The letter X in a register column means that the relevant bit can be set to either zero or one.

Table H3-3 Halting Step state machine states

Halting	EDECRCR.SS	EDESRCR.SS	Halting Step state
Prohibited	X	X	Inactive (Halting Step debug even not pending)
Prohibited	X	1	Inactive (Halting Step debug event pending).
Allowed	0	0	Inactive
Allowed	1	0	Active-not-pending
Allowed	X	1	Active-pending

H3.2.3 Using Halting Step

To step a single instruction the PE must be in Debug state:

1. The debugger sets [EDECRCR.SS](#) to 1 to enable Halting step.
2. The debugger signals the PE to exit Debug state with [DLR](#) set to the address of the instruction being stepped. The PE clears [EDESRCR.SS](#) to 0 and the Halting Step state machine enter the active-not-pending state.
3. The PE executes the instruction being stepped.
If an exception is taken to a state where halting is prohibited, then [EDESRCR.SS](#) is always correct for the preferred return address of the exception.
4. The PE enters Debug state before executing the next instruction and the step is complete.

H3.2.4 Detailed Halting Step state machine behavior

The behavior of the Halting Step state machine is described in the following sections:

- [Entering the active-not-pending state on page H3-5480](#).
- [PE behavior in the active-not-pending state on page H3-5480](#).
- [Entering the active-pending state on page H3-5481](#).
- [PE behavior in the active-pending state on page H3-5482](#).
- [PE behavior in the inactive state when in Non-debug state on page H3-5482](#).
- [PE behavior in Debug state on page H3-5482](#).

Entering the active-not-pending state

The PE enters the active-not-pending state:

- By exiting Debug state with `EDECR.SS == 1`.
- By an exception return from a state where halting is prohibited to a state where halting is allowed with `EDECR.SS == 1` and `EDESR.SS == 0`.
- As described in *Synchronization and the Halting Step state machine* on page H3-5482.

PE behavior in the active-not-pending state

When the PE is in the active-not-pending state it does one of the following:

- It executes one instruction and does one of the following:
 - Completes it without generating a synchronous exception.
 - Generates a synchronous exception.
 - Generates a debug event that causes entry to Debug state.
- It takes an asynchronous exception without executing any instruction.
- It takes an asynchronous debug event into Debug state.

If no exception or debug event is generated

If no exception or debug event is generated the PE sets `EDESR.SS` to 1. This means that the Halting Step state machine advances to the active-pending state.

If an exception or debug event is generated

The PE sets `EDESR.SS` according to all of the following:

- The type of exception.
- The target Exception level of the exception.
- If the exception is taken to Secure state, whether halting is prohibited in Secure state.
 - This is determined by the result of `ExternalSecureInvasiveDebugEnabled()`.

If an exception or debug event is generated, the PE sets `EDESR.SS` to 1 if one of the following applies:

- A synchronous exception is generated by the instruction and one of the following applies:
 - The exception is taken to EL1 or EL2.
 - The exception is taken to EL3, it is not an SMC exception, and `ExternalSecureInvasiveDebugEnabled() == TRUE`.
 - The exception is an SMC exception.
- An asynchronous exception is generated before executing an instruction and this is either:
 - Taken to EL1 or EL2.
 - Taken to EL3 and `ExternalSecureInvasiveDebugEnabled() == TRUE`.
- A PE reset occurs.

Otherwise `EDESR.SS` is unchanged. This happens when:

- No instruction is executed because either:
 - An asynchronous exception is taken to EL3 and `ExternalSecureInvasiveDebugEnabled() == FALSE`.
 - An asynchronous debug event causes entry to Debug state.
- An instruction is executed and either:
 - Generates a synchronous exception other than an SMC exception which is taken to EL3, and `ExternalSecureInvasiveDebugEnabled() == FALSE`.

- Generates a synchronous debug event and causes entry to Debug state.

If halting is prohibited after taking the exception or debug event, then the Halting Step state machine advances to the inactive state. Otherwise the Halting Step state machine advances to the active-pending state.

———— **Note** —————

The underlying criteria for the value of `EDESR.SS` on an exception are:

- Whether halting is allowed at the target of the exception. If halting is allowed, the PE must step into the exception. If halting is prohibited, the PE must step over the exception.
- Whether the preferred return address of the exception is the instruction itself or the next instruction, if the PE steps over the exception.

Table H3-4 shows the behavior of the active-not-pending state. The letter X indicates that `ExternalSecureInvasiveDebugEnabled()` can be either TRUE or FALSE.

Table H3-4 Summary of active-not-pending state behavior

Event	Target Exception level	<code>ExternalSecureInvasiveDebugEnabled()</code>	Value written to <code>EDESR.SS</code>
No exception or debug event	Not applicable	X	1
SMC exception	EL3	X	1
Reset	Highest	X	1
Exception, other than SMC exception	EL1	X	1
	EL2	X	1
	EL3	TRUE	1
		FALSE	Unchanged
Debug event	Debug state	X	Unchanged

Entering the active-pending state

The PE enters the active-pending state by one of the following:

- From the active-not-pending state by:
 - Executing an instruction without taking an exception.
 - Taking an exception so that the PE remains in a state where halting is allowed.
- An exception return from a state where halting is prohibited when `EDESR.SS == 1`.

———— **Note** —————

That is, an exception return from Secure state with `ExternalSecureInvasiveDebugEnabled() == FALSE` to Non-secure state with `ExternalInvasiveDebugEnabled() == TRUE`.

- A reset when the value of `EDEC.R.SS == 1`, regardless of the state the PE was in before the reset occurred.
- From the active-pending state by taking an asynchronous exception to a state where halting is allowed.
- Following the description in *Synchronization and the Halting Step state machine* on page H3-5482.

PE behavior in the active-pending state

When the PE is in the active-pending state, it enters Debug state before executing an instruction.

The entry into Debug state has higher priority than all other types of synchronous debug event and synchronous exception. However, the architecture does not define the prioritization of this Debug state entry with respect to any unmasked pending asynchronous exception. If an asynchronous exception is prioritized over the entry to Debug state, then EDESR.SS is unchanged.

For more information on the prioritization of debug events, see [Debug state entry and debug event prioritization on page H2-5437](#).

PE behavior in the inactive state when in Non-debug state

EDESR.SS is not updated by the execution of an instruction or the taking of an exception when Halting Step is inactive. This means that EDESR.SS is not changed by an exception handled in a state where halting is prohibited.

On return to a state where halting is allowed, the Halting Step state machine is restored either to the active-pending state or the active-not-pending state, depending on the value of EDESR.SS. The return to a state where halting is allowed is normally by an exception return, which is a *Context synchronization event*.

See also [Synchronization and the Halting Step state machine](#).

PE behavior in Debug state

Halting Step is inactive in Debug state because halting is prohibited, see [Halting allowed and halting prohibited on page H2-5435](#).

Entry to Debug state does not change EDESR.SS.

EDESR.SS is cleared to 0 on exiting Debug state as the result of a restart request. If EDECR.SS == 1, Halting Step enters the active-not-pending state.

———— Note —————

This means that EDESR.SS is never cleared to 0 by the execution of an instruction in Debug state, or by taking an exception when in Debug state as described in [PE behavior in the active-not-pending state on page H3-5480](#), because the Halting Step state machine is not in the active-not-pending state. EDESR.SS can be cleared by a write to EDESR, see the register description.

However, if the PE exits Debug state as the result of a PE reset and EDECR.SS == 1, then Halting Step immediately enters the active-pending state, as EDESR.SS is set to the value of EDECR.SS.

H3.2.5 Synchronization and the Halting Step state machine

The Halting Step state machine also changes state if:

- Halting becomes allowed or prohibited other than by exit from Debug state, an exception return, or taking an exception. This means that halting becomes allowed or prohibited because:
 - The security state changes without an exception return. See [State and mode changes without explicit context synchronization events on page G2-4519](#).
 - The external authentication interface changes.
 - The OS Double Lock status, DoubleLockStatus(), changes.
- A write to EDECR when the PE is in Non-debug state changes the value of EDECR.SS.

———— Note —————

Behavior is CONSTRAINED UNPREDICTABLE if the value of EDECR.SS is changed when the PE is in Non-debug state, see [Changing the value of EDECR.SS when not in Debug state on page H3-5483](#).

- A write to `EDESR` when the PE is in Non-debug state clears `EDESR.SS` to 0.

These operations are guaranteed to take effect only after a *Context synchronization event*. If the instruction being stepped generates a *Context synchronization event*, then the PE might use the old or new state.

The PE must perform the required behavior of the new state before or immediately following the next *Context synchronization event*, but it is not required to do so immediately. This means that the PE can perform the required behavior of the old state before the next *Context synchronization event*. This is illustrated in [Example H3-1](#) and [Example H3-2](#).

Example H3-1 Synchronization requirements 1

`EDECR.SS` is set to 1 in Debug state, requesting the active-not-pending state on exit from Debug state. On exit from Debug state the PE immediately takes an exception to Secure state. `ExternalSecureInvasiveDebugEnabled() == FALSE`, meaning that halting is prohibited in Secure state. The PE does not step any instructions but executes the software in Secure state as normal. `EDESR.SS` remains set to 0. If `ExternalSecureInvasiveDebugEnabled()` subsequently becomes TRUE, meaning that halting is now allowed, the PE must perform the required behavior of the active-not-pending state before or immediately following the next *Context synchronization event*, but it is not required to do so immediately.

Example H3-2 Synchronization requirements 2

`EDECR.SS` is set to 1 in Debug state. On exit from Debug the PE executes an MSR instruction that sets `OSDLR_EL1.DLK` to 1 and `DoubleLockStatus()` becomes TRUE. This change requires a *Context synchronization event* to guarantee its effect, meaning it is CONstrained UNPREDICTABLE whether:

- Halting is allowed:
 - The PE enters Debug state on the next instruction.
- Halting is prohibited:
 - The PE does not enter Debug state.

The value in `EDESR.SS` depends on whether halting was allowed or prohibited when the write to `OSDLR_EL1.DLK` completed, and so it might be 0 or 1. If a second MSR instruction clears `OSDLR_EL1.DLK` to 0, the PE must perform the required behavior of the state indicated by `EDESR.SS` before or immediately following the next *Context synchronization event*, but it is not required to do so immediately.

See also [Synchronization and Halting debug events on page H3-5494](#).

Changing the value of `EDECR.SS` when not in Debug state

If software changes the value of `EDECR.SS` when the PE is not in Debug state then behavior is CONstrained UNPREDICTABLE, and one or more of the following behaviors occurs:

- The value of `EDECR.SS` becomes UNKNOWN.
- The state of the Halting Step state machine becomes UNKNOWN.
- On a reset of the PE, the value of `EDECR.SS` and the state of the Halting Step state machine are UNKNOWN.

H3.2.6 Stepping T32 IT instructions

In an implementation that supports the ITD control, the architecture permits a combination of one T32 IT instruction and another 16-bit T32 instruction to be treated as a single 32-bit instruction when the value of the ITD field that applies to the current Exception level is 1.

For the purpose of stepping an item, it is IMPLEMENTATION DEFINED whether:

- The PE considers such a pair of instructions to be one instruction.

- The PE considers such a pair of instructions be two instructions.

It is IMPLEMENTATION DEFINED whether this behavior depends on the value of the applicable ITD bit. For example:

- The debug logic might consider such a pair of instructions as one instruction, regardless of the state of the applicable ITD field.
- The debug logic might consider such a pair of instructions as two instructions, regardless of the state of the applicable ITD field.
- The debug logic might consider such a pair of instructions as one instruction when the value of the applicable ITD field is 1, and as two instructions when the value of the ITD field is 0.

An implementation that does not support the ITD control behaves as if the value of the ITD field is 0.

The ITD control fields are:

HSTCLR.ITD Applies to execution at EL2 when EL2 is using AArch32.

SCTLR.ITD Applies to execution at EL0 or EL1 when EL1 is using AArch32.

SCTLR_EL1.ITD

Applies to execution at EL0 using AArch32 when EL1 is using AArch64.

H3.2.7 Disabling interrupts while stepping

When using Halting Step, the sequence of entering Debug state, interacting with the debugger, and then exiting Debug state for each instruction reduces the rate at which the PE executes instructions. However, the rate at which certain interrupts, such as timer interrupts, are generated might be fixed by the system. This means it might be necessary to disable interrupts while using Halting Step by setting **EDSCR.INTdis**, to allow the code being debugged to make forward progress.

H3.2.8 Syndrome information on Halting Step

Three **EDSCR.STATUS** encodings record different scenarios for entering Debug state on a Halting Step debug event:

Halting Step, normal

An instruction other than a Load-Exclusive instruction was stepped.

Halting Step, exclusive

A Load-Exclusive instruction was stepped.

Halting Step, no syndrome

The syndrome data is not available.

If the PE enters Debug state due to a Halting Step debug event immediately after stepping an instruction in the active-not-pending state, **EDSCR.STATUS** is set to either:

- Halting Step, normal, if the stepped instruction was not a Load-Exclusive instruction.
- Halting Step, exclusive, if the stepped instruction was a Load-Exclusive instruction.

If the stepped instruction was a conditional Load-Exclusive instruction that failed its Condition code check, **EDSCR.STATUS** is set to a CONSTRAINED UNPREDICTABLE choice of Halting Step, normal, or Halting Step, exclusive.

Otherwise the PE enters Debug state without stepping an instruction. This means that the Halting Step state machine enters the active-pending state directly from the inactive state, without going through active-not-pending state. In this case, **EDSCR.STATUS** is set to Halting Step, no syndrome. This happens when:

- The PE enters directly into the active-pending state on an exception return to Non-secure state from EL3 when Halting is prohibited in Secure state.
- The active-pending state is entered for other reasons. See [Synchronization and the Halting Step state machine on page H3-5482](#)

In addition, `EDSCR.STATUS` is set to one of a CONSTRAINED UNPREDICTABLE choice if:

- The instruction being stepped generated a synchronous exception, or a pending asynchronous exception was taken before the instruction was executed.

In this case `EDSCR.STATUS` is set to a CONSTRAINED UNPREDICTABLE choice of:

- Halting Step, no syndrome, or Halting Step, normal, if the stepped instruction was not a Load-Exclusive instruction.
 - Halting Step, no syndrome, or Halting Step, exclusive, if the stepped instruction was a Load-Exclusive instruction.
- The instruction that was stepped was an exception return instruction or an ISB. As these instructions are not in the Load-Exclusive instructions, `EDSCR.STATUS` is set to a CONSTRAINED UNPREDICTABLE choice of Halting Step, no syndrome or Halting Step, normal.
 - The PE enters directly into the active-pending state on reset because `EDECR.SS` is set to 1. `EDSCR.STATUS` is set to a CONSTRAINED UNPREDICTABLE choice of Halting Step, no syndrome or Halting Step, normal.

In all cases, if `EDSCR.STATUS` is not set to Halting Step, no syndrome, then it must indicate whether the stepped instruction was a Load-Exclusive instruction by setting `EDSCR.STATUS` to Halting Step, normal or Halting Step, exclusive.

———— **Note** —————

In an implementation that always sets `EDSCR.STATUS` to Halting Step, no syndrome is not compliant.

H3.2.9 Pseudocode description of Halting Step debug events

There are two pseudocode functions for Halting Step debug events:

- `RunHaltingStep()`. This is called after an instruction has executed and any exception generated by the instruction is taken. It is also called after taking a reset before executing any instructions. That is, reset is treated like an asynchronous exception, even if `EDECR.RCE == 1`. `RunHaltingStep()` affects the next instruction.
- `CheckHaltingStep()`. This is called before the next instruction is executed. If a step is pending, it generates the debug event.

H3.3 Halt Instruction debug event

A Halt Instruction debug event is generated when `EDSCR.HDE == 1`, halting is allowed, and the PE executes the Halt instruction, HLT.

The pseudocode for Halt Instruction debug events is described in [HLT on page C6-628](#) for A64 and [HLT on page F5-3121](#) for A32 and T32.

HLT never generates a debug exception. It is treated as UNDEFINED if `EDSCR.HDE == 0`, or if halting is prohibited.

———— **Note** —————

A debugger can replace a program instruction with a Halt instruction to generate a Halt Instruction debug event. Debuggers that use the HLT instruction must be aware of the ARMv8-A rules for concurrent modification of executable code, CMODX. The rules for concurrent modification and execution of instructions do not allow one thread of execution or an external debugger to replace an instruction with an HLT instruction when these same instructions are being executed by a different thread of execution. See [Concurrent modification and execution of instructions on page B2-84](#).

The T32 HLT instruction is unconditionally executed inside an IT block, even when it is treated as UNDEFINED. The A32 HLT instruction is CONSTRAINED UNPREDICTABLE if the Condition code field is not `0b1110`, with the set of behaviors the same as for BKPT. See [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

———— **Note** —————

The HLT instruction is part of the external debug solution for ARMv8-A. As such, the presence of the HLT instruction is not indicated in the ID registers. In particular, the AArch32 System register `ID_ISAR0`. Debug does not indicate the presence of the HLT instruction.

H3.3.1 HLT instructions as the first instruction in a T32 IT block

In an implementation that supports the ITD control, the architecture permits a combination of one T32 IT instruction and certain other 16-bit T32 instruction to be treated as a single 32-bit instruction when the value of the ITD field that applies to the current Exception level is 1.

The T32 HLT instruction cannot be combined with an IT instruction in this way. In an implementation that supports the ITD control, if the first instruction in an IT block is an HLT instruction, then the behavior of the instruction depends on the value of the applicable ITD field:

- If the value of the ITD field is 1, then the combination is treated as UNDEFINED and an Undefined Instruction exception is generated either by the IT instruction or by the HLT instruction.
- If the value of the ITD field is 0, then the HLT instruction unconditionally executed.

An implementation that does not support the ITD control behaves as if the value of the ITD field is 0.

To set an Halt Instruction debug event on the first instruction of an IT block, debuggers must replace the IT instruction with an HLT instruction to ensure consistent behavior.

The ITD control fields are:

HSCTLR.ITD Applies to execution at EL2 when EL2 is using AArch32.

SCTLR.ITD Applies to execution at EL0 or EL1 when EL1 is using AArch32.

SCTLR_EL1.ITD

Applies to execution at EL0 using AArch32 when EL1 is using AArch64.

———— **Note** —————

An HLT instruction is always unconditional, even within an IT block.

H3.4 Exception Catch debug event

Exception Catch debug events:

- Are generated when the corresponding bit in the Exception Catch Control Register, [EDEC](#)CR, is set to 1 on all entries to a given Exception level. This means:
 - Exceptions taken to the Exception level.
 - Exception returns to the Exception level.
- Are taken synchronously, after entry to the Exception level.
- Ignore the Execution state of the target Exception level.
- Are ignored if halting is prohibited.

From ARMv8.2 the definition is extended to include generation of Exception Catch debug events on reset entry, see [Exception Catch debug events from ARMv8.2 on page H3-5489](#).

The [EDEC](#)CR contains two sets of fields:

- One set for Non-secure state.
- One set for Secure state.

Each set of fields control generation of Exception Catch debug events:

- On exception entry [and, from ARMv8.2, on reset entry](#).
- On exception return.

Each field within each set contains one bit for each Exception level in that state. Bits corresponding to Exception levels that are not implemented are RES0. See [EDEC](#)CR, [External Debug Exception Catch Control Register on page H9-5622](#).

———— Note —————

- [EDEC](#)CR does not replace [DBG](#)VCR:
 - [DBG](#)VCR is retained in AArch32 state for backwards compatibility.
 - [DBG](#)VCR is ignored in AArch64 state and never generates entries to Debug state.
 - [DBG](#)VCR cannot be accessed by the external debug interface.
- [EDEC](#)CR is only visible as [OSEC](#)CR_EL1 by System register instructions in AArch64 state, and as [DBG](#)OSECCR by System register access instructions in AArch32 state, when the OS Lock is locked to allow software to save and restore it over a powerdown.
- Exception Catch debug events are not disabled when the OS Lock is locked.

For an Exception Catch debug event generated after taking an exception to a trapped Exception level:

- The PE must not fetch instructions from the vector address before entering Debug state, if address translation is disabled in the translation regime at the target Exception level.
- On entering Debug state:
 - The current Exception level is the target Exception level of the exception.
 - The ELR, SPSR, ESR, and other syndrome registers contain information about the exception.
 - [DLR](#) contains the exception vector address [or, from ARMv8.2, the reset address](#).

H3.4.1 Prioritization of Exception Catch debug events

The following rules define the prioritization of Exception Catch debug events:

- It is IMPLEMENTATION DEFINED whether Exception Catch debug events are higher or lower priority than each of [Software Step exceptions](#) and [Halting Step debug events](#).

- Exception Catch debug events are higher priority than all synchronous exceptions other than [Software Step exceptions](#).
- Exception Catch debug events are lower priority than [Reset Catch debug events](#).

———— **Note** —————

As described in [Synchronous exception prioritization for exceptions taken to AArch64](#) on page D1-1827, an exception trapping form of a Vector Catch debug event might generate a second debug exception as part of the exception entry, before the Exception Catch debug event is taken. See [Vector Catch exceptions](#) on page D2-1955 or [Vector Catch exceptions](#) on page G2-4510.

A second unmasked asynchronous exception can be taken before the PE enters Debug state. If this second exception does not generate an Exception Catch debug event, the exception handler executed at the higher Exception level later returns to the trapped Exception level, causing the Exception Catch debug event to be generated again.

See also [Debug state entry and debug event prioritization](#) on page H2-5437.

From ARMv8.2, when an Exception Catch debug event is generated on exception entry, the PE must enter Debug state as part of the exception entry:

- After the exception entry has updated the program counter, PSTATE and syndrome registers for the exception.
- Before the first instruction at the handler is executed.
- Before any asynchronous or lower priority synchronous exception or debug event is taken at the first instruction in the exception handler.

From ARMv8.2, when an Exception Catch debug event is generated on exception return, the PE must enter Debug state:

- After the exception return has updated the program counter and PSTATE.
- Before the execution of the first instruction at the return address is completed.

———— **Note** —————

From ARMv8.2, there is no prioritization between asynchronous exceptions, asynchronous debug events, and an Exception Catch debug event generated on an exception return.

H3.4.2 CONSTRAINED UNPREDICTABLE generation of Exception Catch debug events

When [ARMv8.2-Debug is not implemented](#), the PE is executing code at a given Exception level, and the corresponding [EDECCR](#) bit is 1, it is CONSTRAINED UNPREDICTABLE whether an Exception Catch debug event is generated.

———— **Note** —————

It is possible to generate Exception Catch debug events:

- As a trap on all instruction fetches from the trapped Exception level as part of an instruction fetch.
- On entry to the Exception level, as described in [Detailed Halting Step state machine behavior](#) on page H3-5479.

This is similar to the implementation options allowed for Vector Catch debug events. The architecture does not require that the event is generated following an ISB operation executed at the Exception level.

Examples of this are:

- If the debugger writes to [EDECCR](#) so that the current Exception level is trapped.
- If the OS restore code writes to [OSECCR](#) so that the current Exception level is trapped.

- If the code executing in AArch32 state changes the Exception level or security state other than by an exception return, and the target Exception level is trapped. See [State and mode changes without explicit context synchronization events](#) on page G2-4519.

When ARMv8.2-Debug is implemented, there are no CONSTRAINED UNPREDICTABLE cases that are permitted to generate Exception Catch debug events.

H3.4.3 Exception Catch debug events from ARMv8.2

From ARMv8.2, the definition of Exception Catch debug events is extended so that Exception Catch debug events can be generated from:

- Exception entry.
- Reset entry.
- Exception return.

It is IMPLEMENTATION DEFINED whether a reset into an Exception level generates an Exception Catch debug event.

Exception catch debug events are taken synchronously, after the exception or reset entry or the exception return has been processed by the PE.

For exception returns, the final Exception level of the exception return determines whether an Exception Catch debug event is generated. On an illegal exception return an Exception Catch debug event is generated only if EDECCR is programmed to generate an Exception Catch debug event for an exception return to the current Exception level.

H3.4.4 Examples of Exception Catch debug events

If EDECCR == 0x20, meaning that the Exception Catch debug event is enabled for Non-secure EL1, then the following exceptions generate Exception Catch debug events:

- An exception taken from Non-secure EL0 to Non-secure EL1.
- An exception return from EL2 to Non-secure EL1.
- An exception return from EL3 to Non-secure EL1.

For example, on taking a Data Abort exception from Non-secure EL0 to Non-secure EL1, using AArch64:

- ELR_EL1 and SPSR_EL1 are written with the preferred return address and PE state for a return to EL0.
- ESR_EL1 and FAR_EL1 are written with the syndrome information for the exception.
- DLR_EL0 is set to VBAR_EL1 + 0x400, the synchronous exception vector.
- DSPSR_EL0 is written with the PE state for an exit to EL1.

The following do not generate Exception Catch debug events:

- An exception taken from Non-secure EL0 to EL2 or EL3.
- An exception return from EL2 to Non-secure EL0.
- An exception taken from Secure EL0 to Secure EL1.
- An exception return from EL3 to Secure EL1.

H3.4.5 Pseudocode description of Exception Catch debug events

The pseudocode function `CheckExceptionCatch()` is described in [Chapter J1 ARMv8 Pseudocode](#).

H3.5 External Debug Request debug event

External Debug Request debug events are asynchronous debug events.

An External Debug Request debug event is generated when signaled by the embedded cross-trigger. See [Chapter H5 The Embedded Cross-Trigger Interface](#).

———— **Note** —————

ARMv8-A requires the implementation of an embedded cross-trigger.

An implementation might also support IMPLEMENTATION DEFINED ways of generating an External Debug Request debug event.

H3.5.1 Synchronization and External Debug Request debug events

An External Debug Request debug event that is asserted before a [Context synchronization event](#) is taken and the PE enters Debug state before the first instruction following the [Context synchronization event](#) completes its execution, provided that halting is allowed after completion of the [Context synchronization event](#).

An External Debug Request debug event that is being asserted when the PE comes out of reset is taken, and the PE enters Debug state before the first instruction after the reset completes its execution, provided that halting is allowed when the PE exits reset state.

If the first instruction after the [Context synchronization event](#) or after coming out of reset generates a synchronous exception then the architecture does not define the order in which the debug event and the exception or exceptions are taken.

Otherwise, when halting is allowed, External Debug Request debug events must be taken in finite time, without requiring the synchronization of any necessary change to the external authentication interface.

———— **Note** —————

These rules are based on the rules that apply when taking asynchronous exceptions. See [Asynchronous exception types, routing, masking and priorities](#) on page D1-1834.

If an unmasked External Debug Request debug event was pending but is changed to not pending before it is taken, then the architecture permits the External Debug Request debug event to be taken, but does not require this to happen. If the External Debug Request debug event is taken then it must be taken before the first [Context synchronization event](#) after the External Debug Request debug event was changed to not pending.

[Example H3-3](#) shows an example of the synchronization requirements.

Example H3-3 Synchronization requirements

Secure software locks up in a tight loop, so it executes indefinitely without any synchronization operations. An External debug request must be able to break the PE out of that loop. This is a requirement even if **DBGEN** or **SPIDEN** or both are LOW on entry to the loop, meaning that halting is prohibited, and are only asserted HIGH later.

H3.5.2 Pseudocode description of External Debug Request debug events

The `ExternalDebugRequest()` function is described in [Chapter J1 ARMv8 Pseudocode](#).

H3.6 OS Unlock Catch debug event

An OS Unlock Catch debug event is generated when `EDECR.OSUCE == 1` and the state of the OS Lock changes from locked to unlocked.

When the OS Lock is unlocked, the PE sets `EDESR.OSUC` to 1 if `EDECR.OSUCE` is set to 1 and the PE is in Non-debug state, meaning the OS Unlock Catch debug event becomes pending. However, this is an indirect write to `EDESR.OSUC`, meaning the OS Unlock Catch debug event is not guaranteed to be taken before a subsequent context synchronization event. If the PE enters Debug state or `EDECR.OSUCE` is cleared to 0 before `EDESR.OSUC` becomes set to 1, then `EDESR.OSUC` might not be set.

OS Unlock Catch debug events are not generated if the OS Lock is unlocked when the PE is in Debug state. See also:

- [Synchronization and Halting debug events on page H3-5494.](#)
- [EDECR, External Debug Execution Control Register on page H9-5626.](#)
- [EDESR, External Debug Event Status Register on page H9-5628.](#)

`EDESR.OSUC` is cleared to 0 on a Warm reset and on exiting Debug state.

H3.6.1 Using the OS Unlock Catch debug event

If the debugger attempts to access a debug register when the Core power down domain is completely off or in a low-power state in which the core power domain registers cannot be accessed, and that access returns an error, then the debugger must retry the access. However, if the Core power domain is regularly powered down, this can lead to unreliable debugger behavior.

The debugger can program a Reset Catch debug event to halt the PE when it has powered up, and can program the debug registers from Debug state. However, if the PE boot software restores the debug registers, as described in [Debug OS Save and Restore sequences on page H6-5541](#), then newly written values are overwritten by the restore sequence.

The debugger can program an OS Unlock Catch debug event to halt the PE after the restore sequence has completed, and program the debug registers from Debug state.

H3.6.2 Pseudocode description of OS Unlock Catch debug event

The `CheckOSUnlockCatch()` function is called when the OS Lock is unlocked.

The `CheckPendingOSUnlockCatch()` function is called before an instruction is executed. If an OS Unlock Catch is pending, it generates the debug event.

H3.7 Reset Catch debug events

A Reset Catch debug event is generated when `EDECR.RCE == 1` and the PE exits reset state. When the Reset Catch debug event is generated, it is recorded by setting `EDESR.RC` to 1.

If halting is allowed when the event is generated, the Reset Catch debug event is taken immediately and synchronously. On entering Debug state, `DLR` has the address of the reset vector. The PE must not fetch any instructions from memory.

Otherwise, the Reset Catch debug event is pended and taken when halting is allowed. See also:

- [Synchronization and Halting debug events](#) on page H3-5494.
- [EDECR, External Debug Execution Control Register](#) on page H9-5626.
- [EDESR, External Debug Event Status Register](#) on page H9-5628.

This means that `EDESR.RC` is set to the value of `EDECR.RCE` on a Warm reset. `EDESR.RC` is cleared to 0 on exiting Debug state.

H3.7.1 Pseudocode description of Reset Catch debug event

The `CheckResetCatch()` function is called after reset before executing any instruction.

The `CheckPendingResetCatch()` function is called before an instruction is executed. If a Reset Catch is pending, it generates the Reset Catch debug event.

H3.8 Software Access debug event

When the value of `EDSCR.TDA == 1`, software access to the following debug AArch64 and AArch32 System registers cause a trap to Debug state:

- The Breakpoint Value Registers, [DBGBVR](#).
- The Breakpoint Control Registers, [DBGBCR](#).
- The Watchpoint Value Registers, [DBGWVR](#).
- The Watchpoint Control Registers, [DBGWCR](#).

However, `EDSCR.TDA` is ignored if one of:

- The value of `OSLSR.OSLK == 1`, meaning that the OS Lock is locked.
- Halting is prohibited. See *Halting allowed and halting prohibited* on page H2-5435.
- The register access generates an exception.

Note

- `DBGPRCR.CORENPDRQ` (Core No-powerdown Request), DCC registers, and CLAIM tag bits are also shared, but are deliberately excluded from this list.
 - The only accesses that generate a trap are:
 - Accesses to System registers in AArch64 state.
 - Accesses to System registers in the (coproc==0b1110) encoding space in AArch32 state.Accesses to the external debug interface by a PE are not trapped.
-

H3.8.1 Pseudocode description of Software Access debug event

The `CheckSoftwareAccessToDebugRegisters()` function is described in [Chapter J1 ARMv8 Pseudocode](#).

H3.9 Synchronization and Halting debug events

The behavior of external debug depends on:

- Indirect reads of:
 - External debug registers.
 - System registers, including system debug registers.
 - Special-purpose registers.
- The state of the external authentication interface.

For some registers, all read and write accesses that update the register occur in program order, without any additional synchronization, but others require an explicit *Context synchronization event*. For more information on the synchronization of register updates see:

- [Synchronization requirements for AArch64 System registers on page D7-2191](#).
- [Synchronization of changes to the external debug registers on page H8-5554](#).
- [State and mode changes without explicit context synchronization events on page G2-4519](#).

Changes to the external authentication interface do not require explicit synchronization to affect External Debug Request debug events. See [Synchronization and External Debug Request debug events on page H3-5490](#).

For changes that require explicit synchronization, it is CONSTRAINED UNPREDICTABLE whether instructions between the change and the *Context synchronization event* observe the old state or the new state.

This means that any change to these registers or the external authentication interface requires explicit synchronization by a *Context synchronization event* before the change takes effect. This ensures that for instructions appearing in program order after the change, the change affects the following:

- The generation and behavior of Breakpoint and Watchpoint debug events. See [Synchronization and debug exceptions on page D2-1970](#) for exceptions taken from AArch64 state, or [Synchronization and debug exceptions on page G2-4518](#) for exceptions taken from AArch32 state.
- The generation of all Halting debug events by instructions.
- Taking a pending Halting debug event or other asynchronous Debug event. See:
 - [Pending Halting debug events](#).
 - [Synchronization and External Debug Request debug events on page H3-5490](#).
- The behavior of the Halting Step state machine. See [Synchronization and the Halting Step state machine on page H3-5482](#).

H3.9.1 Pending Halting debug events

A Halting debug event might be pending:

1. If Halting Step of an instruction sets [EDES.RC](#) to 1, and halting is prohibited following the step, then the Halting Step state machine is inactive but a Halting Step debug event is pending.
2. If a Reset Catch debug event sets [EDES.RC](#) to 1, and halting is prohibited following reset, then a Reset Catch debug event is pending.
3. If an OS Unlock Catch debug event sets [EDES.OSUC](#) to 1, then an OS Unlock Catch debug event is pending.

Pending Halting debug events are taken asynchronously when halting is allowed.

Pending Halting debug events are discarded by a Cold reset. The debugger can also force a pending event to be dropped by writing to [EDES](#).

Any Halting debug event that is observed as pending in the [EDES](#) before a *Context synchronization event* is taken and the PE enters Debug state before the first instruction following the *Context synchronization event* completes its execution. This is only possible if halting is allowed after completion of the *Context synchronization event*.

If the first instruction after the *Context synchronization event* generates a synchronous exception then the architecture does not define the order in which the debug event and the exception or exceptions are taken, unless both:

- A Halting Step debug event is pending. `EDESR.SS == 1`.
- The *Context synchronization event* is an exception return from a state where halting is prohibited to a state where halting is allowed.

———— **Note** —————

This applies to an exception return from Secure state with `ExternalSecureInvasiveDebugEnabled() == FALSE` to Non-secure state with `ExternalInvasiveDebugEnabled() == TRUE`.

In this case the order in which the debug events are handled is specified to avoid a double-step. See *Entering the active-pending state* on page H3-5481.

If an asynchronous exception is also pending after the *Context synchronization event* then the architecture does not define the order in which the debug event and the exception or exceptions are taken.

———— **Note** —————

These rules are based on the rules that apply to taking asynchronous exceptions. See *Asynchronous exception types, routing, masking and priorities* on page D1-1834.

Chapter H4

The Debug Communication Channel and Instruction Transfer Register

This chapter describes communication between a debugger and the implemented debug logic, using the *Debug Communications Channel* (DCC) and the *Instruction Transfer Register* (ITR), and associated control flags. It contains the following sections:

- [Introduction on page H4-5498.](#)
- [DCC and ITR registers on page H4-5499.](#)
- [DCC and ITR access modes on page H4-5502.](#)
- [Flow control of the DCC and ITR registers on page H4-5506.](#)
- [Synchronization of DCC and ITR accesses on page H4-5509.](#)
- [Interrupt-driven use of the DCC on page H4-5514.](#)
- [Pseudocode description of the operation of the DCC and ITR registers on page H4-5515.](#)

———— **Note** —————

Where necessary [Table K11-1 on page K11-6282](#) disambiguates the general register references used in this chapter.

H4.1 Introduction

The *Debug Communications Channel*, DCC, is a channel for passing data between the PE and an external agent, such as a debugger. The DCC provides a communications channel between:

- An external debugger, described as the *debug host*.
- The debug implementation on the PE, described as the *debug target*.

The DCC can be used:

- As a 32-bit full-duplex channel.
- As a 64-bit half-duplex channel.

The DCC is an essential part of Debug state operation and can also be used in Non-debug state.

The *Instruction Transfer Register*, ITR, passes instructions to the PE to execute in Debug state.

The PE includes flow-control mechanisms for both the DCC and ITR.

H4.2 DCC and ITR registers

The DCC comprises *data transfer registers*, the DTRs, and associated flow-control flags. The data transfer registers are DTRRX and DTRTX.

The ITR comprises a single register, [EDITR](#), and associated flow-control flags.

In AArch64 state, software can access the data transfer registers as:

- A receive and transmit pair for 32-bit full duplex operation:
 - The write-only [DBGDTRTX_EL0](#) register to transmit data.
 - The read-only [DBGDTRRX_EL0](#) register to receive data.
- A single 64-bit read/write register, [DBGDTR_EL0](#), for 64-bit half-duplex operation.
- The read/write [OSDTRTX_EL1](#) and [OSDTRRX_EL1](#) registers for save and restore.

In AArch32 state, software can only access the data transfer registers as:

- A receive and transmit pair, for 32-bit full duplex operation:
 - The write-only [DBGDTRTXint](#) register to transmit data.
 - The read-only [DBGDTRRXint](#) register to receive data.
- The read/write [DBGDTRTXext](#) and [DBGDTRRXext](#) registers for save and restore.

The data transfer registers are also accessible by the external debug interface as a pair of 32-bit registers, [DBGDTRRX_EL0](#) and [DBGDTRTX_EL0](#). Both registers are read/write, allowing both 32-bit full-duplex and 64-bit half-duplex operation.

The DCC flow-control flags are [EDSCR](#). {RXfull, TXfull, RXO, TXU}:

- The RXfull and TXfull ready flags are used for flow-control and are visible to software in the debug System registers in [DCCSR](#).
- The RX overrun flag, RXO, and the TX underrun flag, TXU, report flow-control errors.
- The flow-control flags are also accessible by software as simple read/write bits for saving and restoring over a powerdown when the OS Lock is locked in [DSCR](#).
- The flow-control flags are accessible from the external debug interface in [EDSCR](#).

[Figure H4-1 on page H4-5500](#) shows the System register and external debug interface views of the [EDSCR](#) and DTR registers in both AArch64 state and AArch32 state. These figures do not include the save and restore views.

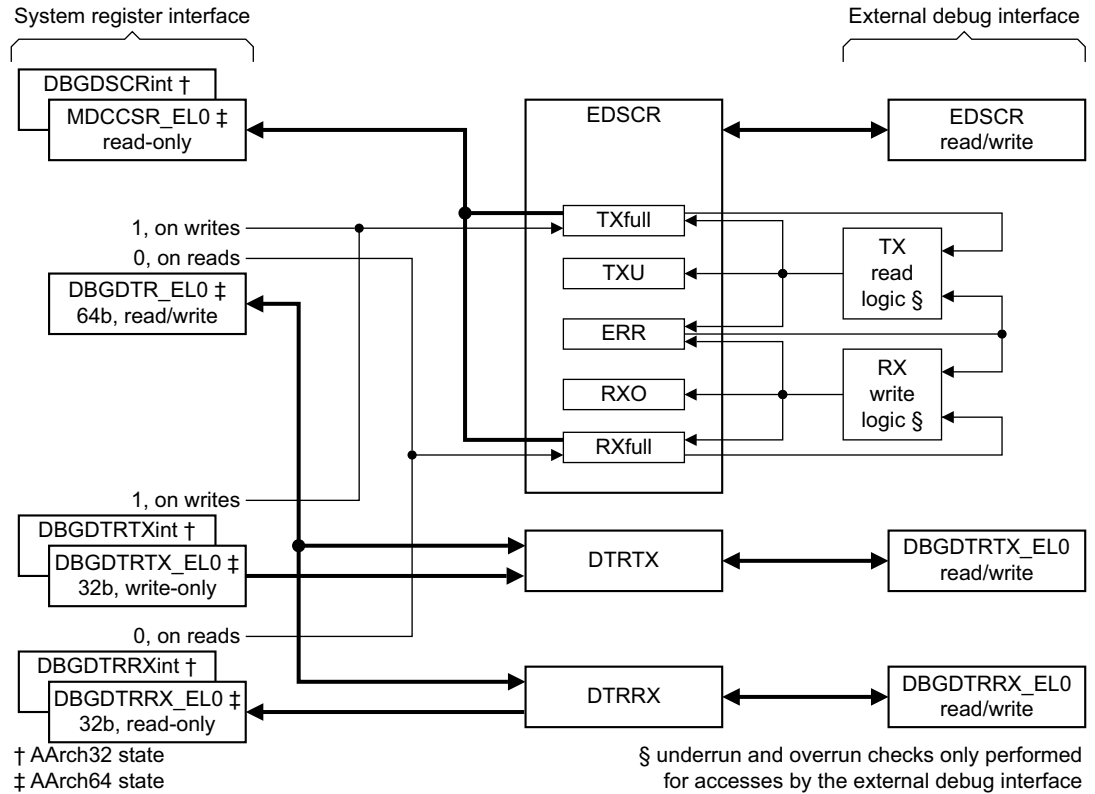

Figure H4-1 System register and external debug interface views of EDSCR and DTR registers, Normal access mode

EDITR and the ITR flow-control flags, EDSCR.{ITE, ITO} are accessible only by the external debug interface:

- The EDITR specifies an instruction to execute in Debug state.
- The ITR empty flag, ITE, is used for flow-control.
- The ITR overrun flag, ITO, reports flow-control errors.

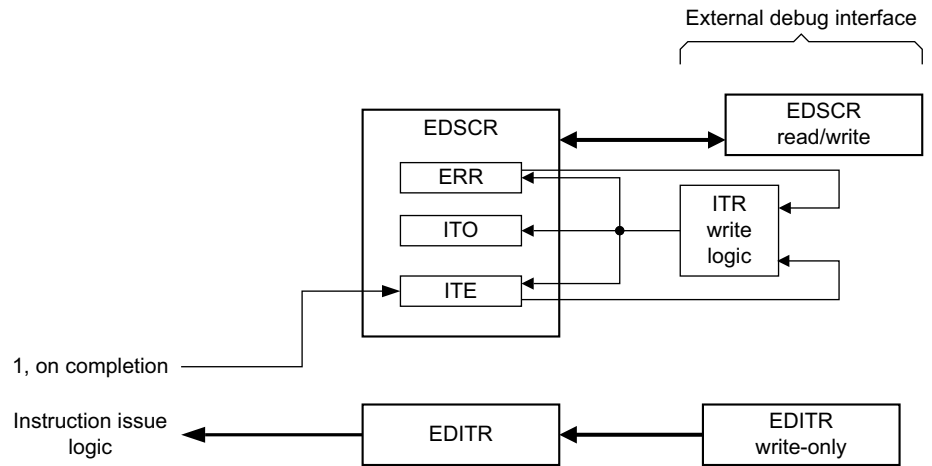

Figure H4-2 External debug interface views of EDSCR and EDITR registers, Normal access mode

The sticky overflow flag, EDSCR.ERR, is used by both the DCC and ITR to report flow-control errors.

To save and restore the DCC registers for an external debugger over powerdown, software uses:

- The MDSCR_EL1, OSDTRTX_EL1, and OSDTRRX_EL1 registers in AArch32 state.

- The `DBGDSCRext`, `DBGDTRTXext`, and `DBGDTRRXext` registers in AArch64 state.

Note

There is no save and restore mechanism for the ITR registers as the ITR is only used in Debug state.

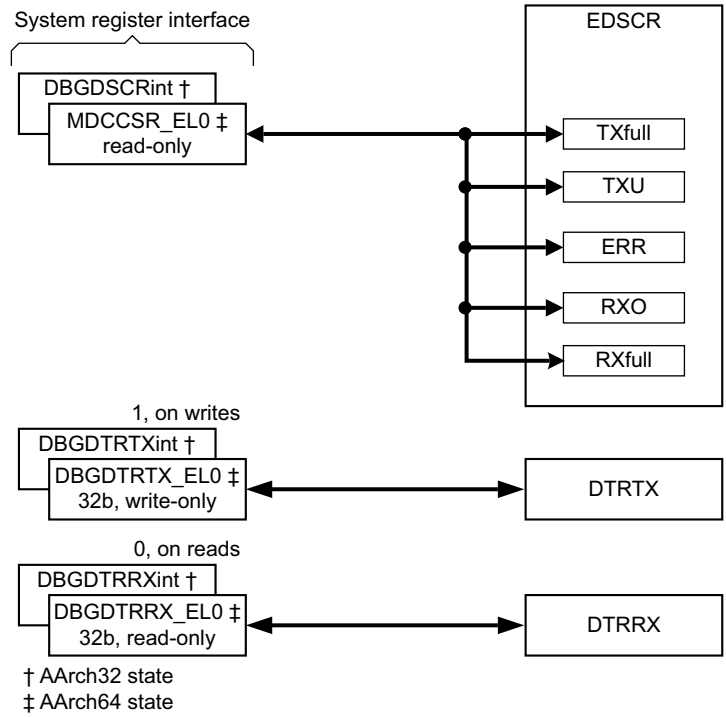

Figure H4-3 System register views of EDSCR and DTR registers for save and restore

H4.3 DCC and ITR access modes

The DCC and ITR support two access modes:

DCC and ITR access mode, links to description	Applies when:
Normal access mode	EDSCR.MA == 0 or the PE is in Non-debug state
Memory access mode on page H4-5503	EDSCR.MA == 1 and the PE is in Debug state

H4.3.1 Normal access mode

The Normal access mode allows use of the DCC as a communications channel between target and host. It also allows the use of the ITR for issuing instructions to the PE in Debug state.

In Normal access mode, if there is no overrun or underrun, the following occurs:

For accesses by software:

- Direct writes to [DBGDTRTX](#) update the value in DTRTX and indirectly write 1 to TXfull.
- Direct reads from [DBGDTRRX](#) return the value in DTRRX and indirectly write 0 to RXfull.
- In AArch64 state, direct writes to [DBGDTR_EL0](#) update both DTRTX and DTRRX, indirectly write 1 to TXfull, and do not change RXfull:
 - DTRTX is set from bits[31:0] of the transfer register.
 - DTRRX is set from bits[63:32] of the transfer register.
- In AArch64 state, direct reads from [DBGDTR_EL0](#) return the concatenation of DTRRX and DTRTX, indirectly write 0 to RXfull, and do not change TXfull:
 - Bits[31:0] of the transfer register are set from DTRRX.
 - Bits[63:32] of the transfer register are set from DTRTX.

Note

For [DBGDTR_EL0](#), the word order is reversed for reads with respect to writes.

Software reads TXfull and RXfull using [DCCSR](#).

For accesses by the external debug interface:

- Writes to [EDITR](#) trigger the instruction to be executed if the PE is in Debug state:
 - If the PE is in AArch64 state, this is an A64 instruction.
 - If the PE is in AArch32 state, this is a T32 instruction. The T32 instruction is a pair of halfwords where the first halfword is taken from the lower 16-bits, and the second halfword is taken from the upper 16-bits.
- Reads of [DBGDTRTX_EL0](#) return the value in DTRTX and indirectly write 0 to TXfull.
- Writes to [DBGDTRTX_EL0](#) update the value in DTRTX and do not change TXfull.
- Reads of [DBGDTRRX_EL0](#) return the value in DTRRX and do not change RXfull.
- Writes to [DBGDTRRX_EL0](#) update the value in DTRRX and indirectly write 1 to RXfull.

TXfull and RXfull are visible to the external debug interface in [EDSCR](#).

The PE detects overrun and underrun by the external debug interface, and records errors in [EDSCR](#). {TXU, RXO, ITO, ERR}. See [Flow control of the DCC and ITR registers on page H4-5506](#).

See also [Synchronization of DCC and ITR accesses on page H4-5509](#).

H4.3.2 Memory access mode

When the PE is in Debug state, *Memory access mode* can be selected to accelerate word-aligned block reads or writes of memory by an external debugger. Memory access mode can only be enabled in Debug state, and no instructions can be issued directly by the debugger when in Memory access mode.

If there is no overrun or underrun when in Memory access mode, an access by the external debug interface results in the following:

- External reads from [DBGDTRTX_EL0](#) cause:
 1. The existing value in DTRTX to be returned. This clears [EDSCR.TXfull](#) to 0.
 2. The equivalent of `LDR W1, [X0], #4`, if in AArch64 state, or `LDR R1, [R0], #4`, if in AArch32 state, to be executed.
 3. The equivalent of the MSR `DBGDTRTX_EL0, X1` instruction, if in AArch64 state, or the MCR `p14, 0, R1, c0, c5, 0` instruction, if in AArch32 state, to be executed.
 4. [EDSCR.{TXfull, ITE}](#) to be set to {1,1}, and X1 or R1 to be set to an UNKNOWN value.
- External writes to [DBGDTRRX_EL0](#) cause:
 1. The value in DTRRX to be updated. This sets [EDSCR.RXfull](#) to 1.
 2. The equivalent of the instruction `MRS X1, DBGDTRRX_EL0`, if in AArch64 state, or `MRC p14, 0, R1, c0, c5, 0` if in AArch32 state, to be executed.
 3. The equivalent of the instruction `STR W1, [X0], #4`, if in AArch64 state, or `STR R1, [R0], #4`, if in AArch32 state, to be executed.
 4. [EDSCR.{RXfull, ITE}](#) to be set to {0,1}, and X1 or R1 to be set to an UNKNOWN value.
- External reads from [DBGDTRRX_EL0](#) return the last value written to DTRRX.
- External writes to [EDITR](#) generate an overrun error.

During these accesses, [EDSCR.{TXfull, RXfull, ITE}](#) are used for flow control.

The architecture does not require precisely when these flags are set or cleared by the sequence of operations outlined in this section. For example, in the case of an external write to [DBGDTRRX_EL0](#), in AArch64 state, `RXfull` might be cleared after step 2, or it might not be cleared until after step 3, as an implementation is free to fuse these steps into a single operation. The architecture does require that the flags are set as at step 4 when the PE is ready to accept a further read or write without causing an overrun error or an underrun error.

The process outlined in this section represents a simple sequential execution model of Memory access mode. An implementation is free to pipeline, buffer, and re-order instructions and transactions, as long as the following remain true:

- Data items are transferred into and out of the DTR in order and without loss of data, other than as a result of an overrun or an underrun.
- Data Aborts occur in order.
- The constraints of the memory type are met.
- In the list describing *External reads from [DBGDTRTX_EL0](#)*:
 - The MSR equivalent operation at step 3 of the sequence reads the value loaded by step 2.
 - If the list is performed in a loop, for all but the first iteration of this list, the value read by step 1 returns the values written by the MSR equivalent operation at the previous iteration of step 3.
- In the list describing *External writes to [DBGDTRRX_EL0](#)*:
 - The MRS equivalent operation at step 2 of the sequence returns the value written at step 1.
 - The STR equivalent at step 3 of the sequence writes the value read at step 2.
- If the PE cannot accept a read or write, as applicable, during the sequence, then the flags are updated to indicate an overrun or underrun

See *Flow control of the DCC and ITR registers* on page H4-5506 for more information on overrun and underrun.

Ordering, access sizes and effect on Exclusives monitors

For the purposes of memory ordering, access sizes, and effect on the Exclusives monitor, accesses in Memory access mode are consistent with Load/Store word instructions executed by the PE.

The simple sequential access model of Memory-access mode, as stated in *Memory access mode* on page H4-5503, must also be ordered with respect to instructions executed as a result of explicit writes to **EDITR** in Normal mode both before and after accesses to the DTR registers in Memory-access mode.

Data Aborts in Memory access mode

If a memory access generates a Data Abort, then:

- The Data Abort exception is taken. See *Exceptions in Debug state* on page H2-5465:
 - This means **EDSCR.ERR** is set to 1, see *Cumulative error flag* on page H4-5508.
 - If the Data Abort occurs on stage 2 of an address translation, then the values returned in the ISV field and in bits[23:14] of the ISS are UNKNOWN.
If this Data Abort is taken to EL2 using AArch64, the ISS is returned by **ESR_EL2**. *ISS encoding for an exception from a Data Abort* on page D7-2277 describes the usual encoding of this ISS.
If EL2 is using AArch32 and this Data Abort is taken to Hyp mode, the ISS is returned by **HSR**. *ISS encoding for an exception from a Data Abort* on page G6-4960 describes the usual encoding of this ISS.
- Register R0 retains the address that generated the abort.
- Register R1 is set to an UNKNOWN value.
- **EDSCR.TXfull**, for a load, or **EDSCR.RXfull**, for a store, is set to an UNKNOWN value.
- **DTRTX**, for a load, or **DTRRX**, for a store, is set to an UNKNOWN value.
- **EDSCR.ITE** is set to 1.

Illegal Execution state exception

If **PSTATE.IL** is set to 1 when **EDSCR.MA** == 1, then on an external write access to **DBGDTRRX_ELO** or an external read from **DBGDTRTX_ELO**, it is CONSTRAINED UNPREDICTABLE whether the PE:

- Takes an Illegal Execution state exception without performing any operations. In this case:
 - **EDSCR.ERR** is set to 1, see *Cumulative error flag* on page H4-5508.
 - Register R0 is unchanged.
 - Register R1 is set to an UNKNOWN value.
 - **EDSCR.TXfull** or **EDSCR.RXfull**, as applicable, is set to an UNKNOWN value.
 - **DTRTX** or **DTRRX**, as applicable, is set to an UNKNOWN value.
 - **EDSCR.ITE** is set to 1.See also *Exceptions in Debug state* on page H2-5465.
- Ignores **PSTATE.IL**.

———— Note —————

The typical usage model for Memory access mode involves executing instructions in Normal access mode to set up X0 before setting **EDSCR.MA** to 1. These instructions generate an Illegal state exception if **PSTATE.IL** is set to 1.

Alignment constraints

If the address in R0 is not aligned to a multiple of four, the behavior is as follows:

- For each external DTR access a CONSTRAINED UNPREDICTABLE choice of:
 1. The PE makes an unaligned memory access to R0. If alignment checking is enabled for the memory access, this generates an Alignment fault.
 2. The PE makes a memory access to $\text{Align}(X[0], 4)$ in AArch64 state, or $\text{Align}(R[0], 4)$ in AArch32 state.
 3. The PE generates an Alignment fault, regardless of whether alignment checking is enabled.
 4. The PE does nothing.
- Following each memory access, if there is no Data Abort, R0 is updated with an UNKNOWN value.
- For external writes to `DBGDTRRX_ELO`, if the PE writes to memory, an UNKNOWN value is written.
- For external reads of `DBGDTRTX_ELO` an UNKNOWN value is returned.
- The RXfull and TXfull flags are left in an UNKNOWN state, meaning that a `DBGDTRTX_ELO` read can trigger a TX underrun, and a `DBGDTRTX_ELO` write can trigger an RX overrun.

H4.3.3 Memory-mapped accesses to the DCC and ITR

Writes to the flags in `EDSCR` by external debug interface accesses to the DCC and the ITR registers are indirect writes, because they are a side-effect of the access. The indirect write might not occur for a memory-mapped access to the external debug interface. For more information, see *Register access permissions for memory-mapped accesses* on page H8-5558.

H4.4 Flow control of the DCC and ITR registers

This sub-section describes the flow-control of the DCC and ITR registers:

- [Ready flags](#).
- [Buffering writes to EDITR](#).
- [Overrun and underrun flags on page H4-5507](#).
- [Cumulative error flag on page H4-5508](#).

H4.4.1 Ready flags

In Normal access mode:

- For the DTR registers there are two ready flags:
 - `EDSCR.RXfull == 1` indicates that `DBGDTRRX_EL0` contains a valid value that has been written by the external debugger and not yet read by software running on the target.
 - `EDSCR.TXfull == 1` indicates that `DBGDTRTX_EL0` contains a valid value that has been written by software running on the target and not yet read by an external debugger.
- For the ITR register there is a single ready flag:
 - `EDSCR.ITE == 1` indicates that the PE is ready to accept an instruction to the ITR.

———— **Note** —————

The architecture permits a PE to continue to accept and buffer instructions when previous instructions have not completed their architecturally defined behavior, as long as those instructions are discarded if `EDSCR.ERR` is set, either by an underrun or overrun or by any of the other error conditions described in this architecture, such as an instruction generating an abort.

In Memory access mode:

- `EDSCR.{RXfull, ITE} == {0,1}` indicates that `DBGDTRRX_EL0` is empty and the PE is ready to accept a word external write to `DBGDTRRX_EL0`.
- `EDSCR.{TXfull, ITE} == {1,1}` indicates that `DBGDTRTX_EL0` is full and the PE is ready to accept a word external read from `DBGDTRTX_EL0`.

All other values indicate that the PE is not ready, and result in a DTR overrun or underrun error, an ITR overrun error, or both, as defined in [Overrun and underrun flags on page H4-5507](#).

`EDSCR.{ITE, RXfull, TXfull}` shows the status of the ITR and DCC registers. It ignores the question of whether a read or write cannot be accepted because, for example, `EDSCR.ERR` is set or the OPTIONAL Software Lock is locked for memory-mapped accesses (`EDLSR.SLK == 1`).

H4.4.2 Buffering writes to EDITR

The architecture permits a processor to continue to accept and buffer instructions when previous instructions have not completed their architecturally defined behavior, provided that:

- Those instructions are discarded if `EDSCR.ERR` is set to 1, either by an underrun or an overrun, or by any other error conditions described in this architecture, such as an instruction generating an abort.
- The PE maintains the simple sequential execution model with the order of instructions determined by the order in which the PE accepts the EDITR writes. In particular, the buffered instructions must be executed in the Execution state consistent with a simple sequential execution of the instructions, even if one of the previous instructions is a state changing operation, such as DCPS or DRPS.

H4.4.3 Overrun and underrun flags

Each of the ready flags has a corresponding overrun or a corresponding underrun flag. These are sticky status flags that are set if the register is accessed using the external debug interface when the corresponding ready flag is not in the ready state.

If the PE is in Debug state and Memory access mode, the corresponding error flag is also set if the PE is not ready to accept an operation because a previous load or store is still in progress. The sticky status flag remains set until cleared by writing 1 to [EDSCR.CSE](#).

———— **Note** ————

The architecture permits a PE to continue to accept and buffer data to write to memory in Memory access mode.

[Table H4-1](#) shows DCC and ITR ready flags and the overrun and underrun flags associated with them.

Table H4-1 DCC and ITR ready flags and the associated overrun/underrun flags

External debug interface access	Overrun/Underrun condition	EDSCR flag
Write DBGDTRRX_EL0	$\text{EDSCR.RXfull} == '1' \ \ (\text{Halted}() \ \&\& \ \text{EDSCR.MA} == '1' \ \&\& \ \text{EDSCR.ITE} == '0')$	RXO
Read DBGDTRTX_EL0	$\text{EDSCR.TXfull} == '0' \ \ (\text{Halted}() \ \&\& \ \text{EDSCR.MA} == '1' \ \&\& \ \text{EDSCR.ITE} == '0')$	TXU
Write EDITR	$\text{Halted}() \ \&\& \ (\text{EDSCR.ITE} == '0' \ \ \text{EDSCR.MA} == '1')$	ITO

When an overrun or underrun flag is set to 1, the cumulative error flag, [EDSCR.ERR](#), described in [Cumulative error flag on page H4-5508](#), is also set to 1.

In the event of an external write to [DBGDTRRX_EL0](#) or [EDITR](#) generating an overrun, or an external read from [DBGDTRTX_EL0](#) generating an underrun:

- For a write, the written value is ignored.
- For a read, an UNKNOWN value is returned.
- [EDSCR.TXfull](#), [EDSCR.RXfull](#) or [EDSCR.ITE](#), as applicable, are not updated.

There is no overrun or underrun detection on external reads of [DBGDTRRX_EL0](#) or external writes of [DBGDTRTX_EL0](#).

There is no overrun or underrun detection of direct reads and direct writes of the DTR System registers by software:

- If $\text{RXfull} == 0$, a direct read of [DBGDTRRX](#) or [DBGDTR_EL0](#) returns UNKNOWN.
- If $\text{TXfull} == 1$, a direct write of:
 - [DBGDTRTX](#) sets DTRTX to UNKNOWN.
 - [DBGDTR_EL0](#) sets DTRRX and DTRTX to UNKNOWN.

See [DCC accesses in Non-debug state on page H4-5510](#) for more information.

Accessing 64-bit data

In AArch64 state, a software access to the [DBGDTR_EL0](#) register and an external debugger access to both [DBGDTRRX_EL0](#) and [DBGDTRTX_EL0](#) can perform a 64-bit half-duplex operation.

However, there is only overrun and underrun detection on one of the external debug registers. That is:

- If software directly writes a 64-bit value to [DBGDTR_EL0](#), only TXfull is set to 1, meaning:
 - A subsequent external write to [DBGDTRRX_EL0](#) would not be detected as an overrun.
 - If the external debugger reads [DBGDTRTX_EL0](#) first, software might observe [MDCCSR_EL0.TXfull](#) == 0 and send a second value before the external debugger reads [DBGDTRRX_EL0](#), leading to an undetected overrun.

- On external writes to both [DBGDTRRX_EL0](#) and [DBGDTRTX_EL0](#) only RXfull is set to 1, meaning:
 - A subsequent direct write of [DBGDTRTX_EL0](#) would not be detected as an overrun.
 - If the external debugger writes to [DBGDTRRX_EL0](#) first, software might observe [MDCCSR_EL0.RXfull](#) == 1 and read a full 64-bit value, before the external debugger writes to [DBGDTRTX_EL0](#), leading to an undetected underrun.

To avoid this, debuggers need to be aware of the data size used by software for transfers and ensure that 64-bit data is read or written in the correct order. If the PE is in Non-debug state, this order is as follows:

- The external debugger must check [EDSCR](#).{RXfull, TXfull} before each transfer.
- To receive a 64-bit value from the target, the external debugger must read [DBGDTRRX_EL0](#) before reading [DBGDTRTX_EL0](#).
- To send a 64-bit value to the target, the external debugger must write to [DBGDTRTX_EL0](#) before writing [DBGDTRRX_EL0](#).

Because three accesses are required to transfer 64 bits of data, 64-bit transfers are not recommended for regular communication between host and target. The use of overrun and underrun detection means that only one access is required for 32 bits of data when using 32-bit transfers.

In Debug state, the debugger controls the instructions executed by the PE, so these limitations do not apply. 64-bit transfers provide a means to transfer a 64-bit general register between the host and the target in Debug state.

H4.4.4 Cumulative error flag

The cumulative error flag, [EDSCR](#).ERR, is set to 1:

- On taking an exception from Debug state.
- On any signaled overrun or underrun in the DCC or ITR.

When [EDSCR](#).ERR == 1:

- External reads of [DBGDTRTX_EL0](#) do not have any side-effects.
- External writes to [DBGDTRRX_EL0](#) are ignored.
- External writes to [EDITR](#) are ignored.
- No further instructions can be issued in Debug state. This includes any instructions previously accepted as external writes to [EDITR](#) that occur in program order after the instruction or access that caused the error.

This allows a debugger to stream data, or, in Debug state, instructions, to the target without having to:

- Check [EDSCR](#).{RXfull, TXfull, ITE} before each access.
- Check [EDSCR](#).{ITO, RXO, TXU} following each access, for overrun or underrun.
- Check [PSTATE](#) or other syndrome registers, or both, for an exception following each instruction executed in Debug state that might generate a synchronous exception.

The cumulative error flag remains set until cleared by writing 1 to [EDRCR](#).CSE. See [EDRCR](#), *External Debug Reserve Control Register* on page H9-5660.

For overruns and underruns, [EDSCR](#).{ITO, RXO, TXU} record the error type.

Pseudocode description of clearing the error flag

The [ClearStickyErrors\(\)](#) pseudocode function is described in [Chapter J1 ARMv8 Pseudocode](#).

H4.5 Synchronization of DCC and ITR accesses

In addition to the standard synchronization requirements for register accesses, the following subsections describe additional requirements that apply for the DCC and ITR registers:

- [Summary of System register accesses to the DCC.](#)
- [DCC accesses in Non-debug state on page H4-5510.](#)

In these sections, accesses by the external debug interface are referred to as external reads and external writes. Accesses to System registers are referred to as direct reads, direct writes, indirect reads, and indirect writes.

———— **Note** —————

In [Synchronization requirements for AArch64 System registers on page D7-2191](#) external reads and external writes are described as forms of indirect access. This whole section uses more explicit terminology.

The DTR registers and the DCC flags, TXfull and RXfull, form a communication channel, with one end operating asynchronously to the other. Implementations must respect the ordering of accesses to these registers in order to maintain the correct behavior of the channel.

External reads of, and external writes to [DBGDTRRX_EL0](#) and [DBGDTRTX_EL0](#) are asynchronous to direct reads of, and direct writes to, [DBGDTRRX](#), [DBGDTRTX](#), and in AArch64 state [DBGDTR_EL0](#), made by software using System register access instructions. The direct reads and direct writes indirectly write to the DCC flags. The external reads and external writes indirectly read the DCC flags to check for underrun and overrun.

Throughout this section:

- DCC flags** Means any or all of the following:
- The [EDSCR](#).{RXfull.TXfull} ready flags.
 - The [EDSCR](#).RXO overrun flag.
 - The [EDSCR](#).TXU underrun flag.
 - The [EDSCR](#).ERR cumulative error flag.
- ITR flags** Means any or all of the following:
- The [EDSCR](#).ITE ready flag.
 - The [EDSCR](#).ITO overrun flag.
 - The [EDSCR](#).ERR cumulative error flag.

H4.5.1 Summary of System register accesses to the DCC

System register accesses to the DTR registers are direct reads and writes of those registers, as shown in [Table H4-2 on page H4-5510](#). Several of these instructions access the same registers using different encodings.

With the exception of the read and write bits, [DBGDTRRX](#) and [DBGDTRTX](#) are the same encoding, with exception of the read/write bits, but use different registers. The ARMv8 architecture governs the order of these instructions, as described in [Synchronization requirements for AArch64 System registers on page D7-2191](#). For more details, see the description of the individual register in the relevant chapter, [Chapter D7 AArch64 System Register Descriptions](#) or [Chapter G6 AArch32 System Register Descriptions](#).

Table H4-2 shows a summary of System register accesses to the DCC.

Table H4-2 Summary of System register accesses to the DCC

Operation	OS Lock	AArch64 (MRS/MSR)	AArch32 (MRC/MCR)	Description
Read	-	DBGDTRRX_EL0	DBGDTRRXint	Direct read of DTRRX Indirect write to the DCC flags
Write	-	DBGDTRTX_EL0	DBGDTRTXint	Direct read of DTRTX Indirect write to the DCC flags
Read/write	-	DBGDTR_EL0	-	Direct read/write of both DTRRX and DTRTX Indirect write to the DCC flags
Read	-	MDCCSR_EL0	DBGDSCRint	Direct read of the DCC flags
Read/write	-	OSDTRRX_EL1	DBGDTRRXext	Direct read/write of DTRRX
Read/write	-	OSDTRTX_EL1	DBGDTRTXext	Direct read/write of DTRTX
Read	Unlocked	MDSCR_EL1	DBGDSCRext	Direct read of DCC flags
Read/write	Locked	MDSCR_EL1	DBGDSCRext	Direct read/write of DCC flags

H4.5.2 DCC accesses in Non-debug state

In Non-debug state DCC accesses are as described in *Normal access mode* on page H4-5502:

- If a direct read of [DCCSR](#) returns `RXfull == 1`, then a following direct read of [DBGDTRRX](#), or in AArch64 state of [DBGDTR_EL0](#), returns valid data and indirectly writes 0 to [DCCSR.RXfull](#) as a side-effect.
- If a direct read of [DCCSR](#) returns `TXfull == 0`, then a following direct write to [DBGDTRTX](#), or in AArch64 state to [DBGDTR_EL0](#), writes the intended value, and indirectly writes 1 to [DCCSR.TXfull](#) as a side-effect.

No *Context synchronization event* is required between these two instructions. Overrun and underrun detection prevents intervening external reads and external writes affecting the outcome of the second instruction.

The indirect write to the [DCC flags](#) as part of the DTR access instruction is made atomically with the DTR access.

Because a direct read of [DBGDTRRX](#) is an indirect write to [DCCSR.RXfull](#), it must occur in program order with respect to the direct read of [DCCSR](#), meaning it must not return a speculative value for DTRTX that predates the `RXfull` flag returned by the read of [DCCSR](#). The direct write to [DBGDTRTX](#) must not be executed speculatively.

Direct reads of [DBGDTRRX](#), or in AArch64 state [DBGDTR_EL0](#), and [DCCSR](#), must occur in program order with respect to other direct reads of the same register using the same encoding.

The following accesses have an implied order within the atomic access:

- In the simple sequential execution of the program the indirect write of the [DCC flags](#) occurs immediately after the direct DTR access.

———— **Note** —————

For an access to [DBGDTR_EL0](#), this means the indirect write happens after both [DBGDTRRX_EL0](#) and [DBGDTRTX_EL0](#) have been accessed.

- In the simple sequential execution model, for an external read of `DBGDTRTX_EL0` or an external write of `DBGDTRRX_EL0`:
 - The check of the **DCC flags** for overrun or underrun occurs immediately before the access.
 - If there is no underrun or overrun, the update of the **DCC flags** occurs immediately after the access.
 - If there is underrun or overrun, the update of the DCC underrun or overrun flags occurs immediately after the access.

All observers must observe the same order for accesses.

———— **Note** —————

These requirements do not create order where order does not otherwise exist. It applies only for ordered accesses.

Without explicit synchronization following external writes and external reads:

- The value written by the external write to `DBGDTRRX_EL0` that does not overrun, must be observable to direct reads of `DBGDTRRX` and `DBGDTR_EL0` in finite time.
- The **DCC flags** that are updated as a side-effect of the external write or external read must be observable:
 - To subsequent external reads of `EDSCR`.
 - To subsequent external reads of `DBGDTRRX_EL0` when checking for underrun.
 - To subsequent external writes to `DBGDTRTX_EL0` when checking for overrun.
 - To direct reads of `DCCSR` in finite time.

However, explicit synchronization is required to guarantee that a direct read of `DCCSR` returns up-to-date **DCC flags**. This means that if a signal is received from another agent that indicates that `DCCSR` must be read, an ISB is required to ensure that the direct read of `DCCSR` occurs after the signal has been received. This also synchronizes the value in `DBGDTRRX`, if applicable. However, if that signal is an interrupt exception triggered by `COMMIRQ`, `COMMTX`, or `COMMRX`, the exception entry is sufficient synchronization. See *Synchronization of DCC interrupt request signals* on page H4-5513.

Explicit synchronization is required following a direct read or direct write:

- To ensure that a value directly written to `DBGDTRTX` is observable to external reads of `DBGDTRTX_EL0`.
- To ensure that a value directly written to `DBGDTR_EL0` is observable to external reads of `DBGDTRTX_EL0` and `DBGDTRRX_EL0`.
- To guarantee that the indirect writes to the **DCC flags** that were a side-effect of the direct read or direct write have occurred, and therefore that the updated values are:
 - Observable to external reads of `EDSCR`.
 - Observable to external reads of `DBGDTRRX_EL0` when checking for underrun.
 - Observable to external writes of `DBGDTRTX_EL0` when checking for overrun.
 - Returned by a following direct read of `DCCSR`.

See also *Memory-mapped accesses to the DCC and ITR* on page H4-5505 and *Synchronization of changes to the external debug registers* on page H8-5554.

———— **Note** —————

These ordering rules mean that software:

- Must not read `DBGDTRRX` without first checking `DCCSR.RXfull` or if the previously-read value of `DCCSR.RXfull` is 0.
It is not sufficient to read both registers and then later decide whether to discard the read value, as there might be an intervening write from the external debug interface.

- Must not write **DBGDTRTX** without first checking **DCCSR.TXfull** or if the previously-read value of **DCCSR.TXfull** is 1.
The write to **DBGDTRTX** overwrites the value in **DTRTX**, and the external debugger might or might not have read this value.
 - Must ensure there is an explicit *Context synchronization event* following a DTR access, even if not immediately returning to read **DCCSR** again. This synchronization operation can be an exception return.
-

Derived requirements

The rules for DCC accesses in Non-debug state are as follows:

- Following a direct read of **DBGDTRRX** when **RXfull** is 1:
 - If an external write to **DBGDTRRX** checks the **RXfull** flag for overrun and observes that the value of **RXfull** is 0, the value returned by the previous direct read must not be affected by the external write.
 - If an external read of **EDSCR** returns a **RXfull** value of 0, then the value returned by the previous direct read must not be affected by a following external write to **DBGDTRRX**, and the following external write does not overrun.
- Following a direct read of **DBGDTR_EL0**, when **RXfull** is 1:
 - If an external write to **DBGDTRRX** checks the **RXfull** flag for overrun and observes that the value of **RXfull** is 0, the value returned by the previous direct read must not be affected by the external write nor by a following direct write to **DBGDTRTX**.
 - If an external read of **EDSCR** returns a **RXfull** value of 0, then the value returned by the previous direct read must not be affected by subsequent external writes to **DBGDTRRX** and **DBGDTRTX** in any order, and the following external write of **DBGDTRRX** will not overrun.
- Following a direct write to **DBGDTRTX**, when **TXfull** is 0:
 - If an external read of **DBGDTRTX** checks the **TXfull** flag for underrun and observes that the value of **TXfull** is 1, the value returned by the external read must be the value written by the previous direct write.
 - If an external read of **EDSCR** returns a **TXfull** value of 1, then the value returned by a following external read of **DBGDTRRX** must be the value written by the previous direct read, and the subsequent external read will not underrun.
- Following a direct write to **DBGDTR_EL0**, when **TXfull** is 0:
 - If an external read of **DBGDTRTX** checks the **TXfull** flag for underrun and observes that the value of **TXfull** is 1, the values returned by the external read and by a subsequent external read of **DBGDTRRX** must be the value written by the previous direct write.
 - If an external read of **EDSCR** returns a **TXfull** value of 1, then the value returned by subsequent external reads of **DBGDTRRX** and **DBGDTRTX**, in any order, must be the value written by the previous direct read, and the subsequent external read of **DBGDTRTX** does not underrun.
- Following an external read of **DBGDTRTX** that does not underrun, if a direct read of **DCCSR** returns a **TXfull** value of 0, then the value returned by the external read must not be affected by a following direct write to **DBGDTRTX**.
- Following a first external read **DBGDTRRX** and a following second external read of **DBGDTRTX** that does not underrun, if a direct read of **DCCSR** returns a **TXfull** value of 0, then the values returned by the external reads must not be affected by a following direct write to **DBGDTR_EL0**.
- Following an external write to **DBGDTRRX** that does not overrun, if a direct read of **DCCSR** returns an **RXfull** value of 1, then the value returned by a following direct read of **DBGDTRRX** or **DBGDTR_EL0** must be the value written by the previous external write.

- Following a first external write to **DBGDTRTX** and a following second external write to **DBGDTRRX** that does not overrun, if a direct read of **DCCSR** returns an **RXfull** value of 1, then the value returned by a subsequent direct read of **DBGDTR_EL0** must return the values written by the previous external writes.

H4.5.3 Synchronization of DCC interrupt request signals

Following an external read or external write access to the DTR registers, the interrupt request signals, **COMMIRQ**, **COMMTX**, and **COMMRX**, must be updated in finite time without explicit synchronization.

The updated values must be observable to a direct read of **DCCSR** or **DBGDTRRX**, or a direct write of **DBGDTRTX** executed after taking an interrupt exception generated by the interrupt request. The updated values must also be observable to a direct write of **DBGDTRTX** executed after taking an interrupt exception generated by the interrupt request.

Following a direct read of **DBGDTRRX** or a direct write to **DBGDTRRX**, software must execute a *Context synchronization event* to guarantee the interrupt request signals have been updated in finite time. This synchronization operation can be an exception return.

H4.5.4 DCC and ITR access in Debug state

In Debug state, stricter observability rules apply for instructions issued through the ITR, to maintain communication between a debugger and the PE, without requiring excessive explicit synchronization.

In Normal access mode, without explicit synchronization:

- A direct read or direct write of the DTR registers by an instruction written to **EDITR** must be observable to an external write or an external read in finite time:
 - A direct read of **DBGDTRRX** must be observable to an external write of **DBGDTRRX_EL0**.
 - A direct read of **DBGDTR_EL0** must be observable to an external write of **DBGDTRRX_EL0** and **DBGDTRTX_EL0**.
 - A direct write of **DBGDTRTX** must be observable to an external read of **DBGDTRTX_EL0**.
 - A direct write of **DBGDTR_EL0** must be observable to an external read of **DBGDTRRX_EL0** and **DBGDTRTX_EL0**.

This includes the indirect write to the **DCC flags** that occurs atomically with the access as described in *DCC accesses in Non-debug state* on page H4-5510.

The subsequent external write or external read must observe either the old or the new values of both the DTR contents and **DCC flags**. If the old values are observed, this typically results in overrun or underrun, assuming the old values of the **DCC flags** indicate an overrun or underrun condition, as would normally be the case.

This means the debugger can observe the direct read or direct write without explicit synchronization and without explicitly testing the **DCC flags** in **EDSCR**, because it can rely on overrun and underrun tests.

- External reads of **DBGDTRTX_EL0** that do not underrun and external writes to **DBGDTRRX_EL0** that do not overrun must be observable to an instruction subsequently written to **EDITR** on completion of the first external access. This includes the indirect write to the **DCC flags**.

This means that without explicit synchronization and without the need to first check the **DCC flags** in **DCCSR**:

- If the instruction is a direct read of **DBGDTRRX**, it observes the external write.
- If the instruction is a direct write of **DBGDTRTX**, it observes the external read.
- Writes to **EDITR** that do not overrun commit an instruction for execution immediately. The instruction must complete execution in finite time without requiring any further operation by the debugger.
- After an external write to the **EDITR**, the **ITR flags** that are updated as a side effect of that write must be observable by:
 - An external read of the **EDSCR** that follows the external write to the **EDITR**.
 - When checking for overrun, another external write to the **EDITR** that follows the original external write to the **EDITR**.

In Memory access mode, these requirements shift to the instructions implicitly executed by external reads and external writes of the DTR registers, as described in *Memory access mode* on page H4-5503.

H4.6 Interrupt-driven use of the DCC

ARM recommends implementations provide a level-sensitive DCC interrupt request through the IMPLEMENTATION DEFINED interrupt controller as a private peripheral interrupt for the originating PE.

———— **Note** —————

- In addition to connection to the interrupt controller ARM also recommends **COMMIRQ**, **COMMTX**, and **COMMRX** signals that might be implemented for use by any legacy system peripherals.
- GICv3 reserves a private peripheral interrupt number for the **COMMIRQ** interrupt.

The **DCCINT** register provides a first level of interrupt masking within the PE, meaning only a single interrupt source, **COMMIRQ**, is needed at the interrupt controller.

See also [Synchronization of DCC interrupt request signals on page H4-5513](#).

H4.7 Pseudocode description of the operation of the DCC and ITR registers

The basic operation of the DCC and ITR registers is shown by the following pseudocode functions. These functions do not cover the behavior when `OSLSR.OSLK == 1`, meaning that the OS lock is locked:

- `DBGDTR_EL0[]`.
- `DBGDTRRX_EL0[]`.
- `DBGDTRTX_EL0[]`.
- `EDITR[]`.
- `CheckForDCCInterrupts()`.

For the definition of the DTR Registers, see [shared/debug/dccanditr/DTR](#) on page J1-6013.

Chapter H5

The Embedded Cross-Trigger Interface

This chapter describes the embedded cross-trigger interface. It contains the following sections:

- *About the Embedded Cross-Trigger (ECT) on page H5-5518.*
- *Basic operation on the ECT on page H5-5520.*
- *Cross-triggers on a PE in an ARMv8 implementation on page H5-5524.*
- *Description and allocation of CTI triggers on page H5-5525.*
- *CTI registers programmers' model on page H5-5529.*
- *Examples on page H5-5530.*

H5.1 About the Embedded Cross-Trigger (ECT)

The *Embedded Cross-Trigger*, ECT, allows a debugger to:

- Send trigger events to a PE. For example, this might be done to halt the PE.
- Send a trigger event to one or more PEs when a trigger event occurs on another PE. For example, this might be done to halt all PEs when one individual PE halts.

Figure H5-1 shows the logical structure of an ECT.

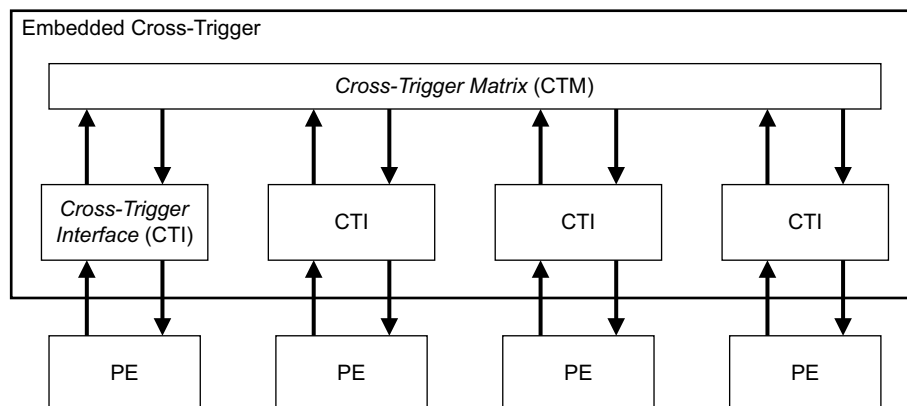

Figure H5-1 Structure of an embedded cross-trigger

The ECT can deliver many types of trigger events, which are described in the following sections:

- [Debug request trigger event on page H5-5526.](#)
- [Restart request trigger event on page H5-5526.](#)
- [Cross-halt trigger event on page H5-5526.](#)
- [Performance Monitors overflow trigger event on page H5-5527.](#)
- [Generic trace external input trigger events on page H5-5527.](#)
- [Generic trace external output trigger events on page H5-5527.](#)
- [Generic CTI interrupt trigger event on page H5-5527.](#)

An ARMv8-A implementation must:

- Include a cross-trigger interface, CTI.
- Implement at least the input and output triggers defined in this architecture.

See [Cross-triggers on a PE in an ARMv8 implementation on page H5-5524.](#)

In addition, ARM recommends that the cross-trigger includes:

- The ability to route trigger events between Trace macrocells:
These typically have advanced event triggering logic.
- An output trigger to the interrupt controller.

———— Note ————

The ECT and CTI must only signal trigger events for external debugging. They must not route software events, such as interrupts. For example, the Performance Monitors overflow input trigger is provided to allow entry to Debug state on a counter overflow, and the output trigger to the interrupt controller is provided to generally allow events from the external debug sub-system to be routed to a software agent. However, the combination of the two must not be used as a mechanism to route Performance Monitors overflows to an interrupt controller.

H5.1.1 Implementation with a CoreSight CTI

For details of the recommended connections in an ARMv8-A implementation, see [Appendix K2 Recommended External Debug Interface](#). See also *CoreSight™ SoC Technical Reference Manual*.

H5.2 Basic operation on the ECT

The ECT comprises a Cross-Trigger Matrix, CTM, and one Cross-Trigger Interface, CTI, for each PE. The CTM passes events between the CTI blocks over channels. The CTM can have a maximum of 32 channels.

The main interfaces of the cross-trigger interface, CTI, are:

- The input triggers:
 - These are trigger event inputs from the PE to the CTI.
- The output triggers:
 - These are trigger event outputs from the CTI to the PE.
- The input channels:
 - These are channel event inputs from the cross-trigger matrix, CTM, to the CTI.
- The output channels:
 - These are channel event outputs from the CTI to the CTM.

Each CTI block has:

- Up to 32 input triggers that come from the PE:
 - The input triggers are numbered 0-31.
- Up to 32 output triggers that go to the PE:
 - The output triggers are numbered 0-31.

[Figure H5-2 on page H5-5521](#) shows the logical internal structure of a CTI.

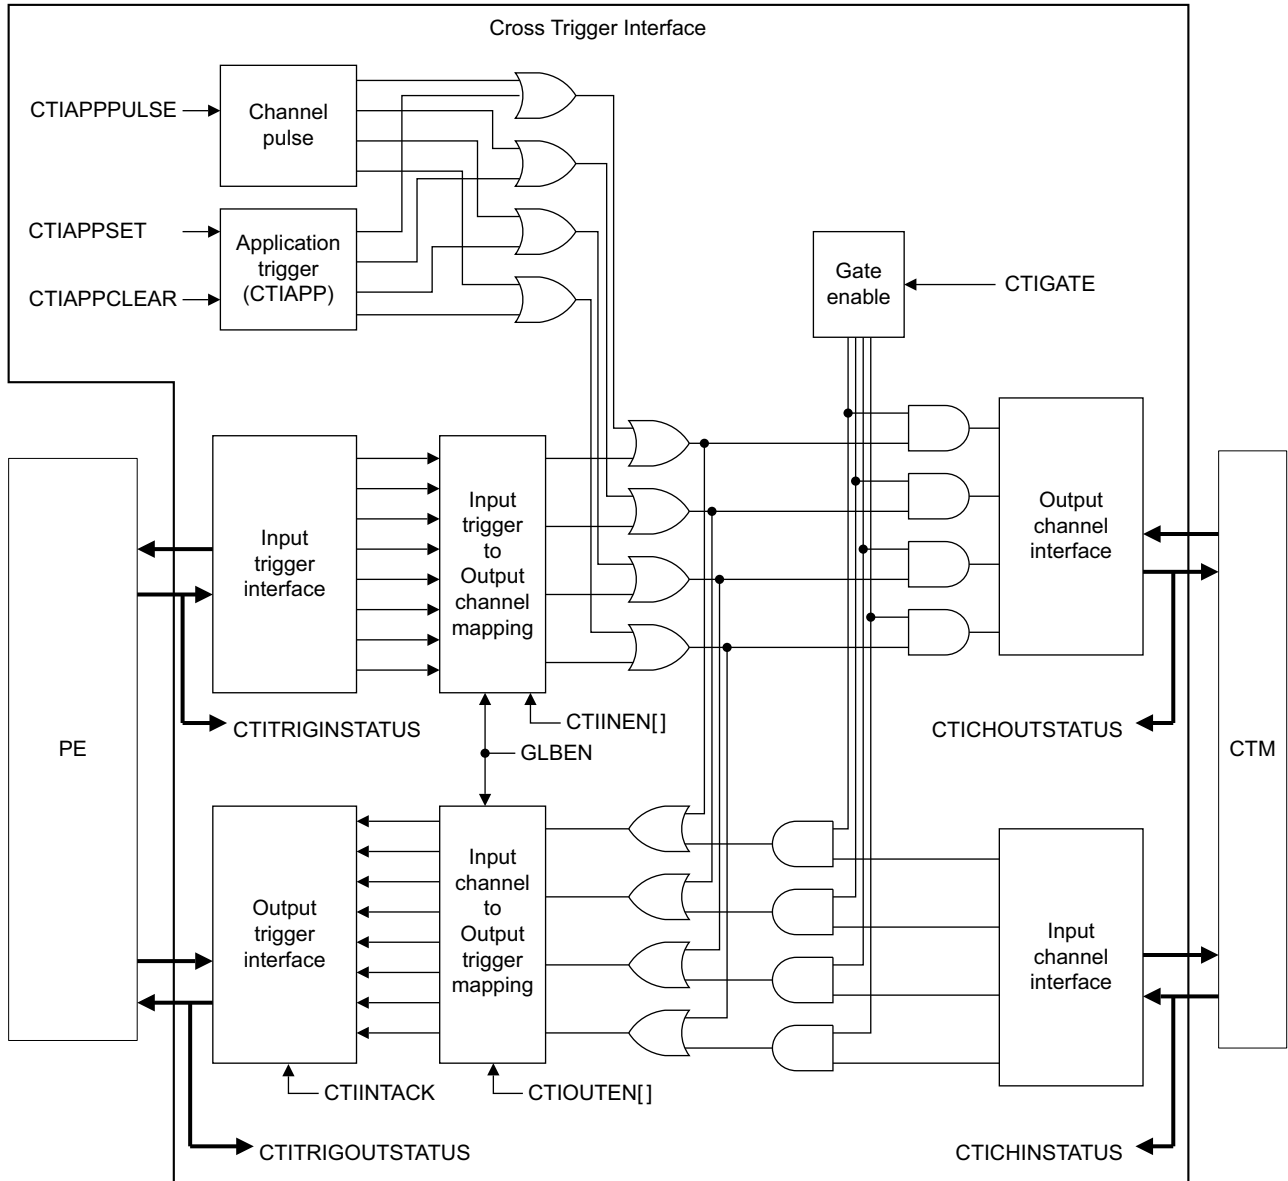

Figure H5-2 Structure of a cross-trigger interface

Note

- The number of triggers is IMPLEMENTATION DEFINED. Figure H5-2 shows eight input and eight output triggers.
- The number of channels is IMPLEMENTATION DEFINED. Figure H5-2 shows four channels.
- In Figure H5-2 the input channel gate function is a CTIv2 feature.

When the CTI receives an input trigger event, this generates channel events on one or more internal channels, according to the *mapping function* defined by the *Input trigger→output channel mapping registers*, CTIINEN<n>.

The CTI also contains an *application trigger* and *channel pulse* to allow a debugger to create channel events directly on internal channels by writing to the CTI control registers.

Channel events on each internal channel are passed to a corresponding output channel that is controlled by a *channel gate*. The channel gate can block propagation of channel events from an internal channel to an output channel.

The output channels from a CTI are combined, using a logical OR function, with the output channels from all other CTIs to form the input channels on other CTIs. The input channels of this CTI are the logical OR of the output channels on all other CTIs. This is the *cross-trigger matrix*, CTM. Therefore, the number of input channels must equal the number of output channels.

———— **Note** ————

The number of input triggers and output triggers is not required to be the same.

The internal channels form an internal cross-trigger matrix within the CTI. This delivers events directly from the input triggers to the output triggers. Therefore the number of internal channels is the same as the number of input and output channels on the external CTM, and there is a direct mapping between the two.

Channel events received on each input channel are passed to the corresponding internal channel. It is IMPLEMENTATION DEFINED whether the cross-trigger gate also blocks propagation of channel events from input channels to internal channels.

When the CTI receives a channel event on an internal channel this generates trigger events on one or more output triggers, according to the mapping function defined by the *Input channel* → *output trigger mapping registers*, `CTIOUTEN<n>`.

The CTI contains the input and output trigger interfaces to the PE and the interface of the cross-trigger matrix. The architecture does not define the signal protocol used on the trigger interfaces, and:

- It is IMPLEMENTATION DEFINED whether the CTI supports multicycle input trigger events.
- It is IMPLEMENTATION DEFINED whether the CTM supports multicycle channel events.

See *Multicycle events*.

However, an output trigger is asserted until acknowledged. The output trigger can be:

- Self-acknowledging. This means that no further action is required from the debugger.
- Acknowledged by the debugger writing 1 to the corresponding bit of `CTIINTACK`.

The time taken to propagate a trigger event from the first PE, through its CTI, across the CTM to another CTI, and thereby to a second PE is IMPLEMENTATION DEFINED.

———— **Note** ————

ARM recommends that this path is not longer than the shortest software communication path between those PEs. This is because if the first PE halts, the Cross-halt trigger event can propagate through the ECT and halt the second PE without causing software on the second PE to malfunction because the first PE is in Debug state and is not responding.

H5.2.1 Multicycle events

A multicycle event is one with a continuous state that might persist over many cycles, as opposed to a discrete event. A typical implementation of a multicycle event is a level-based signal interface, whereas a discrete event might be implemented as a pulse signal or message.

CTI support for multicycle trigger events is IMPLEMENTATION DEFINED. Use of multicycle trigger events is deprecated. Of the architecturally defined input trigger events, the Performance Monitors overflow trigger event and Generic trace external output trigger events can be multicycle input triggers.

CTM support for multicycle channel events is IMPLEMENTATION DEFINED. A CTM that does not support multicycle channel events cannot propagate a multicycle trigger event between CTIs.

———— **Note** ————

A full ECT might comprise a mix of CTIs, some of which can support multicycle trigger events. In bridging these components, multicycle channel events become single channel events at the boundary between the CTIs.

An ECT that supports multicycle trigger events

When an ECT supports multicycle trigger events, an input trigger event to the CTI continuously asserts channel events on all output channels mapped to it until either:

- The input trigger event is removed.
- The channel mapping function is disabled.

This means that an input trigger that is asserted for multiple cycles causes any channels that are mapped to it to become active for multiple cycles. Consequently, any output triggers mapped from that channel are asserted for multiple cycles.

Note

The output trigger remains asserted for at least as long as the channel remains active. This means that even if the output trigger is acknowledged, it remains asserted until the channel deactivates.

The CTI does not guarantee that these events have precisely the same duration, as the triggers and channels can cross between clock domains.

[CTIAPPSET](#) and [CTIAPPCLEAR](#) can set a channel active for multiple cycles. [CTIAPPULSE](#) generates a single channel event. [CTICHINSTATUS](#) and [CTICHOUTSTATUS](#) can report whether a channel is active.

An ECT that does not support multicycle trigger events

When an ECT does not support multicycle trigger events, an input trigger event to the CTI generates a single channel event on all output channels mapped to it, regardless of how long the input trigger event is asserted.

This means that an input trigger event that is asserted for multiple cycles generates a single channel event on any channels mapped to it. Consequently any self-acknowledging output triggers mapped from those channels are single trigger events.

Note

A single event is typically a single cycle, but there is no guarantee that this is always the case.

[CTIAPPSET](#) and [CTIAPPCLEAR](#) can only generate a single channel event. [CTIAPPULSE](#) generates a single channel event. If the ECT does not support multicycle channel events, use of [CTIAPPSET](#) and [CTIAPPCLEAR](#) is deprecated, and the debugger must only use [CTIAPPULSE](#). [CTICHINSTATUS](#) and [CTICHOUTSTATUS](#) must be treated as UNKNOWN.

H5.3 Cross-triggers on a PE in an ARMv8 implementation

An ARMv8 PE must include a cross-trigger interface, and the implementation must include at least the input and output triggers defined in this architecture. The number of channels in the cross-trigger matrix is IMPLEMENTATION DEFINED, but there must be a minimum of three. Software can read CTIDEVID.NUMCHAN to discover the number of implemented channels.

The CTM must connect to all PEs in the same Inner Shareability domain as the ARMv8-A PE, but can also connect to additional PEs. ARM strongly recommends that the CTM connects all PEs implementing a CTI in the system. This includes ARMv7-A PEs and other PEs that can be connected using a CoreSight CTI module.

———— **Note** —————

In a uniprocessor system the CTM is OPTIONAL. The CTM might be connected other CTI modules for non-PEs, such as triggers for system visibility components. ARM recommends that the CTM is implemented.

Any CTI connected to a PE that is not an ARMv8-A PE must implement at least:

- The Debug request trigger event.
- The Restart trigger event.
- The Cross-halt trigger event.

For more information about the CTI, see the *CoreSight™ SoC Technical Reference Manual*. ARMv8-A refines the generic CTI by defining roles for each of the implemented input and output triggers.

H5.4 Description and allocation of CTI triggers

Table H5-1 shows the output trigger events defined by the architecture and the related trigger numbers.

Table H5-1 Allocation of CTI output trigger events

Number	Source	Destination	Event description
0	CTI	PE	<i>Debug request trigger event on page H5-5526</i>
1	CTI	PE	<i>Restart request trigger event on page H5-5526</i>
2	CTI	IRQ controller	<i>Generic CTI interrupt trigger event on page H5-5527</i>
3	-	-	Reserved
4 - 7	CTI	Trace macrocell	OPTIONAL <i>Generic trace external input trigger events on page H5-5527</i>

———— **Note** —————

Output triggers from the CTI are inputs to other blocks.

Table H5-2 shows the input trigger events defined by the architecture and the related trigger numbers.

Table H5-2 Allocation of CTI input trigger events

Number	Source	Destination	Event description
0	PE	CTI	<i>Cross-halt trigger event on page H5-5526</i>
1	PE	CTI	<i>Performance Monitors overflow trigger event on page H5-5527</i>
2 - 3	-	-	Reserved
4 - 7	Trace macrocell	CTI	OPTIONAL <i>Generic trace external output trigger events on page H5-5527</i>

———— **Note** —————

Input triggers to the CTI are outputs from other blocks.

Table H5-1 and Table H5-2 show the minimum set of trigger events defined by the architecture. However:

- The Generic trace external input and output trigger events are only required if the OPTIONAL Trace macrocell is implemented. If the OPTIONAL Trace macrocell is not implemented, these trigger events are reserved.
- Support for the generic CTI interrupt trigger event is IMPLEMENTATION DEFINED because details of interrupt handling in the system, including any interrupt controllers, are IMPLEMENTATION DEFINED. Details regarding how the CTI interrupt is connected to an interrupt controller and its allocated interrupt number lie outside the scope of the architecture. ARM strongly recommends that implementations provide a means to generate interrupts based on external debug events.
- The other trigger events are required by the architecture.

An ARMv8-A implementation can extend the CTI with additional triggers. These start with the number eight.

H5.4.1 Debug request trigger event

This is an output trigger event from the CTI, and an input trigger event to the PE, asserted by the CTI to force the PE into Debug state. The trigger event is asserted until acknowledged by the debugger. The debugger acknowledges the trigger event by writing 1 to [CTIINTACK](#)[0].

———— **Note** —————

A debugger must poll [CTITRIGOUTSTATUS](#)[0] until it reads as 0, to confirm that the output trigger has been deasserted before generating any event that must be ordered after the write to [CTIINTACK](#), such as a write to [CTIAPPULSE](#) to activate another trigger.

If the PE is already in Debug state, the PE ignores the trigger event, but the CTI continues to assert it until it is removed by the debugger. See also [External Debug Request debug event on page H3-5490](#).

H5.4.2 Restart request trigger event

This is an output trigger event from the CTI, and an input trigger event to the PE, asserted by the CTI to request the PE to exit Debug state. If the PE is in Non-debug state, the request is ignored by the PE.

If a Restart request trigger event is received at or about the same time as the PE enters Debug state, it is CONstrained UNPREDICTABLE whether:

- The request is ignored by the PE. In this case the PE enters Debug state and remains in Debug state.
- The PE enters Debug state and then immediately restarts.

Debuggers must program the CTI to send Restart request trigger events only to PEs that are halted. To enable the PE to disambiguate discrete Restart request trigger events, after sending a Restart request trigger event, the debugger must confirm that the PE has restarted and halted before sending another Restart request trigger event. Debuggers can use [EDPRSR](#).{SDR, HALTED} to determine the Execution state of the PE.

———— **Note** —————

Before generating a Restart request trigger event for a PE, a debugger must ensure any Debug request trigger event targeting that PE is cleared. [Debug request trigger event](#) describes how to do this.

The trigger event is self-acknowledging, meaning that the debugger requires no further action to remove the trigger event. The trigger event is acknowledged even if the request is ignored by the PE. See also [Exiting Debug state on page H2-5471](#).

H5.4.3 Cross-halt trigger event

This is an input trigger event to the CTI, and an output trigger event from the PE, asserted by a PE when it is entering Debug state.

———— **Note** —————

To reduce the latency of halting, ARM recommends that an implementation issues the Cross-halt trigger event early in the committed process of entering Debug state. This means that there is no requirement to wait until all aspects of entry to Debug state have completed before issuing the trigger event. Speculative emission of Cross-halt trigger events is not allowed. The Cross-halt trigger event must not be issued early enough for a subsequent Debug request trigger event, that might be derived from the Cross-halt trigger event, to be recorded in the [EDSCR](#).STATUS field. This applies to Debug request trigger events that are acting as inputs to the PE.

H5.4.4 Performance Monitors overflow trigger event

This is an input trigger event to the CTI, and an output trigger event from the PE, asserted each time the PE asserts a new Performance Monitors counter overflow interrupt request. See [Chapter D5 The Performance Monitors Extension](#).

If the CTI supports multicycle trigger events, then the trigger event remains asserted until the overflow is cleared by a write to `PMOVSCLR_ELO`. Otherwise, the trigger event is asserted when the value of `PMOVSCLR_ELO` changes from zero to a non-zero value.

———— **Note** —————

- This does not replace the recommended connection of Performance Monitors overflow trigger event to an interrupt controller. Software must be able to program an interrupt on Performance Monitors overflow without programming the CTI.
- Events can be counted when `ExternalNoninvasiveDebugEnabled()==FALSE`, and, in Secure state, when `ExternalSecureNoninvasiveDebugEnabled()==FALSE`. Secure software must be aware that overflow trigger events are nevertheless visible to the CTI.

H5.4.5 Generic trace external input trigger events

These are output trigger events from the CTI, and input trigger events to the OPTIONAL Trace macrocell, that are used in conjunction with the Generic trace external output trigger events to pass trigger events between:

- The PE and the OPTIONAL Trace macrocell.
- The OPTIONAL Trace macrocell and any other component attached to the CTM, including other Trace macrocells.

There are four Generic trace external input trigger events.

The trigger events are self-acknowledging. This means that the debugger does not have to take any further action to remove the events.

H5.4.6 Generic trace external output trigger events

These are input trigger events to the CTI, and output trigger events from the OPTIONAL Trace macrocell, used in conjunction with the Generic trace external input trigger events to pass trigger events between:

- The PE and the OPTIONAL Trace macrocell.
- The OPTIONAL Trace macrocell and any other component attached to the CTM, including other Trace macrocells.

There are four Generic trace external output trigger events.

H5.4.7 Generic CTI interrupt trigger event

This is an output trigger event from the CTI, and an input to an IMPLEMENTATION DEFINED interrupt controller, and can transfer trigger events from the PE, Trace macrocell, or any other component attached to the CTI and CTM to software as an interrupt. The Generic CTI interrupt trigger event must be connected to the interrupt controller as an interrupt that can target the originating PE.

———— **Note** —————

- ARM recommends that the Generic CTI interrupt trigger event is a private peripheral interrupt, but implementations might instead make this trigger event available as a shared peripheral interrupt or a local peripheral interrupt.
- GICv3 reserves a private peripheral interrupt number for this interrupt.

It is IMPLEMENTATION DEFINED whether this trigger event is:

- Self-acknowledging. This means that the debugger is not required to take any further action, and that the interrupt controller must treat the trigger event as a pulse or edge-sensitive interrupt.
- Acknowledged by the debugger. The debugger acknowledges the trigger event by writing 1 to [CTIINTACK\[2\]](#). This means that the interrupt controller must treat the trigger event as a level-sensitive interrupt.

ARM recommends that the Generic CTI interrupt trigger event is a self-acknowledging trigger event.

H5.5 CTI registers programmers' model

The CTI registers programmers' model is described in [Chapter H8 About the External Debug Registers](#). The following sections contain information specific to the CTI:

- [External debug register resets](#) on page H8-5572.
- [External debug interface register access permissions](#) on page H8-5561.
- [Cross-trigger interface registers](#) on page H8-5570.
- The individual register descriptions in [Cross-Trigger Interface registers](#) on page H9-5677.

See also [Memory-mapped accesses to the external debug interface](#) on page H8-5558.

H5.5.1 CTI reset

An External Debug reset resets the CTI. See [External debug register resets](#) on page H8-5572 for details of CTI register resets. All CTI output triggers and output channels are deasserted on an External Debug reset.

———— **Note** —————

An indirect read of an output trigger might not observe the deasserted state until the processor is Cold reset. For more information, see [Synchronization of changes to the external debug registers](#) on page H8-5554.

H5.5.2 CTI authentication

The CTI ignores the state of the IMPLEMENTATION DEFINED authentication interface. This means that:

- [CTITRIGINSTATUS](#) shows the status of the input triggers and [CTICHINSTATUS](#) shows the status of the input channels, regardless of the value of `ExternalNoninvasiveDebugEnabled()`.

———— **Note** —————

The PE does not generate the Cross-halt trigger event and the Trace macrocell does not generate Generic trace external output trigger events when `ExternalNoninvasiveDebugEnabled()==FALSE`. However, the PE can generate Performance Monitors overflow trigger events.

- The CTI can generate external triggers regardless of the value of `ExternalInvasiveDebugEnabled()`.

———— **Note** —————

The PE ignores Debug request and Restart request trigger events when `ExternalInvasiveDebugEnabled()==FALSE`. The Trace macrocell ignores Generic trace external input trigger events when `ExternalNoninvasiveDebugEnabled()==FALSE`. The behavior of Generic CTI interrupt requests is part of the IMPLEMENTATION DEFINED handling of these interrupts, but it is permissible for an interrupt controller to receive these requests even when `ExternalInvasiveDebugEnabled()==FALSE`.

H5.6 Examples

The CTI is fully programmable and allows for flexible cross-triggering of events within a PE and between PEs in a multiprocessor system. For example:

- The Cross-halt trigger event and the Debug request trigger event can be used for cross-triggering in a multiprocessor system.
- The Cross-halt trigger event and the Generic interrupt trigger event can be used for event-driven debugging in a multiprocessor system.
- The Performance Monitors overflow trigger event and the Debug request trigger event can force entry to Debug state on overflow of a Performance Monitors event counter, for event-driven profiling.

———— **Note** —————

This does not replace the recommended connection of Performance Monitors overflow trigger events to an interrupt controller. Software must be able to program an interrupt on Performance Monitors overflow without programming the CTI. ARM recommends that the Performance Monitors overflow signal is directly available as a local interrupt source.

- The Generic trace external input and Generic trace external output trigger events can pass trace events into and out of the event logic of the Trace macrocell. They can do this:
 - To pass trace events between Trace macrocells.
 - In conjunction with the Performance Monitors overflow trigger event, to couple the Performance Monitors to the Trace macrocell.
 - In conjunction with the Debug request trigger event, to trigger entry to Debug state on a trace event.
 - In conjunction with other CTIs, to signal a trace trigger event onto a CoreSight trace interconnect.

The following sections describe some examples in more detail:

- [Halting a single PE.](#)
- [Halting all PEs in a group when any one PE halts on page H5-5531.](#)
- [Synchronously restarting a group of PEs on page H5-5531.](#)
- [Halting a single PE on Performance Monitors overflow on page H5-5532.](#)

Example H5-1 Halting a single PE

To halt a single PE, set:

1. `CTIGATE[0]` to 0, so that the CTI does not pass channel events on internal channel 0 to the CTM.
2. `CTIOUTEN0[0]` to 1, so that the CTI generates a Debug request trigger event in response to a channel event on channel 0.

———— **Note** —————

The Cross-halt trigger event is input trigger 0, meaning it is controlled by the instance of `CTIOUTEN<n>` for which `<n>` is 0.

3. `CTIAPPULSE[0]` to 1, to generate a channel event on channel 0.

When the PE has entered Debug state, clear the Debug request trigger event by writing 1 to `CTIINTACK[0]`, before restarting the PE.

Example H5-2 Halting all PEs in a group when any one PE halts

To program a group of PEs so that when one PE in the group halts, all of the PEs in that group halt, set the following registers for each PE in the group:

1. `CTIGATE[2]` to 1, so that each CTI passes channel events on internal channel 2 to the CTM.
2. `CTIINEN0[2]` to 1, so that each CTI generates a channel event on channel 2 in response to a Cross-halt trigger event.
3. `CTIOUTEN0[2]` to 1, so that each CTI generates a Debug request trigger event in response to a channel event on channel 2.

———— **Note** —————

The Cross-halt trigger event is input trigger 0, meaning it is controlled by the instances of `CTIINEN<n>` and `CTIOUTEN<n>` for which `<n>` is 0.

When a PE has halted, clear the Debug request trigger event by writing a value of 1 to `CTIINTACK[0]`, before restarting the PE.

Example H5-3 Synchronously restarting a group of PEs

To restart a group of PEs, for each PE in the group:

1. If the PE was halted because of a Debug request trigger event, the debugger must ensure the trigger event is deasserted. It can do this by:
 - a. Writing 1 to `CTIINTACK[0]` to clear the Debug request trigger event.
 - b. Polling `CTITRIGOUTSTATUS[0]`, until it reads as 0, to confirm that the trigger event has been deasserted.
2. Set `CTIGATE[1]` to 1, so that each CTI passes channel events on internal channel 1 to the CTM.
3. Set `CTIOUTEN1[1]` to 1, so that each CTI generates a Restart request trigger event in response to a channel event on channel 1.

———— **Note** —————

This example must use the instance of `CTIOUTEN<n>` for which `<n>` is 1.

4. Set `CTIAPPULSE[1]` to 1 on any one PE in the group, to generate a channel event on channel 1.
-

Example H5-4 Halting a single PE on Performance Monitors overflow

To halt a single PE on a Performance Monitors overflow set:

1. `CTIGATE[3]` to 0, so that the CTI does not pass channel events on internal channel 3 to the CTM.
2. `CTIINEN1[3]` to 1, so that the CTI generates a channel event on channel 3 in response to a Performance Monitors overflow trigger event.

———— **Note** —————

This step of this example must use the instance of `CTIINEN<n>` for which `<n>` is 1.

3. `CTIOUTEN0[3]` to 1, so that the CTI generates a Debug request trigger event in response to a channel event on channel 3.

———— **Note** —————

This step of this example must use the instance of `CTIOUTEN<n>` for which `<n>` is 0.

When the PE has entered Debug state, clear the Debug request trigger event by writing 1 to `CTIINTACK[0]`, before restarting the PE. Clear the overflow status by writing to `PMOVSLR_ELO`.

Chapter H6

Debug Reset and Powerdown Support

This chapter describes the reset and powerdown support in the Debug architecture. It contains the following sections:

- *About Debug over powerdown* on page H6-5534.
- *Power domains and debug* on page H6-5535.
- *Core power domain power states* on page H6-5536.
- *Emulating low-power states* on page H6-5539.
- *Debug OS Save and Restore sequences* on page H6-5541.
- *Reset and debug* on page H6-5545.

———— **Note** —————

Where necessary, [Table K11-1 on page K11-6282](#) disambiguates the general register references used in this chapter.

H6.1 About Debug over powerdown

Debug over powerdown is a facility for an operating system to save and restore the PE state on behalf of a self-hosted or external debugger or both.

For external debug over powerdown, the architecture defines the OS Lock, OS Double Lock, and the logical split of the hardware on which a PE executes into the *Core power domain* and the *Debug power domain*. See:

- [Power domains and debug on page H6-5535](#).
- [Core power domain power states on page H6-5536](#).

H6.2 Power domains and debug

The external debug component of ARMv8-A has two logical power domains, each with its own reset:

- The debug power domain contains the interface between the PE and the external debugger, and is powered up whenever an external debugger is connected to the SoC. It remains powered up while the external debugger is connected. Registers in this domain are reset by an external debug reset.
- The core power domain contains the rest of the PE, and is allowed to power up and power down independently of the Debug power domain.

The core power domain contains several types of registers:

- Non-debug logic refers to all registers and logic that are not associated with debug.
- Self-hosted debug logic refers to registers and logic associated solely with the self-hosted debug aspects of the architecture.
- Shared debug logic refers to registers and logic associated with both the self-hosted and external debug aspects of the architecture.
- External debug logic refers to registers and logic associated solely with the external debug aspects of the architecture.

———— **Note** ————

- The model of two logical power domains has an impact on the reset and access permission requirements of the debug programmers' model.
- The power domains are described as logical because the architecture defines the requirements but does not require two physical power domains. Any power domain split that meets the requirements of the programmers' model is a valid implementation.

Figure H6-1 shows the recommended power domain split. The signals **DBGPWRUPREQ**, **DBGNOPWRDWN**, and **DBGPWRDUP** shown in Figure H6-1 provide an interface between the power controller and the PE debug logic that is in the debug power domain. They are part of the recommended interface. See [Appendix K2 Recommended External Debug Interface](#).

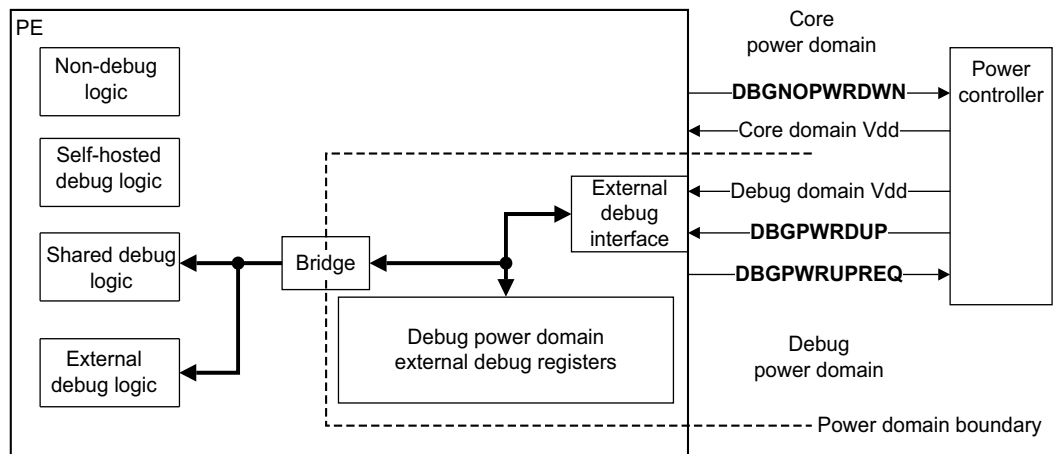

Figure H6-1 Recommended power domain split between core and debug power domains

H6.3 Core power domain power states

The ARM architecture does not define the power states of the PE as these are not normally visible to software. However, they are visible to the external debugger. The Debug architecture uses a four logical power states model for the core power domain. The four logical power states are as follows:

Normal The core power domain is fully powered up and the debug registers are accessible.

Standby The core power domain is on, but there are measures to reduce energy consumption. In a typical implementation, the PE enters standby by executing a WFI or WFE instruction, and exits on a wake-up event. There can be other IMPLEMENTATION DEFINED measures the OS can take to enter standby. The PE preserves the PE state, including the debug logic state. Changing from standby to normal operation does not involve a reset of the PE.

Standby is the least invasive OS energy saving state. Standby implies only that the PE is unavailable and does not clear any debug settings. For standby, the Debug architecture requires only the following:

- An External Debug Request debug event is a wake-up event when halting is allowed. This means that the PE must exit standby to handle the debug event. If the PE executed a WFE or a WFI instruction to enter standby, then it retires that instruction,
- If the external debug interface is accessed, the PE must respond to that access. ARM recommends that, if the PE executed a WFI or WFE instruction to enter standby, then it does not retire that instruction.

Standby is transparent, meaning that to software and to an external debugger it is indistinguishable from normal operation.

Retention The OS takes some measures, including IMPLEMENTATION DEFINED code sequences and registers, to reduce energy consumption. The PE state, including debug settings, is preserved in low-power structures, allowing the core power domain to be at least partially turned off.

Changing from low-power retention to normal operation does not involve a reset of the PE. The saved PE state is restored on changing from low-power retention state to normal operation. If software has to use an IMPLEMENTATION DEFINED code sequence before entering, or after leaving, a retention state, this is referred to as a *software-visible retention state*. It is IMPLEMENTATION DEFINED whether the value of `DBGPRCR.CORENPDRQ` is set to the value of `EDPRCR.COREPURQ` on leaving the software-visible retention state.

External Debug Request debug events stay pending and debug registers in the core power domain cannot be accessed.

Note

- This model of retention does not include implementations where the PE exits the state in response to a debug register access. From the Debug architecture perspective, implementations like this are forms of standby.

Powerdown The OS takes some measures to reduce energy consumption by turning the core power domain off. These measures must include the OS saving any PE state, including the debug settings, that must be preserved over powerdown. Changing from powerdown to normal operation must include:

- A Cold reset of the PE after the power level has been restored.
- The OS restoring the saved PE state.

External Debug Request debug events stay pending and debug registers in the core power domain cannot be accessed.

An implementation might support enabling and disabling threads, either dynamically or once at reset time. Threads that are disabled in this way must appear to the external debugger as either:

- Powered off, meaning they are either:
 - In a powerdown state.
 - In a retention state.
- Held in reset state.

The Debug architecture uses a simpler two states model for the Debug power domain. The two states are:

- Off** The debug power domain is turned off.
- On** The debug power domain is turned on.

The available power states, including the cross-product of core power domain and debug power domain power states is IMPLEMENTATION DEFINED. Implementations are not required to implement all of these states and might include additional states. These additional states must appear to the debugger as one of the logical power states defined by this model. The control of power states is IMPLEMENTATION DEFINED.

———— **Note** —————

As a result, it is IMPLEMENTATION DEFINED whether it is possible for the debug power domain to be on when the core power domain is off.

H6.3.1 EDPRSR.{DLK, SPD, PU} and the Core power domain

Software interprets EDPRSR.{DLK, SPD, PU} to determine whether registers in the Core power domain can be accessed, and whether their state has been lost since the last time the register was read.

Table H6-1 Interpretation of the EDPRSR.{DLK, SPD, PU} bits

EDPRSR			Core power domain			Notes
DLK	SPD	PU	Power	Accesses	State lost	
0	0	1	On	OK	No	-
0	1	1	On	OK	Yes	SPD is cleared to 0 following the read.
1	X	1	On	Error	Not known	OS double-lock is locked. Software locks the OS double-lock before removing power.
X	1	0	Off	Error	Yes	A Cold reset will be asserted on exiting powerdown state, but not on exiting low-power retention state.
X	0	0	Not known	Error	Not known	

If the Core power domain is powered up and DoubleLockStatus() == TRUE, then:

- When ARMv8.2-Debug is not implemented, EDPRSR.{DLK, SPD, PU} can read either {1, UNKNOWN, 1} or {UNKNOWN, 0, 0}.
- **When ARMv8.2-Debug is implemented, EDPRSR.{DLK, SPD, PU} can only read {UNKNOWN, 0, 0}.**

H6.3.2 EDPRSR.SPD when the Core domain is in either retention or powerdown state

When the Core power domain is in either the retention or powerdown state, EDPRSR.SPD is not cleared following a read of EDPRSR and it is IMPLEMENTATION DEFINED whether:

- EDPRSR.SPD shows whether the state of the debug registers in the Core power domain has been lost since the last time that EDPRSR was read. This means that:
 - When the Core power domain is in the powerdown state, EDPRSR.SPD is RAO, this indicates that the state of the debug registers has been lost.
 - When the Core power domain is in the retention state, EDPRSR.SPD indicates whether the state of the debug registers was lost before the Core power domain entered retention state.
- EDPRSR.SPD is RAZ, and:
 - On leaving the powerdown state, EDPRSR.SPD is set to 1 which indicates that the state of the debug registers has been lost.

- On leaving the retention state, `EDPRSR.SPD` reverts the value it had on entering the retention state.

———— **Note** —————

ARM recommends that an implementation makes `EDPRSR.SPD` fixed as RAO when in the power-down state, particularly if it does not support a low-power retention state.

—————

H6.3.3 EDPRSR.{DLK, R} and reset state

`EDPRSR.R` is UNKNOWN when `DoubleLockStatus() == TRUE`. `OSDLR_EL1.DLK` is cleared to 0 by a reset. If the Core power domain is powered up and entered reset state with the OS double-lock locked, it is CONSTRAINED UNPREDICTABLE whether a read of `EDPRSR` while the PE is in reset state returns:

- `EDPRSR.{DLK, R, PU} == {1, UNKNOWN, 1}` indicating that the OS double-lock is locked. **This is not permitted from ARMv8.2.**
- `EDPRSR.{DLK, R, PU} == {0, 1, 1}` indicating that the PE is in reset state.
- `EDPRSR.{DLK, R, PU} == {UNKNOWN, UNKNOWN, 0}` indicating that the registers in the Core power domain cannot be accessed because the OS double-lock is locked.

If the PE was powered up and the OS double-lock was unlocked when the PE was reset, then `EDPRSR.{DLK, R, PU}` reads as `{0, 1, 1}` while the PE is in reset state.

On leaving reset state, `EDPRSR.{DLK, R}` reads as `{0, 0}`.

H6.4 Emulating low-power states

The control registers [DBGPRCR.CORENPDRQ](#) and [EDPRCR.COREPURQ](#) provide an interface between the power controller and the PE. They typically map directly to signals in the recommended external debug interface. With this interface the external debugger can request the power controller to:

- Emulate states where the core power domain is completely off or in a low-power state where the core power domain registers cannot be accessed. This simplifies the requirements on software by sacrificing entirely realistic behavior.
- Restore full power to the core power domain.

[EDPRSR](#).{SPD, PU} indicates the core power domain power state. For more information see:

- [DBGPRCR_EL1, Debug Power Control Register on page D7-2576](#) and [DBGPRCR, Debug Power Control Register on page G6-5298](#).
- [EDPRCR, External Debug Power/Reset Control Register on page H9-5649](#).
- [EDPRSR, External Debug Processor Status Register on page H9-5652](#).
- [Appendix K2 Recommended External Debug Interface](#).

The measures to emulate powerdown are IMPLEMENTATION DEFINED. The ability of the debugger to access the state of the PE and the system might be limited as a result of the measures adopted.

In an emulated powerdown state, the debugger must be able to access all debug, PMU, CTI, and trace unit registers that are accessible on the external debug interface and are in one of:

- The debug power domain.
- The core power domain.
- When a trace unit with a separate trace unit core power domain is implemented, and the trace unit core power domain is powered on, the trace unit core power domain.

That is, the debugger must be able to read and write to such registers without receiving errors. This allows an external debugger to debug the powerup sequence.

ARM recommends that any IMPLEMENTATION DEFINED registers that are on the external debug interface and in either the core power domain or the debug power domain are also accessible in an emulated powerdown state.

To stop the OS Double Lock preventing access to debug registers when powerdown is being emulated, `DoubleLockStatus() == FALSE` when [DBGPRCR.CORENPDRQ](#) == 1.

Otherwise, the behavior of the PE in emulated powerdown must be similar to that in a real powerdown state. In particular, the PE must not respond to other system stimuli, such as interrupts.

[Example H6-1](#) and [Example H6-2](#) are examples of two approaches to emulating powerdown.

Example H6-1 An example of emulating powerdown

The PE is held in Standby state, isolated from any system stimuli. It is IMPLEMENTATION DEFINED whether the PE can respond to debug stimuli such as an External Debug Request debug event.

If the PE can enter Debug state, then the external debugger is able to use the ITR to execute instructions, such as loads and stores. This causes the external debugger to interact with the system. If the external debugger restarts the PE, the PE leaves Standby state and restarts fetching instructions from memory.

Example H6-2 Another example of emulating powerdown

The PE is held in Warm reset. This limits the ability of an external debugger to access the resources of the PE. For example, the PE cannot be put into Debug state.

On exit from emulated powerdown the PE is reset. However, the debug registers that are only reset by a Cold reset must not be reset. Typically this means that a Warm reset is substituted for the Cold reset. As such, the effect of accessing any register that is reset by a Warm reset while the PE is in the emulated powerdown state will have an IMPLEMENTATION DEFINED effect on that register.

Note

- Warm reset and Cold reset have different effects apart from resetting the debug registers. In particular, [RMR_ELx](#) is reset by a Cold reset and controls the reset state on a Warm reset. This means that if a Cold reset is substituted by a Warm reset, the behavior of the reset code might be different.
 - The timing effects of powering down are typically not factored in the powerdown emulation. Examples of these timing effects are clock and voltage stabilization.
 - Emulation does not model the state lost during powerdown, meaning that it might mask errors in the state storage and recovery routines.
-

H6.5 Debug OS Save and Restore sequences

In ARMv8-A, the following registers provide the OS Save and restore mechanism:

- The *OS Lock Access Register*, [OSLAR](#), locks the OS Lock to restrict access to debug registers before starting an OS Save sequence, and unlocks the OS Lock after an OS Restore sequence.
- The *OS Lock Status Register*, [OSLSR](#), shows the status of the OS Lock.
- The *External Debug Execution Control Register*, [EDECR](#), can be configured to generate a debug event when the OS Lock is unlocked.
- The *OS Double Lock Register*, [OSDLR](#), locks out an external debug interface entirely. This is only used immediately before a powerdown sequence.

See also:

- [Reset and debug on page H6-5545](#)
- [Appendix K7 Example OS Save and Restore Sequences](#)

H6.5.1 Debug registers to save over powerdown

[Table H6-2](#) shows the different requirements for self-hosted debug over powerdown and external debug over powerdown:

- The column labeled Self-hosted lists registers that software must preserve over powerdown so that it can support self-hosted debug over powerdown. This does not require use of the OS Save and Restore mechanism.
- The column labeled External lists registers that software must preserve over powerdown so that it can support external debug over powerdown. This requires use of the OS Save and Restore mechanism:
 - Some external debug registers are not normally accessible to software executing on the PE. Additional debug registers are provided that give software the required access to save and restore these external debug registers when [OSLSR.OSLK](#) is locked. These registers include [OSECCR](#), [OSDTRRX](#), and [OSDTRTX](#).
- Some registers might only present in some implementations, or might not be accessible at all Exception levels or in Non-secure state. [DBGVCR32_EL2](#) and [SDER32_EL3](#) are only required to support AArch32.

[Table H6-2](#) does not include registers for the OPTIONAL Trace and Performance Monitor extensions.

Table H6-2 Debug registers to save over powerdown

Register in AArch64 state	Register in AArch32 state	Self-hosted	External
MDCR_EL1	DBGDSCRext	Yes	Yes ^a
DBGBVR<n>_EL1	DBGBVR<n>	Yes	Yes
DBGBCR<n>_EL1	DBGBCR<n>	Yes	Yes
DBGWVR<n>_EL1	DBGWVR<n>	Yes	Yes
DBGWCR<n>_EL1	DBGWCR<n>	Yes	Yes
DBGVCR32_EL2	DBGVCR	Yes	-
MDCR_EL2	HDCR	Yes	-
SDER32_EL3	SDER	Yes	-
MDCR_EL3	SDCR	Yes ^b	-
MDCCINT_EL1	DBGDCCINT	-	Yes ^b

Table H6-2 Debug registers to save over powerdown (continued)

Register in AArch64 state	Register in AArch32 state	Self-hosted	External
DBGCLAIMSET_EL1 DBGCLAIMCLR_EL1	DBGCLAIMSET, DBGCLAIMCLR	-	Yes ^c
OSECCR_EL1	DBGOSECCR	-	Yes ^{ab}
OSDTRRX_EL1 OSDTRTX_EL1	DBGDTRRXext DBGDTRTXext	-	Yes

- The OS Lock must be locked to save and restore for external debug. When the OS Lock is locked, **DSCR** is part of the software save and restore mechanism for external debug. It provides a mechanism for an operating system to access some fields of **EDSCR** that are otherwise read-only or not visible to software. This allows the operating system to save and restore these settings over a powerdown for the external debugger.
- This register is new in ARMv8-A. Sequences written for ARMv7 do not preserve the register over powerdown.
- Read **DBGCLAIMCLR** to save, write **DBGCLAIMSET** to restore.

H6.5.2 OS Save sequence

To preserve the debug logic state over a powerdown, the state must be saved to nonvolatile storage. This means the OS Save sequence must:

- Lock the OS Lock by:
 - Writing the key value 0xC5ACCE55 to the **DBGOSLAR** in AArch32 state.
 - Writing 1 to **OSLAR_EL1.OSLK** in AArch64 state.
- Execute an ISB instruction.
- Walk through the debug registers listed in *Debug registers to save over powerdown on page H6-5541* and save the values to the nonvolatile storage.

Before removing power from the core power domain, software must:

- Lock the OS Double Lock by writing 1 to **OSDLR_EL1.DLK**.
- Execute a *Context synchronization event*.

H6.5.3 OS Restore sequence

After a powerdown, the OS Restore sequence must perform the following steps to restore the debug logic state from the non-volatile storage:

- Lock the OS Lock, as described in *OS Save sequence*. The OS Lock is generally locked by the Cold reset, but this step ensures that it is locked.
- Execute an ISB instruction.
- To ensure that, if an external debugger clears the OS Lock before the end of this sequence, no debug exceptions are generated:
 - Write 0 to **MDSCR_EL1** if executing in AArch64 state.
 - Write 0 to **DBGDSCRExt** if executing in AArch32 state.
- Walk through the debug registers listed in *Debug registers to save over powerdown on page H6-5541*, and restore the values from the nonvolatile storage. The last register to be restored must be:
 - MDSCR_EL1** if executing in AArch64 state.
 - DBGDSCRExt** if executing in AArch32 state.
- Execute an ISB instruction.

6. Unlock the OS Lock by:
 - Writing any non-key value to [DBGOSLAR](#) if executing in AArch32 state.
 - Writing 0 to [OSLAR_EL1.OSLK](#) if executing in AArch64 state.
7. Execute a [Context synchronization event](#).

———— **Note** ————

The OS Restore sequence overwrites the debug registers with the values that were saved. If there are valid values in these registers immediately before the restore sequence, then those values are lost.

H6.5.4 Debug behavior when the OS Lock is locked

The main purpose of the OS Lock is to prevent updates to debug registers during an OS Save or OS Restore operation. The OS Lock is locked on a Cold reset.

When the OS Lock is locked:

- Access to debug registers through the System register interface is mainly unchanged except that:
 - Certain registers are read and written without side-effects.
 - Fields in [DSCR](#) and [OSECCR](#) that are normally read-only become read/write.This allows the state to be saved or restored. For more information, see the relevant register description in [Chapter H9 External Debug Register Descriptions](#).
- Access to debug registers by the external debug interface is restricted to prevent an external debugger modifying the registers that are being saved or restored. For more information see [External debug interface register access permissions summary](#) on page H8-5563.
- Debug exceptions, other than Breakpoint Instruction exceptions are not generated.
- Breakpoint and Watchpoint debug events are not generated. The OS Lock has no effect on Breakpoint Instruction exceptions and other debug events.

H6.5.5 Debug behavior when the OS Lock is unlocked

When the OS Lock is unlocked, the PE sets [EDES.R.OSUC](#) to 1 if [EDES.R.OUCE](#) is set to 1 and the PE is in Non-debug state, meaning the OS Unlock Catch debug event becomes pending. See [OS Unlock Catch debug event](#) on page H3-5491.

H6.5.6 Debug behavior when the OS Double Lock is locked

The OS Double Lock is locked immediately before a powerdown sequence. The OS Double Lock ensures that it is safe to remove core power by forcing the debug interfaces to be quiescent.

When `DoubleLockStatus() == TRUE`:

- The external debug interface only has restricted access to the debug registers, so that it is quiescent before removing power. See [External debug interface register access permissions summary](#) on page H8-5563.
- Debug exceptions, other than Breakpoint Instruction exceptions, are not generated.
- Halting is prohibited. See [Halting allowed and halting prohibited](#) on page H2-5435.

———— **Note** ————

Pending Halting debug events might be lost when core power is removed.

- No asynchronous debug events are WFI or WFE wake-up events.

Software must synchronize the update to [OSDLR](#) before it indicates to the system that core power can be removed. The interface between the PE and its power controller is IMPLEMENTATION DEFINED.

Typically software indicates that core power can be removed by entering the Wait For Interrupt state. This means that software must explicitly synchronize the `OSDLR.DLK` update before issuing the WFI instruction.

`OSDLR.DLK` is ignored and `DoubleLockStatus() == FALSE` if either:

- The PE is in Debug state.
- `DBGPRCR.CORENPDRQ` is set to 1.

———— **Note** —————

It is possible to enter Debug state with `OSDLR.DLK` set to 1. This is because a *Context synchronization event* is required to ensure the OS Double Lock is locked, meaning that Debug state might be entered before the `OSDLR` update is synchronized.

Because `OSDLR.DLK` is ignored when `DBGPRCR.CORENPDRQ` is set to 1, and an external debugger can write to `DBGPRCR.CORENPDRQ`, software must not rely on using the OS Double Lock to disable debug exceptions or to prohibit halting, or both. ARM deprecates use of the OS Double Lock for these purposes, and instead recommends that software:

- Uses the OS Lock to disable debug exceptions during save or restore sequences.
- Uses the debug authentication interface to prohibit halting and external debug access to debug registers at times other than immediately prior to removing power.

As the purpose of the OS Double Lock is to ensure that it is safe to remove core power, it is important to avoid race conditions that defeat this purpose. ARM recommends that:

- Once the write to `OSDLR.DLK` has been synchronized by a *Context synchronization event* and `DoubleLockStatus() == TRUE`, a PE must:
 - Not allow a debug event generated before the *Context synchronization event* to cause an entry to Debug state or act as a wake-up event for a WFI or WFE instruction after the *Context synchronization event* has completed.
 - Complete any external debug access started before the *Context synchronization event* by the time the *Context synchronization event* completes.

———— **Note** —————

A debug register access might be in progress when software sets `OSDLR.DLK` to 1. An implementation must not permit the synchronization of locking the OS Double Lock to stall indefinitely while waiting for that access to complete. This means that any debug register access that is in progress when software sets `OSDLR.DLK` to 1 must complete or return an error in finite time.

- If a write to `DBGPRCR` or `EDPRCR` made when `OSDLR.DLK == 1` changes `DBGPRCR.CORENPDRQ` or `EDPRCR.CORENPDRQ` from 1 to 0, meaning `DoubleLockStatus()` changes from `FALSE` to `TRUE`, then before signaling to the system that the `CORENPDRQ` field has been cleared and emulation of powerdown is no longer requested, meaning the system can remove core power, the PE must ensure that all the requirements for `DoubleLockStatus() == TRUE` listed in this section are met.

In the standard OS Save sequence, the OS Lock is locked before the OS Double Lock is locked. This means that writes to `CORENPDRQ` are ignored by the time the OS Double Lock is locked. However, if `DoubleLockStatus() == FALSE`, an external debugger can clear the OS Lock at any time, and then write to `EDPRCR`.

H6.6 Reset and debug

All registers in the Core power domain are reset either by a Warm reset or a Cold reset, as described in [Reset on page D1-1795](#), including external debug logic registers.

All registers in the Debug power domain are reset by an External Debug reset.

[Figure H6-2](#) shows this reset scheme. The following three reset signals are an example implementation of the reset scheme:

- **CORERESET**, which must be asserted for a Warm reset.
- **CPUPORESET**, which must be asserted for a Cold reset.
- **PRESETDBG**, which must be asserted for an External Debug reset.

As shown in the figure, the external debug logic is split between the Debug power domain and the Core power domain.

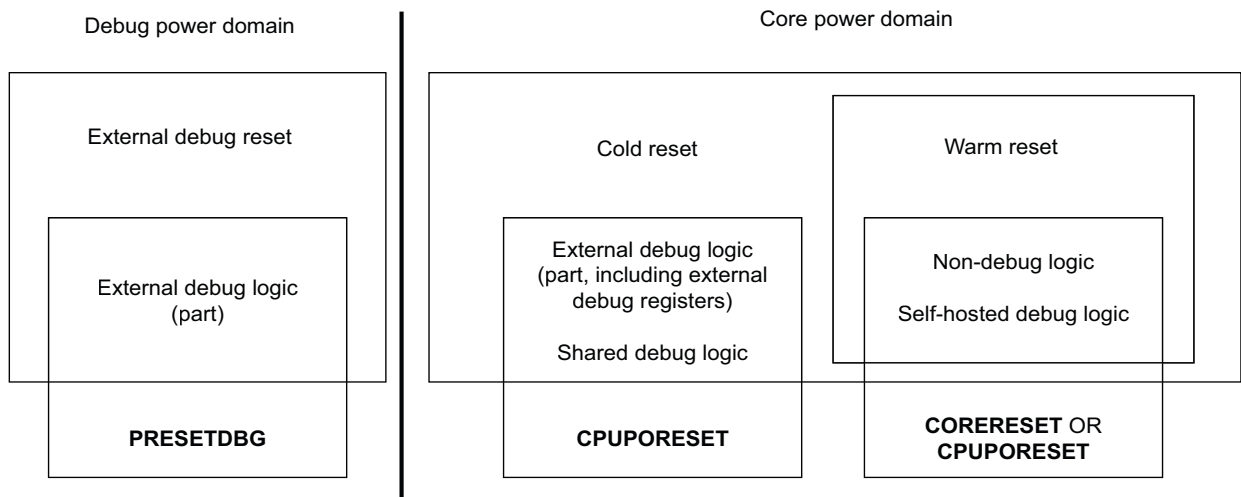

Figure H6-2 Power and reset domains

For more information about power domains and power states, see [Power domains and debug on page H6-5535](#).

When power is first applied to the Debug power domain, **PRESETDBG** must be asserted.

When power is first applied to the Core power domain, **CPUPORESET** must be asserted.

———— **Note** ————

In this scheme, logic in the Warm reset domain is reset by asserting either **CORERESET** or **CPUPORESET**. This implies a particular implementation style that permits these approaches.

CPUPORESET is not normally asserted on moving from a low-power state, where power has not been removed, to a full-power state. This can occur, for example, on exiting a low-power retention state. See also [Emulating low-power states on page H6-5539](#) and [EDPRSR, External Debug Processor Status Register on page H9-5652](#).

H6.6.1 External debug interface accesses to registers in reset

If a reset signal is asserted and the external debug interface:

- Writes a register, or indirectly writes a register or register field as a side-effect of an access:
 - Then, if the register or register field is reset by that reset signal, it is **CONSTRAINED UNPREDICTABLE** whether the register or register field takes the reset value or the value written. The reset value might be **UNKNOWN**.
 - Otherwise the register or register field takes the value that is written.

- Reads a register, or indirectly reads a register or register field, as part of an access:
 - Then, if the register or register field is reset by that reset signal, the value returned is UNKNOWN.
 - Otherwise, the value of the register or register field is returned.

It is IMPLEMENTATION DEFINED whether any register can be accessed when External Debug reset is being asserted. The result of these accesses is IMPLEMENTATION DEFINED.

Chapter H7

The PC Sample-based Profiling Extension

This chapter describes the OPTIONAL PC Sample-based Profiling Extension that provides a non-invasive external debug component.

It contains the following section:

- [About the PC Sample-based Profiling Extension on page H7-5548.](#)

H7.1 About the PC Sample-based Profiling Extension

The PC Sample-based Profiling Extension provides coarse-grained, non-invasive profiling by an external debugger. See also [Non-invasive behavior on page D5-2140](#).

PC Sample-based Profiling creates samples so that tools can populate a statistical model of the performance of software executing on the PE.

Under normal operating conditions, the sample must reference an instruction that was committed for execution, including its context, and must not reference instructions that are fetched but not committed for execution.

It must be possible to sample references to branch targets. It is IMPLEMENTATION DEFINED whether references to other instructions can be sampled. The branch target for a conditional branch instruction that fails its condition check is the instruction that follows the conditional branch instruction. The branch target for an exception is the exception vector address.

To keep the implementation and validation cost low, a reasonable degree of inaccuracy in the sampled data is acceptable. ARM does not define *a reasonable degree of inaccuracy* but recommends the following guidelines:

- In exceptional circumstances, such as a change in Security state or other boundary condition, it is acceptable for the sample to represent an instruction that was not committed for execution.
- Under unusual non-repeating pathological cases, the sample can represent an instruction that was not committed for execution. These cases are likely to occur as a result of asynchronous exceptions, such as interrupts, where the chance of a systematic error in sampling is very unlikely.

———— Note —————

In the ARMv7 PC Sample-based Profiling Extension, an offset was applied to the sampled program counter value and this offset and the instruction set state indicated in bits [1:0] of the sampled value. In the ARMv8 PC Sample-based Profiling Extension, the sampled value is the address of an instruction that has executed, with no offset and no indication of the instruction set state.

H7.1.1 Controlling the PC Sample-based Profiling Extension

PC Sample-based Profiling is controlled by the IMPLEMENTATION DEFINED authentication interface [ExternalNoninvasiveDebugEnabled\(\)](#).

PC Sample-based Profiling is prohibited unless both:

- Allowed by the IMPLEMENTATION DEFINED authentication interface [ExternalNoninvasiveDebugEnabled](#).
- Any one of
 - The PE is executing in Non-secure state.
 - EL3 is not implemented.
 - EL3 is implemented, the PE is executing in Secure state, and allowed by the IMPLEMENTATION DEFINED authentication interface [ExternalSecureNoninvasiveDebugEnabled\(\)](#).
 - EL3 is implemented, EL3 or EL1 is using AArch32, the PE is executing at EL0 in Secure state, and the value of [SDER.SUNIDEN](#) is 1.

The state of the IMPLEMENTATION DEFINED authentication interface is visible through [DBGAUTHSTATUS_EL1](#). See [Recommended authentication interface on page K2-6140](#).

H7.1.2 Registers implemented by the PC Sample-based Profiling Extension

If PC Sample-based Profiling is implemented but not with [ARMv8.2-PCSample](#), [EDDEVID.PCSample](#) and [EDDEVID1.PCSROffset](#) define the level of profiling and the offset.

If PC Sample-based Profiling is implemented but not with [ARMv8.2-PCSample](#) and [ARMv8.1-VHE](#) is implemented, [EDSCR.SC2](#) controls what PC Sample-based Profiling samples.

If PC Sample-based Profiling is implemented but not with [ARMv8.2-PCSample](#), the following external debug registers can be implemented:

- [EDCIDSR](#).
- [EDPCSR](#).
- [EDVIDSR](#).

See *External debug interface register map* on page H8-5565.

If PC Sample-based Profiling is implemented and [ARMv8.2-PCSample](#) is implemented, [PMDEVID.PCSample](#) identifies the level of profiling. The following registers can be implemented in the Performance Monitors external debug page:

- [PMCID1SR](#) and [PMCID2SR](#).
- [PMPCSR](#).
- [PMVIDSR](#).

See *Performance Monitors external register views* on page I3-5746.

In a full [ARMv8.2](#) implementation if the Performance Monitors Extension is not implemented but the PC Sample-based Profiling is implemented with [ARMv8.2-PCSample](#), then the PC Sample-based Profiling Extension is implemented in a separate external debug page. In the memory maps of the [ARMv8-A](#) architecture profile, this page is located at the location that is reserved for the Performance Monitors, see [Table H7-1](#). For [CoreSight](#) compliance, the management registers are defined as in [Table K2-3](#) on page K2-6141 and the support for PC Sample-based profiling is defined in the following registers:

- [PMDEVTYPE.MAJOR](#) has the value 0x0.
- [PMDEVARCH.ARCHID](#) has the value 0x0A10.

Table H7-1 PC Sample-based Profiling register offsets without the Performance Monitors Extension

Offset	Description
0x200	PMPCSR [31:0]
0x204	PMPCSR [63:32]
0x208	PMCID1SR
0x20C	PMVIDSR
0x220	PMPCSR [31:0] (alias)
0x224	PMPCSR [63:32] (alias)
0x228	PMCID1SR (alias)
0x22C	PMCID2SR
0x600-0x6FC	IMPLEMENTATION DEFINED
0xE80-0xEFC	IMPLEMENTATION DEFINED for CoreSight compliance
0xFF0-0xFFC	Management and CoreSight compliance registers

H7.1.3 Pseudocode description of PC Sample-based Profiling

When PC Sample-based Profiling is implemented but not with [ARMv8.2-PCSample](#), the functionality is described by the pseudocode functions:

- [CreatePCSample\(\)](#), which populates a variable of type [PCSample](#).
- [EDPCSRto\[\]](#), which writes a PC sample to the [EDPCSR](#) and associated registers.

Chapter H8

About the External Debug Registers

This chapter provides some additional information about the external debug registers. It contains the following sections:

- *Relationship between external debug and System registers* on page H8-5552.
- *Endianness and supported access sizes* on page H8-5553.
- *Synchronization of changes to the external debug registers* on page H8-5554.
- *Memory-mapped accesses to the external debug interface* on page H8-5558.
- *External debug interface register access permissions* on page H8-5561.
- *External debug interface registers* on page H8-5565.
- *Cross-trigger interface registers* on page H8-5570.
- *External debug register resets* on page H8-5572.

———— **Note** —————

Where necessary [Table K11-1 on page K11-6282](#) disambiguates the general register references used in this chapter.

H8.1 Relationship between external debug and System registers

Table H8-1 shows the relationship between external debug registers and System registers. Where no relationship exists, the registers are not listed.

Table H8-1 Equivalence between external debug and System registers

External debug register	System register		Notes
	AArch64	AArch32	
DBGDTRRX_EL0	DBGDTRRX_EL0	DBGDTRRXint	See also <i>Summary of System register accesses to the DCC</i> on page H4-5509
DBGDTRTX_EL0	DBGDTRTX_EL0	DBGDTRTXint	
OSLAR_EL1	OSLAR_EL1	DBGOSLAR	-
DBGBVR<n>_EL1[31:0]	DBGBVR<n>_EL1[31:0]	DBGBVR<n>	-
DBGBVR<n>_EL1[63:32]	DBGBVR<n>_EL1[63:32]	DBGBXR<n>	
DBGBCR<n>_EL1	DBGBCR<n>_EL1	DBGBCR<n>	-
DBGWVR<n>_EL1[31:0]	DBGWVR<n>_EL1[31:0]	DBGWVR<n>	-
DBGWVR<n>_EL1[63:32]	DBGWVR<n>_EL1[63:32]		
DBGWCR<n>_EL1	DBGWCR<n>_EL1	DBGWCR<n>	-
DBGCLAIMSET_EL1	DBGCLAIMSET_EL1	DBGCLAIMSET	-
DBGCLAIMCLR_EL1	DBGCLAIMCLR_EL1	DBGCLAIMCLR	-
DBGAUTHSTATUS_EL1	DBGAUTHSTATUS_EL1	DBGAUTHSTATUS	Read-only
EDSCR	MDSCR_EL1	DBGDSCRext	Only some fields map
EDECCR	OSECRR_EL1	DBGOSECRR	Applies when the OS Lock is locked.
MIDR_EL1	MIDR_EL1	MIDR	Read-only copies of Processor ID Registers
EDDEVAFF0	MPIDR_EL1[31:0] ^a	MPIDR	Read-only copies of system ID registers
EDDEVAFF1	MPIDR_EL1[63:32] ^a		

a. This is a word of a 64-bit register.

In addition:

- **EDSCR**.{TXfull, RXfull} are read-only aliases for **DCCSR**.{TXfull, RXfull}.
- **EDPRCR**.CORENPDRQ is a read/write alias for **DBGPRCR**.CORENPDRQ.
- **EDPRSR**.OSLK is a read-only alias for **OSLSR**.OSLK.
- **EDPRSR**.DLK is a read-only function of **OSDLR**.DLK.

H8.2 Endianness and supported access sizes

The debug registers, Performance Monitor registers, and CTI registers are implemented as memory-mapped peripherals. The ARM architecture requires memory-mapped peripherals to be little-endian.

The memory access sizes supported by any peripheral is IMPLEMENTATION DEFINED by the peripheral. For accesses to the debug registers, Performance Monitor registers, and CTI registers, implementations must support:

- Word-aligned 32-bit accesses to access 32-bit registers or either half of a 64-bit register mapped to a doubleword-aligned pair of adjacent 32-bit locations.
- Doubleword-aligned 64-bit accesses to access 64-bit registers mapped to a doubleword-aligned pair of adjacent 32-bit locations.

———— **Note** —————

This means that a system implementing the debug registers using a 32-bit bus, such as a AMBA APB3, with a wider system interconnect must implement a bridge between the system and the debug bus that can split 64-bit accesses.

All registers are only single-copy atomic at word granularity. This means that for 64-bit accesses to a 64-bit register, the system might generate a pair of 32-bit accesses. The order in which the two halves are accessed is not specified.

The following accesses are not supported:

- Byte.
- Halfword.
- Unaligned word. These accesses are not word single-copy atomic.
- Unaligned doubleword. These accesses are not doubleword single-copy atomic.
- Doubleword accesses to a pair of 32-bit locations that are not a doubleword-aligned pair forming a 64-bit register.
- Quadword or higher.
- Exclusive accesses.

For each of these access types, it is CONSTRAINED UNPREDICTABLE whether:

- The access generates an external abort or not.
- The defined side-effects of a read occur or not. A read returns UNKNOWN data.
- A write is ignored or sets the accessed register or registers to UNKNOWN.

For accesses from the external debug interface, the size of an access is determined by the interface. For an access from an ADIV5-compliant Memory Access Port, MEM-AP, this is specified by the MEM-AP CSW register.

See [Access sizes for memory-mapped accesses](#) on page H8-5559.

H8.3 Synchronization of changes to the external debug registers

This section describes the synchronization requirements for the external debug interface.

For more information on how these requirements affect debug, see:

- [Synchronization and debug exceptions on page D2-1970](#) for exceptions taken from AArch64 state, or [Synchronization and debug exceptions on page G2-4518](#) for exceptions taken from AArch32 state.
- [Synchronization and Halting debug events on page H3-5494](#).
- [Synchronization of DCC and ITR accesses on page H4-5509](#).

This section refers to accesses from the external debug interface as external reads and external writes. It refers to accesses to System registers as direct reads, direct writes, indirect reads, and indirect writes.

———— Note —————

[Synchronization requirements for AArch64 System registers on page D7-2191](#) defines direct read, direct write, indirect read, and indirect write, and classifies external reads as indirect reads, and external writes as indirect writes.

Writes to the same register are serialized, meaning they are observed in the same order by all observers, although some observers might not observe all of the writes. With the exception of [DBGBCR<n>_EL1](#), [DBGBVR<n>_EL1](#), [DBGWCR<n>_EL1](#), and [DBGWVR<n>_EL1](#), external writes to different registers are not necessarily observed in the same order by all observers as the order in which they complete.

[Synchronization of DCC and ITR accesses on page H4-5509](#) describes the synchronization requirements for the DCC and ITR.

Changes to the IMPLEMENTATION DEFINED authentication interface are external writes to the authentication status registers by the master of the authentication interface. See [Synchronization and the authentication interface on page H8-5555](#).

Explicit synchronization is not required for an external read or an external write by an external agent to be observable to a following external read or external write by that agent to the same register using the same address, and so is never required for registers that are accessible only in the external debug interface.

Some registers are guaranteed to be observable to all observers in finite time, without explicit synchronization. For more information, see [Synchronization requirements for AArch64 System registers on page D7-2191](#) or [Synchronization of changes to AArch32 System registers on page G6-4768](#). Otherwise, explicit synchronization is normally required following an external write to any register for that write to be observable by:

- A direct access.
- An indirect read by an instruction.
- An external read of the register using a different address.

This means that an external write by an external agent is guaranteed to have an effect on subsequent instructions executed by the PE only if all of the following are true:

- The write has completed.
- The PE has executed a [Context synchronization event](#).
- The [Context synchronization event](#) was executed after the write completed.

The order and synchronization of direct reads and direct writes of System registers is defined by [Synchronization requirements for AArch64 System registers on page D7-2191](#).

The external agent must be able to guarantee completion of a write. For example by:

- Marking the memory as Device-nGnRnE and executing a DSB barrier, if the system supports this property.
- Reading back the value written.
- Some guaranteed property of the connection between the PE and the external agent.

———— **Note** ————

For an external Debug Access Port, this is an IMPLEMENTATION DEFINED property. For a CoreSight system using APB-AP to access a debug APB, a write is guaranteed to complete before the APB-AP allows a second APB transaction to complete.

The external agent and PE can guarantee ordering by, for example, passing messages in an ordered way with respect to the external write and the [Context synchronization event](#), and relying on the memory ordering rules provided by the memory model.

External reads and external writes complete in the order in which they arrive at the PE. For accesses to different register locations the external agent must create this order by:

- Marking the memory as Device-nGnRnE or Device-nGnRE.
- Using the appropriate memory barriers.
- Some guaranteed property of the connection between the PE and the external agent.

———— **Note** ————

For an external Debug Access Port, this is an IMPLEMENTATION DEFINED property. For a CoreSight system using APB-AP to access a debug APB, accesses complete in order.

However, the external agent cannot force synchronization of completed writes without halting the PE. Executing an ISB instruction, either in Debug state or in Non-debug state, and exiting from Debug state forces synchronization. If the PE is in Debug state, executing an ISB instruction is guaranteed to explicitly synchronize any external reads, external writes, and changes to the authentication interface that are ordered before the external write to [EDITR](#).

For any given observer, external writes to the following register groups are guaranteed to be observable in the same order in which they complete:

- The breakpoint registers, [DBGBCR<n>_EL1](#) and [DBGBVR<n>_EL1](#).
- The watchpoint registers, [DBGWCR<n>_EL1](#) and [DBGWVR<n>_EL1](#).

This guarantee only applies to external writes to registers within one of these groups. There is no guarantee regarding the ordering of the observability of external writes within these groups with respect to external writes to registers, for example [EDSCR](#), or between breakpoints and watchpoints, including watchpoints linked to context matching breakpoints.

———— **Note** ————

This means that a debugger can rely on the external writes to be observed in the same order in which they complete. It does not mean that a debugger can rely on the external writes being observed in finite time.

In a simple sequential execution an indirect write that occurs as a side-effect of an access happens atomically with the access, meaning no other accesses are allowed between the register access and its side-effect.

If two or more interfaces simultaneously access a register, the behavior must be as if the accesses occurred atomically and in any order. This is described in [Examples of the synchronization of changes to the external debug registers on page H8-5556](#).

Some registers have the property that for certain bits a write of 0 is ignored and a write of 1 has an effect. This means that simultaneous writes must be merged. Registers that have this property and support both external debug and System register access include [DBGCLAIMSET_EL1](#), [DBGCLAIMCLR_EL1](#), [PMCR_EL0](#).{C,P}, [PMOVSSET_EL0](#), [PMOVSLR_EL0](#), [PMCNTENSET_EL0](#), [PMCNTENCLR_EL0](#), [PMINTENSET_EL1](#), [PMINTENCLR_EL1](#), and [PMSWINC_EL0](#). This last register is OPTIONAL and deprecated in the external debug interface.

H8.3.1 Synchronization and the authentication interface

Changes to the authentication interface are indirect writes to the Authentication Status registers by the master of the authentication interface. For each of these Authentication Status registers, it is IMPLEMENTATION DEFINED whether a change on the authentication interface is guaranteed to be observable to an external debug interface read of the register only after a [Context synchronization event](#) or in finite time.

For `DBGAUTHSTATUS_EL1`, a change on the authentication interface is guaranteed to be observable to a System register read of `DBGAUTHSTATUS_EL1` only after a *Context synchronization event*.

H8.3.2 Examples of the synchronization of changes to the external debug registers

[Example H8-1](#), [Example H8-2](#), and [Example H8-3](#) show the synchronization of changes to the external debug registers.

Example H8-1 Order of synchronization of Breakpoint and Watchpoint register writes

Initially `DBGBVR<n>_EL1` is `0x8000` and `DBGBCR<n>_EL1` is `0x0181`. This means that a breakpoint is enabled on the halfword T32 instruction at address `0x8000`.

A sequence of external writes occurs in the following order:

1. `0x0000` is written to `DBGBCR<n>_EL1`, disabling the breakpoint.
2. `0x9000` is written to `DBGBVR<n>_EL1[31:0]`.
3. `0x0061` is written to `DBGBCR<n>_EL1`, enabling a breakpoint on the halfword at address `0x9002`.

The external writes must be observable to indirect reads in the same order as the external writes complete. This means that at no point is there a breakpoint enabled on either of the halfwords at address `0x8002` and `0x9000`.

Similarly a breakpoint or watchpoint must be disabled:

- If both halves of a 64-bit address have to be updated.
- If any of the `DBGBCR<n>_EL1` or `DBGWCR<n>_EL1` fields are modified at the same time as updating the address.

Example H8-2 Simultaneous accesses to DTR registers

Initially `EDSCR.{TXfull, TXU, ERR}` are 0. Then:

- `0x0DCCDA7A` is directly written to `DBGDTRTX_EL0` by an MSR instruction.
- `DBGDTRTX_EL0` is indirectly read by the external debug interface.

These accesses might happen at the same time and in any order.

If the direct write of `0x0DCCDA7A` to `DBGDTRTX_EL0` is handled first, then:

- The external debug interface read of `DBGDTRTX_EL0` clears `EDSCR.TXfull` to 0.
- `EDSCR.{TXU, ERR}` are unchanged.
- The external debug interface read returns `0x0DCCDA7A`.

If the indirect read of `DBGDTRTX_EL0` by the external debug interface is handled first, then:

- The external debug interface read of `DBGDTRTX_EL0` causes an underrun and as a result `EDSCR.{TXU, ERR}` are both set to 1.
- The external debug interface returns an UNKNOWN value.
- Writing `0x0DCCDA7A` to `DBGDTRTX_EL0` sets `DTRTX` to `0x0DCCDA7A` and `EDSCR.TXfull` to 1.

Example H8-3 Simultaneous writes to CLAIM registers

Initially all CLAIM tag bits are 0. Then:

- `0x01` is written to `DBGCLAIMSET_EL1` by a direct write, followed by an explicit *Context synchronization event*.
- `0x02` is written to `DBGCLAIMSET_EL1` by an external write.

These events might happen at the same time and in either order.

After this:

- [DBGCLAIMCLR_EL1](#) is read by a direct read.
- [DBGCLAIMCLR_EL1](#) is read by an external read.

In this case, a direct read can return either 0x01 or 0x03, and the external read can return either 0x02 or 0x03.

The only permitted final result for the CLAIM tags is the value 0x03, because this would be the result regardless of whether 0x01 or 0x02 is written first. This is because the external write is guaranteed to be observable to a direct read in finite time. See *Synchronization requirements for AArch64 System registers* on page D7-2191.

It is not possible for a direct read to return 0x01 and the external read to return 0x02, because the writes to [DBGCLAIMCLR_EL1](#) are serialized.

In the following scenario, there is only one permitted result. Both observers observe the value 0x03, and then, at the same time, two writes occur:

- 0x04 is written to [DBGCLAIMSET_EL1](#) by a direct write, followed by an explicit *Context synchronization event*.
- 0x01 is written to [DBGCLAIMCLR_EL1](#) by an external write.

In this case only permitted final result for the CLAIM tags is the value 0x06.

H8.4 Memory-mapped accesses to the external debug interface

Support for memory-mapped access to the external debug interface is **OPTIONAL**. When memory-mapped access to the external debug interface is supported, the external debug interface is accessed as a little-endian memory-mapped peripheral.

If the external debug interface is CoreSight compliant, then an **OPTIONAL** Software Lock can be implemented for memory-mapped accesses to each component.

The Software Lock is **OPTIONAL** and deprecated. If it is not implemented, the behavior is as if it is unlocked. The Software Locks are controlled by **EDLSR** and **EDLAR**, **PMLSR** and **PMLAR**, and **CTILSR** and **CTILAR**. See *Management registers and CoreSight compliance* on page K2-6141.

With the exception of these registers and the effect of the Software Lock, the behavior of the memory-mapped accesses is the same as for other accesses to the external debug interface.

———— Note ————

The recommended memory-mapped accesses to the external debug interface are not compatible with the memory-mapped interface defined in ARMv7. In particular:

- The memory map is different.
- Memory-mapped accesses do not behave differently to Debug Access Port accesses when **OSLSR.OSLK == 1**, meaning that the OS Lock is locked.

H8.4.1 Register access permissions for memory-mapped accesses

It is **IMPLEMENTATION DEFINED** whether unprivileged memory-mapped accesses are allowed. Privileged software is responsible for controlling memory-mapped accesses using the MMU.

If memory-mapped accesses are made through an ADiv5 interface, the Debug Access Port can block the access using **DBGSWENABLE**. This is outside the scope of the ARMv8-A architecture. See *ARM® Debug Interface Architecture Specification ADiv5.0 to ADiv5.2*.

Effect of the **OPTIONAL** Software Lock on memory-mapped access

For memory-mapped accesses, if other controls permit access to a register, the **OPTIONAL** Software Lock is implemented, and **EDLSR.SLK**, **PMLSR.SLK**, or **CTILSR.SLK** is set to 1, meaning the Software Lock is locked, then with the exception of the LAR itself:

- If other controls permit access to a register, then writes are ignored. That is:
 - Read/write (RW) registers become read-only, writes ignored (RO/WI).
 - Write-only (WO) registers become writes ignored (WI).
- Reads and writes have no side-effects. A side-effect is where a direct read or a direct write of a register creates an indirect write of the same or another register. When the Software Lock is locked, the indirect write does not occur.
- Writes to **EDLAR**, **PMLAR**, and **CTILAR** are unaffected.

This behavior must also apply to all **IMPLEMENTATION DEFINED** registers.

For example, if **EDLSR.SLK** is set to 1:

- **EDSCR**. {TXfull, TXU, ERR} are unchanged by a memory-mapped read from **DBGDTRTX_EL0**.
- **EDSCR**. {RXfull, RXO, ERR} are unchanged by a memory-mapped write to **DBGDTRRX_EL0** that is ignored.
- **EDSCR**. {ITE, ITO, ERR} are unchanged by a memory-mapped write to **EDITR** that is ignored.
- **OSLSR.OSLK** is unchanged by a memory-mapped write to **OSLAR_EL1** that is ignored.

- [EDPCSR\[63:32\]](#), [EDCIDSR](#), and [EDVIDSR](#) are unchanged by a memory-mapped read from [EDPCSR\[31:0\]](#).

———— **Note** ————

Updating [EDVIDSR](#), [EDCIDSR](#), and [EDPCSR](#)hi are side-effects of reading [EDPCSR](#)lo, such that these registers contain the matching context for [EDPCSR](#)lo. The process that updates [EDPCSR](#)lo with PC samples is not a side-effect of the access. Reads of [EDPCSR](#)lo made when the Software Lock is locked can be used to profile software.

- [PMPCSR\[63:32\]](#), [PMCID1SR/PMCID2SR](#), and [PMVIDSR](#) are unchanged by a memory-mapped read from [PMPCSR\[31:0\]](#).

———— **Note** ————

Updating [PMVIDSR](#), [PMCID1SR/PMCID2SR](#), and [PMPCSR\[31:0\]](#) are side-effects of reading [PMPCSR\[63:32\]](#), such that these registers contain the matching context for [PMPCSR\[63:32\]](#). The process that updates [PMPCSR\[63:32\]](#) with PC samples is not a side-effect of the access. Reads of [PMPCSR\[63:32\]](#) made when the Software Lock is locked can be used to profile software.

- [EDPRSR](#) {SDR, SPMAD, SDAD, SR, SPD} are unchanged by a memory-mapped read from [EDPRSR](#).
- [EDPRSR](#).SDAD is not set if an error response is returned due to a memory-mapped read or write of any debug register as the result of the value of the EDAD field.
- The CLAIM tags are unchanged by memory-mapped writes to [DBGCLAIMSET_EL1](#) and [DBGCLAIMCLR_EL1](#) which are ignored.

Similarly, if [PMLSR](#).SLK is set to 1, then [EDPRSR](#).SPMAD is not set if an error response is returned to a memory-mapped read or write of any Performance Monitors register due to the value of the EPMAD field.

Behavior of a not permitted memory-mapped access

Where the architecture requires that an external debug interface access generates an error response, a memory-mapped access must also generate an error response. However, it is IMPLEMENTATION DEFINED how the error response is handled, as this depends on the system.

ARM recommends that the error is returned as either:

- A synchronous external Data Abort.
- An SError interrupt.

H8.4.2 Synchronization of memory-mapped accesses to external debug registers

The synchronization requirements for memory-mapped accesses to the external debug interface is described in [Synchronization of changes to the external debug registers on page H8-5554](#).

The synchronization requirements between different routes to the external debug interface, that is, between Debug Access Port accesses and memory-mapped accesses are IMPLEMENTATION DEFINED.

H8.4.3 Access sizes for memory-mapped accesses

For memory-mapped accesses from a PE that complies with an ARM architecture, the single-copy atomicity rules for the instruction, the type of instruction, and the type of memory accessed, determine the size of the access made by an instruction. [Example H8-4 on page H8-5560](#) shows this.

Example H8-4 Access sizes for memory-mapped accesses

Two Load Doubleword instructions made to consecutive doubleword-aligned locations generate a pair of single-copy atomic doubleword reads. However, if the accesses are made to Normal memory or Device-GRE memory they might appear as a single quadword access that is not supported by the peripheral.

ARMv8 does not require the size of each element accessed by a multi-register load or store instruction to be identifiable by the memory system beyond the PE. Any memory-mapped access to a debug register is defined to be beyond the PE.

Software must use a Device-nGRE or stronger memory-type and use only single register load and store instructions to create memory accesses that are supported by the peripheral. For more information, see [Memory types and attributes on page B2-107](#).

H8.5 External debug interface register access permissions

Some external accesses to debug registers and Performance Monitor registers are not permitted and return an error response if:

- The Core power domain is powered down or is in low-power state where the registers cannot be accessed.
- [OSLSR.OSLK](#) == 1. The OS Lock is locked.
- [DoubleLockStatus\(\)](#) == TRUE. The OS Double Lock is locked.
- Access by the external debug interface is disabled by the authentication interface or secure monitor.

Not all registers are affected in all of these cases. For details, see [External debug interface register access permissions summary](#) on page H8-5563.

———— **Note** —————

[OSLSR.OSLK](#) is visible through [EDPRSR](#).

H8.5.1 External debug over powerdown and locks

Accessing registers using the external debug interface is not possible when the Debug power domain is off. In this case all accesses return an error.

External accesses to debug and Performance Monitors registers in the Core power domain are not permitted and return an error response if:

- The Core power domain is off or in low-power state where the registers cannot be accessed.
- [OSLSR.OSLK](#) == 1, meaning that the OS Lock is locked. This allows software to prevent external debugger modification of the registers while it saves and restores them over powerdown.
- [DoubleLockStatus\(\)](#) == TRUE. This means that the OS Double Lock is locked. The OS Double Lock ensures that it is safe to remove Core power by forcing the debug interface to be quiescent.

It is IMPLEMENTATION DEFINED whether the ID registers that describe the PE to the debugger are in the Debug power domain or the Core power domain.

———— **Note** —————

This applies only to the [MIDR_EL1](#), [EDPFR](#), [EDDFR](#), and [EDAA32PFR](#) registers. It does not include the CoreSight ID registers in the management register address range.

The OS lock condition does not apply to the following debug registers:

- [OSLAR_EL1](#). This means that an external debugger can override this lock.
- [EDESRR](#). This means that an external debugger can program a debug event for when software unlocks the OS lock. See [OS Unlock Catch debug event](#) on page H3-5491.
- The ID registers that describe the PE to the debugger.

See also [Debug registers to save over powerdown](#) on page H6-5541.

H8.5.2 External access disabled

Accesses are further controlled by the external authentication interface. An untrusted external debugger cannot program the breakpoint and watchpoint registers to generate spurious debug exceptions. If external invasive debugging is not enabled, these external accesses to the registers are disabled. If EL3 is implemented, then [SDCR](#) provides additional external access disable controls for those registers if Secure external invasive debugging is disabled.

The disable applies to:

- [DBGBVR<n>_EL1](#), *Debug Breakpoint Value Registers, n = 0 - 15* on page H9-5584.
- [DBGBCR<n>_EL1](#), *Debug Breakpoint Control Registers, n = 0 - 15* on page H9-5580.

- [DBGWVR<n>_EL1, Debug Watchpoint Value Registers, n = 0 - 15](#) on page H9-5600.
- [DBGWCR<n>_EL1, Debug Watchpoint Control Registers, n = 0 - 15](#) on page H9-5597.
- [From ARMv8.2, OSLAR_EL1, OS Lock Access Register](#) on page H9-5675.

In ARMv8.0 and ARMv8.1 implementations, it is IMPLEMENTATION DEFINED whether the disable applies to [OSLAR_EL1](#).

The external debug interface cannot access these registers if either:

- External debugging is not enabled, meaning `ExternalInvasiveDebugEnabled() == FALSE`.
- Secure external debugging is not enabled, meaning `ExternalSecureInvasiveDebugEnabled() == FALSE`, and any of the following:
 - EL3 is not implemented and the implemented Security state is Secure state.
 - EL3 is implemented and `SDCR.EDAD == 1`.

The `AllowExternalDebugAccess()` pseudocode function describes these accessibility rules.

PEs might also provide an OPTIONAL external debug interface to the Performance Monitor registers. The authentication interface and [SDCR](#) provide similar external access disable controls for those registers.

The external debug interface cannot access the Performance Monitor registers if either:

- External non-invasive debug is not enabled. `ExternalNoninvasiveDebugEnabled() == FALSE`.
- Secure external non-invasive debugging is not enabled, `ExternalSecureNoninvasiveDebugEnabled() == FALSE`, and any of:
 - EL3 is not implemented and the implemented Security state is Secure state.
 - EL3 is implemented and `SDCR.EPMAD == 1`.

The `AllowExternalPMUAccess()` pseudocode function describes these accessibility rules.

———— **Note** —————

- ARM recommends that secure software that is not making use of debug hardware does not lock out the external debug interface.
- ARMv8-A does not provide the equivalent control over access to Trace extension registers.

H8.5.3 Behavior of a not permitted access

For an external debug interface access by a Debug Access Port, the Debug Access Port receives the error response and must signal this to the external debugger. For an ADIV5 implementation of a Debug Access Port, the error sets a sticky error flag in the Debug Access Port that the debugger can poll, and that suppresses further accesses until it is explicitly cleared.

When an error is returned because external access is disabled, and this is the highest priority error condition, a sticky error flag in [EDPRSR](#) is indirectly written to 1 as a side-effect of the access:

- For a debug register access when `AllowExternalDebugAccess() == FALSE`, [EDPRSR.SDAD](#) is indirectly written to 1.
- For Performance Monitor register access when `AllowExternalPMUAccess() == FALSE`, [EDPRSR.SPMAD](#) is indirectly written to 1.

The indirect write might not occur for a memory-mapped access to the external debug interface. For more information, see [Register access permissions for memory-mapped accesses](#) on page H8-5558.

If no error is returned, or the error is returned because of a higher priority error condition, the flag in [EDPRSR](#) is unchanged.

See also [Behavior of a not permitted memory-mapped access](#) on page H8-5559.

For more information, see *ARM® Debug Interface Architecture Specification*.

H8.5.4 Trapping software access to debug registers

When `EDSCR.TDA == 1`, software access to the breakpoint and watchpoint registers generate a Halting debug event and entry to Debug state. For more information see [Software Access debug event on page H3-5493](#).

H8.5.5 External debug interface register access permissions summary

For accesses to:

- IMPLEMENTATION DEFINED registers, see [IMPLEMENTATION DEFINED registers](#).
- OPTIONAL registers for CoreSight compliance, see [OPTIONAL CoreSight management registers](#).
- Reserved, unallocated, or unimplemented registers, writes to read-only registers, and reads of write-only registers, see [Reserved and unallocated registers](#).

For all other external debug interface, CTI, and Performance Monitor registers, [Table H8-3 on page H8-5568](#), [Table H8-4 on page H8-5570](#) and [Table I2-1 on page I2-5740](#), show the response of the PE to accesses by the external debug interface.

H8.5.6 IMPLEMENTATION DEFINED registers

For debug registers, Performance Monitors registers, CTI registers, IMPLEMENTATION DEFINED register access permissions are IMPLEMENTATION DEFINED. The power domain in which these registers are implemented is also IMPLEMENTATION DEFINED.

If OPTIONAL memory-mapped access to the external debug interface is supported, there are additional constraints on memory-mapped accesses to registers. These constraints must also apply to IMPLEMENTATION DEFINED registers. In particular, if the OPTIONAL Software Lock is locked, writes are ignored and accesses have no side-effects. For more information see [Register access permissions for memory-mapped accesses on page H8-5558](#).

H8.5.7 OPTIONAL CoreSight management registers

Compliance with CoreSight architecture requires additional registers in the range `0xF00 - 0xFFC` that are always accessible. See [Management registers and CoreSight compliance on page K2-6141](#).

H8.5.8 Reserved and unallocated registers

The following information relates to certain types of reserved accesses:

- Reads and writes of unallocated locations. These accesses are reserved for the architecture.
- Reads and writes of locations for features that are not implemented, including:
 - OPTIONAL features that are not implemented.
 - Breakpoints and watchpoints that are not implemented.
 - Performance Monitors counters that are not implemented.
 - CTI triggers that are not implemented.

These accesses are reserved.

- Reads of WO locations. These accesses are reserved for the architecture.
- Writes to RO locations. These accesses are reserved for the architecture.

Reserved accesses normally RAZ/WI. However, software must not rely on this property as the behavior of reserved values might change in a future revision of the architecture.

———— **Note** —————

Reads of WO and writes to RO refers to the default access permissions for a register. For example, when the SLK field is set, meaning that the relevant registers become RO, a memory-mapped write to a RW register is ignored, and not treated as a reserved access.

The following reserved registers are RES0 in all conditions, other than when debug power is off:

- If the implementation is CoreSight architecture compliant, all reserved registers in the range 0xF00 - 0xFFC. See [Management register access permissions on page K2-6142](#).
- All reserved CTI registers.

Otherwise, the architecture defines that:

1. If debug power is off, all register accesses, including reserved accesses, return an error.
2. For reserved debug registers and Performance Monitors registers, the response is a CONSTRAINED UNPREDICTABLE choice of error or RES0, when any of the following hold:
 - Off** The Core power domain is either completely off or in a low-power state in which the Core power domain registers cannot be accessed.
 - DLK** DoubleLockStatus() == TRUE. The OS Double Lock is locked.
 - OSLK** OSLSR.OSLK == 1. The OS Lock is locked.
3. In addition, for reserved debug registers in the address ranges 0x400 - 0x4FC and 0x800 - 0x8FC, the response is a CONSTRAINED UNPREDICTABLE choice of error or RES0 when conditions 1 or 2 do not apply and:
 - EDAD** AllowExternalDebugAccess() == FALSE. External debug is disabled.

———— **Note** —————

See also [Behavior of a not permitted access on page H8-5562](#).

4. In addition, for reserved Performance Monitors registers in the address ranges 0x000 - 0x0FC and 0x400 - 0x47C, the response is a CONSTRAINED UNPREDICTABLE choice of error or RES0 when conditions 1 or 2 do not apply and:
 - EPMAD** AllowExternalPMUAccess() == FALSE. External Performance Monitor access is disabled.

———— **Note** —————

See also [Behavior of a not permitted access on page H8-5562](#).

H8.6 External debug interface registers

The external debug interface register map is described by:

- *Performance Monitors external register views* on page I3-5746.
- *Cross-trigger interface registers* on page H8-5570.
- *External debug interface register map*.

Table H8-2 External debug interface register map

Offset	Mnemonic	Register, or additional information

- a. **Supported only if the OPTIONAL PC Sample-Based Profiling is implemented but ARMv8.2-PCSample is not implemented. See Chapter H7 The PC Sample-based Profiling Extension.**
Implemented only if the OPTIONAL PC Sample-based Profiling Extension is implemented.
- b. A 64-bit register mapped to a pair of 32-bit locations. Doubleword accesses to this register are not guaranteed to be 64-bit single copy atomic. See *Endianness and supported access sizes on page H8-5553*. Software must ensure a breakpoint or watchpoint is disabled before altering the value register.
- c. Implemented breakpoints and watchpoints only. *n* is the breakpoint or the watchpoint number.

————— Note —————
All other locations are reserved.

H8.6.1 Access permissions for the External debug interface registers

Table H8-3 on page H8-5568 shows the access permissions for the external debug interface registers in an ARMv8-A Debug implementation. The terms are defined as follows:

Domain	This describes the power domain in which the register is logically implemented. Registers described as implemented in the Core power domain might be implemented in the Debug power domain, as long as they exhibit the required behavior.
Conditions	This lists the conditions under which the access is attempted. To determine the access permissions for a register, read these columns from left to right, and stop at first column which lists the condition as being true. The conditions are:
Off	<code>EDPRSR.PU == 0</code> . The Core power domain is completely off, or in low-power state. In these cases the Core power domain registers cannot be accessed.
Note	
If debug power is off, then all external debug interface accesses return an error.	
DLK	<code>DoubleLockStatus() == TRUE</code> . The OS Double Lock is locked.
OSLK	<code>OSLSR.OSLK == 1</code> . The OS Lock is locked.
EDAD	<code>AllowExternalDebugAccess() == FALSE</code> . External debug access is disabled. See also <i>Behavior of a not permitted access on page H8-5562</i> .
EPMAD	<code>AllowExternalPMUAccess() == FALSE</code> . Access to the external Performance Monitors is disabled. See also <i>Behavior of a not permitted access on page H8-5562</i> .
SLK	This provides the modified default access permissions for OPTIONAL memory-mapped accesses to the external debug interface if the OPTIONAL Software Lock is locked. See <i>Register access permissions for memory-mapped accesses on page H8-5558</i> . For all other accesses, this column is ignored.
Default	This provides the default access permissions, if there are no conditions that prevent access to the register.

The access permissions are:

-	This means that the default access permission applies. See the Default column, or the SLK column, if applicable.
RO	This means that the register or field is read-only, and: <ul style="list-style-type: none"> Unless the register description states otherwise, a RO field in an RW register ignores writes. Where the SLK control makes a RW register RO, the register ignores writes.
RW	This means that the register or field is read/write. Individual fields within the register might be RO or WO. See the relevant register description for details.
RC	This means that a read of the register bit clears the field to 0.
WO	This means that the register or field is write-only. Unless the register description states otherwise, a WO field in a RW register returns an UNKNOWN value on a read of the register.
WI	This means that the register or field ignores writes.
IMP DEF	This means that the access permissions are IMPLEMENTATION DEFINED.

If OPTIONAL memory-mapped access to the external debug interface is supported, there might be additional constraints on memory-mapped accesses. See [Register access permissions for memory-mapped accesses on page H8-5558](#).

Table H8-3 Access permissions for the external debug interface registers

Offset	Register	Domain	Conditions (priority from left to right)				Default	SLK

- a. Implemented only if the PC Sample-based profiling Extension is implemented.
- b. It is IMPLEMENTATION DEFINED whether an error is returned. See [External access disabled on page H8-5561](#). If no error is returned, the access is permitted.
- c. Some control bits are in the Core power domain. These bits ignore writes when Core power domain registers cannot be accessed as shown.
- d. Some status bits are fetched from the Core power domain. These bits read UNKNOWN when Core power domain registers cannot be accessed as shown.
- e. Implemented breakpoints and watchpoints only. *n* is the breakpoint or watchpoint number.
- f. It is IMPLEMENTATION DEFINED whether an error is returned. See [External debug over powerdown and locks on page H8-5561](#). If no error is returned, the access is permitted.

For the reset values for the external debug interface registers, see [Table H8-6 on page H8-5572](#).

H8.7 Cross-trigger interface registers

The embedded Cross-trigger Interface, CTI, is located within its own block of the external debug memory map. There must be one such block for each PE.

If the CTI of a PE does not implement the [CTIDEVAFF0](#) or [CTIDEVAFF1](#) registers it must be located 64KB above the debug registers in the external debug interface.

[Table H8-4](#) shows the CTI register map.

Table H8-4 Cross-trigger interface map

Offset	Mnemonic	Location of further details
0x000	CTICONTROL	CTICONTROL , CTI Control register on page H9-5692
0x010	CTIINTACK	CTIINTACK , CTI Output Trigger Acknowledge register on page H9-5705
0x014	CTIAPPSET	CTIAPPSET , CTI Application Trigger Set register on page H9-5681
0x018	CTIAPPCLEAR	CTIAPPCLEAR , CTI Application Trigger Clear register on page H9-5679

0xFC0	CTIDEVID2	CTIDEVID2 , CTI Device ID register 2 on page H9-5701
0xFC4	CTIDEVID1	CTIDEVID1 , CTI Device ID register 1 on page H9-5700
0xFC8	CTIDEVID	CTIDEVID , CTI Device ID register 0 on page H9-5698
0xFD0 – 0xFFC	Management registers	Management registers and CoreSight compliance on page K2-6141

a. Implemented triggers, including triggers that are not connected, only. n is the trigger number.

Table H8-5 shows the access permissions for the CTI registers in an ARMv8-A Debug implementation. For a definition of the terms used, see [External debug interface registers on page H8-5565](#).

Table H8-5 Access permissions for the CTI registers

Offset	Register	Domain	Conditions (priority from left to right)				Default	SLK
			Off	DLK	OSLK	EDAD		
0x000	CTICONTROL	Debug	-	-	-	-	RW	RO
0x010	CTIINTACK	Debug	-	-	-	-	WO	WI
0x014	CTIAPPSET	Debug	-	-	-	-	RW	RO
0x018	CTIAPPCLEAR	Debug	-	-	-	-	WO	WI
0x01C	CTIAPPULSE	Debug	-	-	-	-	WO	WI
0x020+4×n	CTIINEN<n>^a	Debug	-	-	-	-	RW	RO
0x0A0+4×n	CTIOUTEN<n>	Debug	-	-	-	-	RW	RO
0x130	CTITRIGINSTATUS	Debug	-	-	-	-	RO	RO
0x134	CTITRIGOUTSTATUS	Debug	-	-	-	-	RO	RO
0x138	CTICHINSTATUS	Debug	-	-	-	-	RO	RO
0x13C	CTICHOUTSTATUS	Debug	-	-	-	-	RO	RO
0x140	CTIGATE	Debug	-	-	-	-	RW	RO
0xFC0	CTIDEVID2	Debug	-	-	-	-	RO	RO
0xFC4	CTIDEVID1	Debug	-	-	-	-	RO	RO
0xFC8	CTIDEVID	Debug	-	-	-	-	RO	RO

a. Implemented triggers only (including triggers that are not connected). *n* is the trigger number.

For the reset values of the CTI registers, see [Table H8-7 on page H8-5574](#).

H8.8 External debug register resets

Each register or field has a defined reset domain:

- Registers and fields in the Warm reset domain are also reset by a Cold reset and unchanged by an External Debug reset that is not coincident with a Cold reset or a Warm reset.
- Registers and fields in the Cold reset domain are unchanged by a Warm reset or an External Debug reset that is not coincident with a Cold reset.
- Registers and fields in the External Debug reset domain are unchanged by a Cold reset or a Warm reset that is not coincident with an External Debug reset.

A reset might change the value of a register. Specific rules apply to the observability of registers in the External Debug reset domain by indirect reads from the Core power domain when an External Debug reset is asserted without a coincident Cold reset. For more information, see [Synchronization of changes to the external debug registers on page H8-5554](#).

[Table H8-6](#) and [Table H8-7 on page H8-5574](#) show the external debug register and CTI register resets. For other debug registers and Performance Monitors registers, see [Management register resets on page K2-6146](#) and [Power domains and Performance Monitors registers reset on page I2-5741](#).

———— **Note** —————

By reference to [Figure H6-2 on page H6-5545](#) the power domain can be deduced from the reset domain. [Table K2-7 on page K2-6146](#) also shows reset power domains.

[Table H8-6](#) and [Table H8-7 on page H8-5574](#) do not include:

- Read-only identification registers, such as Processor ID Registers and [PMCFGR](#), that have a fixed value from reset.
- Read-only status registers, such as [EDSCR.RW](#), that are evaluated each time the register is read and that have no meaningful reset value.
- Write-only registers, such as [EDRCR](#), that only have an effect on writes, and have no meaningful reset value.
- Read/write registers, such as breakpoint and watchpoint registers, and [EDPRCR.CORENPDRQ](#), that alias other registers. The reset values are described by the descriptions of those other registers.
- IMPLEMENTATION DEFINED registers. The reset values and reset domains of these registers are also IMPLEMENTATION DEFINED and might be UNKNOWN.

All other fields in the registers are set to an IMPLEMENTATION DEFINED value, that can be UNKNOWN. The register is in the specified reset domain.

———— **Note** —————

An IMPLEMENTATION DEFINED reset value, which can be UNKNOWN, means that hardware is not required to reset the register on the specified reset, but software must not rely on the register being preserved over reset.

Table H8-6 Summary of external debug register resets, debug registers

Register	Reset domain	Field	Value	Description
EDES _R	Warm	SS	EDECR.SS	Halting Step debug event pending
		RC	EDECR.RCE	Reset Catch debug event pending
		OSUC	0	OS Unlock Catch debug event pending

Table H8-6 Summary of external debug register resets, debug registers (continued)

Register	Reset domain	Field	Value	Description
EDECR	External debug	SS	0	Halting Step debug event enable
		RCE	0	Reset Catch debug event enable
		OSUCE	0	OS Unlock Catch debug event enable
EDWAR	Cold	-	-	All fields
EDSCR	Cold	RXfull	0	DTRRX register full
		TXfull	0	DTRTX register full
		RXO	0	DTRRX overrun
		TXU	0	DTRTX underrun
		INTdis	0	Interrupt disable
		TDA	0	Trap debug register accesses to Debug state
		MA	0	Memory access mode in Debug state
		HDE	0	Halting debug mode enable
		ERR	0	Cumulative error flag
EDECCR	Cold	NSE[2:1]	0b00	Coarse-grained Non-secure Exception Catch
		SE[3,1]	0b00	Coarse-grained Secure Exception Catch
EDPCSR	Cold	-	-	All fields
EDCIDSR	Cold	-	-	All fields
EDVIDSR	Cold	-	-	All fields
EDPRCR	External debug	COREPURQ ^a	0	Core powerup request
EDPRSR	Warm	SDR	-	Sticky debug restart
	Cold	SPMAD	0	Sticky EPMAD error
		SDAD	0	Sticky EDAD error
	Warm	SR	1	Sticky reset status
	Cold	SPD	1	Sticky powerdown status

- a. On a cold reset into AArch64 state, [DBGPRCR_EL1.CORENPRDRQ](#) resets to the value of [EDPRCR.COREPURQ](#). On a cold reset into AArch32 state, [DBGPRCR.CORENPRDRQ](#) resets to the value of [EDPRCR.COREPURQ](#). If an External Debug reset and a Cold reset coincide, both [EDPRCR.COREPURQ](#) and the [CORENPRDRQ](#) field of the appropriate System register are reset to 0.

Table H8-7 shows the reset values for the CTI registers

Table H8-7 Summary of external debug register resets, CTI registers

Register	Reset domain	Field	Value	Description
CTICONTROL	External debug	GLBEN	0	CTI global enable
CTIAPPSET	External debug	-	-	All fields
CTIINEN<n>	External debug	-	-	All fields
CTIOUTEN<n>	External debug	-	-	All fields
CTIGATE	External debug	-	-	All fields
ASICCTL	IMPLEMENTATION DEFINED	-	IMPLEMENTATION DEFINED	All of register

Chapter H9

External Debug Register Descriptions

This chapter provides a description of the external debug registers.

It contains the following sections:

- [About the debug registers on page H9-5576.](#)
- [External debug registers on page H9-5577.](#)
- [Cross-Trigger Interface registers on page H9-5677.](#)

H9.1 About the debug registers

The following sections describe the registers that are accessible through the external debug interface:

- [External debug registers on page H9-5577.](#)
- [Cross-Trigger Interface registers on page H9-5677.](#)

H9.2 External debug registers

This section describes the debug registers that are accessible through the external debug interface and are used for external debug.

This section lists the registers that are accessible through the external debug interface.

H9.2.1 DBGAUTHSTATUS_EL1, Debug Authentication Status register

The DBGAUTHSTATUS_EL1 characteristics are:

Purpose

Provides information about the state of the IMPLEMENTATION DEFINED authentication interface for debug.

Usage constraints

This register is accessible as follows:

Default

RO

Configurations

External register DBGAUTHSTATUS_EL1 is architecturally mapped to AArch64 System register [DBGAUTHSTATUS_EL1](#).

External register DBGAUTHSTATUS_EL1 is architecturally mapped to AArch32 System register [DBGAUTHSTATUS](#).

DBGAUTHSTATUS_EL1 is in the Debug power domain.

Attributes

DBGAUTHSTATUS_EL1 is a 32-bit register.

Field descriptions

The DBGAUTHSTATUS_EL1 bit assignments are:

Bits [31:8]

Reserved, RES0.

SNID, bits [7:6]

Secure non-invasive debug. Possible values of this field are:

- 00 Not implemented. EL3 is not implemented and the implemented Security state is Non-secure state.
- 10 Implemented and disabled. ExternalSecureNoninvasiveDebugEnabled() == FALSE.
- 11 Implemented and enabled. ExternalSecureNoninvasiveDebugEnabled() == TRUE.

Other values are reserved.

SID, bits [5:4]

Secure invasive debug. Possible values of this field are:

- 00 Not implemented. EL3 is not implemented and the implemented Security state is Non-secure state.
- 10 Implemented and disabled. ExternalSecureInvasiveDebugEnabled() == FALSE.
- 11 Implemented and enabled. ExternalSecureInvasiveDebugEnabled() == TRUE.

Other values are reserved.

NSNID, bits [3:2]

Non-secure non-invasive debug. Possible values of this field are:

- 00 Not implemented. EL3 is not implemented and the implemented Security state is Secure state.
- 10 Implemented and disabled. ExternalNoninvasiveDebugEnabled() == FALSE.
- 11 Implemented and enabled. ExternalNoninvasiveDebugEnabled() == TRUE.

Other values are reserved.

NSID, bits [1:0]

Non-secure invasive debug. Possible values of this field are:

- 00 Not implemented. EL3 is not implemented and the implemented Security state is Secure state.
- 10 Implemented and disabled. ExternalInvasiveDebugEnabled() == FALSE.
- 11 Implemented and enabled. ExternalInvasiveDebugEnabled() == TRUE.

Other values are reserved.

Accessing the DBGAUTHSTATUS_EL1:

DBGAUTHSTATUS_EL1 can be accessed through the external debug interface:

Component	Offset
Debug	0xFB8

H9.2.2 DBGBCR<n>_EL1, Debug Breakpoint Control Registers, n = 0 - 15

The DBGBCR<n>_EL1 characteristics are:

Purpose

Holds control information for a breakpoint. Forms breakpoint n together with value register [DBGBVR<n>_EL1](#).

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	EDAD	SLK	Default
Error	Error	Error	Error	RO	RW

Configurations

External register DBGBCR<n>_EL1 is architecturally mapped to AArch64 System register [DBGBCR<n>_EL1](#).

External register DBGBCR<n>_EL1 is architecturally mapped to AArch32 System register [DBGBCR<n>](#).

DBGBCR<n>_EL1 is in the Core power domain. RW fields in this register reset to architecturally UNKNOWN values. These apply only on a Cold reset. The register is not affected by a Warm reset and is not affected by an External debug reset.

If breakpoint n is not implemented then this register is unallocated.

Attributes

DBGBCR<n>_EL1 is a 32-bit register.

Field descriptions

The DBGBCR<n>_EL1 bit assignments are:

When the E field is zero, all the other fields in the register are ignored.

Bits [31:24]

Reserved, RES0.

BT, bits [23:20]

Breakpoint Type. Possible values are:

- 0000 Unlinked instruction address match.
- 0001 Linked instruction address match.
- 0010 Unlinked Context ID match.
- 0011 Linked Context ID match.
- 0100 Unlinked instruction address mismatch.
- 0101 Linked instruction address mismatch.

0110	Unlinked <code>CONTEXTIDR_EL1</code> match (introduced in ARMv8.1).
0111	Linked <code>CONTEXTIDR_EL1</code> match (introduced in ARMv8.1).
1000	Unlinked VMID match.
1001	Linked VMID match.
1010	Unlinked VMID and Context ID match.
1011	Linked VMID and Context ID match.
1100	Unlinked <code>CONTEXTIDR_EL2</code> match (introduced in ARMv8.1).
1101	Linked <code>CONTEXTIDR_EL2</code> match (introduced in ARMv8.1).
1110	Unlinked Full Context ID match (introduced in ARMv8.1).
1111	Linked Full Context ID match (introduced in ARMv8.1).

The field breaks down as follows:

- BT[3:1]: Base type.
 - 000 Match address. `DBGBVR<n>_EL1` is the address of an instruction.
 - 001 Match Context ID. `DBGBVR<n>_EL1.ContextID` is a Context ID compared against `CONTEXTIDR_EL1` when `ARMv8.1-VHE` is not implemented, or not in a Host OS or a Host Application. When `ARMv8.1-VHE` is implemented, and in a Host OS or Host Application, the Context ID is compared against `CONTEXTIDR_EL2`.
 - 010 Mismatch address. `DBGBVR<n>_EL1` is the address of an instruction to be stepped.
 - 011 Match `CONTEXTIDR_EL1`. `DBGBVR<n>_EL1.ContextID` is a Context ID compared against `CONTEXTIDR_EL1`.
 - 100 Match VMID. `DBGBVR<n>_EL1.VMID` is a VMID compared against `VTTBR_EL2.VMID`.
 - 101 Match VMID and Context ID. `DBGBVR<n>_EL1.ContextID` is a Context ID compared against `CONTEXTIDR_EL1`, and `DBGBVR<n>_EL1.VMID` is a VMID compared against `VTTBR_EL2.VMID`.
 - 110 Match `CONTEXTIDR_EL2`. `DBGBVR<n>_EL1.ContextID2` is a Context ID compared against `CONTEXTIDR_EL2`.
 - 111 Match Full Context ID. `DBGBVR<n>_EL1.ContextID` is compared against `CONTEXTIDR_EL1`, and `DBGBVR<n>_EL1.ContextID2` is compared against `CONTEXTIDR_EL2`.
- BT[0]: Enable linking.

Constraints on breakpoint programming mean some values are reserved under certain conditions. For more information, see [Reserved `DBGBCR<n>_EL1.BT` values on page D2-1935](#).

This field resets to a value that is architecturally UNKNOWN.

LBN, bits [19:16]

Linked breakpoint number. For Linked address matching breakpoints, this specifies the index of the Context-matching breakpoint linked to.

For all other breakpoint types this field is ignored and reads of the register return an UNKNOWN value.

This field is ignored when the value of `DBGBCR<n>_EL1.E` is 0.

This field resets to a value that is architecturally UNKNOWN.

SSC, bits [15:14]

Security state control. Determines the Security states under which a Breakpoint debug event for breakpoint n is generated. This field must be interpreted along with the HMC and PMC fields, and there are constraints on the permitted values of the {HMC, SSC, PMC} fields. For more information, including the effect of programming the fields to a reserved set of values, see [Reserved DBGBCR<n>_EL1.{SSC, HMC, PMC} values on page D2-1936](#).

This field resets to a value that is architecturally UNKNOWN.

HMC, bit [13]

Higher mode control. Determines the debug perspective for deciding when a Breakpoint debug event for breakpoint n is generated. This field must be interpreted along with the SSC and PMC fields, and there are constraints on the permitted values of the {HMC, SSC, PMC} fields. For more information see [DBGBCR<n>_EL1.SSC](#) description.

This field resets to a value that is architecturally UNKNOWN.

Bits [12:9]

Reserved, RES0.

BAS, bits [8:5]

Byte address select. Defines which half-words an address-matching breakpoint matches, regardless of the instruction set and Execution state. In an AArch64-only implementation, this field is reserved, RES1.

The permitted values depend on the breakpoint type.

For Address match breakpoints in either AArch32 or AArch64 state, the permitted values are:

BAS	Match instruction at	Constraint for debuggers
0011	DBGBVR<n>_EL1	Use for T32 instructions.
1100	DBGBVR<n>_EL1+2	Use for T32 instructions.
1111	DBGBVR<n>_EL1	Use for A64 and A32 instructions.

All other values are reserved.

For more information, see [Using the BAS field in Address Match breakpoints on page G2-4483](#).

For Address mismatch breakpoints in an AArch32 stage 1 translation regime, the permitted values are:

BAS	Step instruction at	Constraint for debuggers
0000	-	Use for a match anywhere breakpoint.
0011	DBGBVR<n>_EL1	Use for stepping T32 instructions.
1100	DBGBVR<n>_EL1+2	Use for stepping T32 instructions.
1111	DBGBVR<n>_EL1	Use for stepping A64 and A32 instructions.

For more information, see [Using the BAS field in Address Match breakpoints on page G2-4483](#).

For Context matching breakpoints, this field is RES1 and ignored.

If this field is implemented as an RW field, it resets to a value that is architecturally UNKNOWN.

Bits [4:3]

Reserved, RES0.

PMC, bits [2:1]

Privilege mode control. Determines the Exception level or levels at which a Breakpoint debug event for breakpoint n is generated. This field must be interpreted along with the SSC and HMC fields, and there are constraints on the permitted values of the {HMC, SSC, PMC} fields. For more information see the [DBGBCR<n>_EL1.SSC](#) description.

This field resets to a value that is architecturally UNKNOWN.

E, bit [0]

Enable breakpoint [DBGBVR<n>_EL1](#). Possible values are:

0 Breakpoint disabled.

1 Breakpoint enabled.

This field resets to a value that is architecturally UNKNOWN.

Accessing the DBGBCR<n>_EL1:

DBGBCR<n>_EL1 can be accessed through the external debug interface:

Component	Offset
Debug	0x408 + 16n

H9.2.3 DBGBVR<n>_EL1, Debug Breakpoint Value Registers, n = 0 - 15

The DBGBVR<n>_EL1 characteristics are:

Purpose

Holds a virtual address, or a VMID and/or a context ID, for use in breakpoint matching. Forms breakpoint n together with control register [DBGBCR<n>_EL1](#).

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	EDAD	SLK	Default
Error	Error	Error	Error	RO	RW

Configurations

External register DBGBVR<n>_EL1 is architecturally mapped to AArch64 System register [DBGBVR<n>_EL1](#).

External register DBGBVR<n>_EL1[31:0] is architecturally mapped to AArch32 System register [DBGBVR<n>](#).

If the breakpoint is context-aware and EL2 is implemented then External register [DBGBVR<n>_EL1](#) [63:32] is architecturally mapped to AArch32 System register [DBGBXVR<n>](#). Otherwise there is no External register access to [DBGBVR<n>_EL1](#)[63:32] from AArch32 state.

DBGBVR<n>_EL1 is in the Core power domain. RW fields in this register reset to architecturally UNKNOWN values. These apply only on a Cold reset. The register is not affected by a Warm reset and is not affected by an External debug reset.

If breakpoint n is not implemented then this register is unallocated.

Attributes

How this register is interpreted depends on the value of [DBGBCR<n>_EL1.BT](#).

- When [DBGBCR<n>_EL1.BT](#) is 0b0x0x, this register holds a virtual address.
- When [DBGBCR<n>_EL1.BT](#) is 0b001x, 0b011x, or 0b110x, this register holds a Context ID.
- When [DBGBCR<n>_EL1.BT](#) is 0b100x, this register holds a VMID.
- When [DBGBCR<n>_EL1.BT](#) is 0b101x, this register holds a VMID and a Context ID.
- When [DBGBCR<n>_EL1.BT](#) is 0b111x, this register holds two Context ID values.

For other values of [DBGBCR<n>_EL1.BT](#), this register is RES0.

Field descriptions

The DBGBVR<n>_EL1 bit assignments are:

When [DBGBCR<n>_EL1.BT](#)==0b0x0x:

RESS[14:4], bits [63:53]

Reserved, Sign extended. Software must treat this field as RES0 if the most significant bit of VA is 0 or RES0, and as RES1 if the most significant bit of VA is 1.

Hardware always ignores the value of these bits and it is IMPLEMENTATION DEFINED whether:

- The bits are hardwired to a copy of the most significant bit of VA, meaning writes to these bits are ignored, and reads to the bits always return the hardwired value.
- The value in those bits can be written, and reads will return the last value written. The value held in those bits is ignored by hardware.

VA[52:49], bits [52:49]

In ARMv8.2

Extension to VA[48:2]. See VA[48:2] for more details.

This field resets to a value that is architecturally UNKNOWN.

In ARMv8.1 and ARMv8.0.

Extension to RESS[14:4]. See RESS[14:4] for more details.

VA[48:2], bits [48:2]

If the address is being matched in an AArch64 stage 1 translation regime:

- This field contains bits[48:2] of the address for comparison.
- When [ARMv8.2-LVA](#) is implemented, and 52-bit addresses and a 64KB translation granule are in use, VA[52:49] form the upper part of the address value. Otherwise, VA[52:49] are RESS.

If the address is being matched in an AArch32 stage 1 translation regime, the first 20 bits of this field are RES0, and the rest of the field contains bits[31:2] of the address for comparison.

This field resets to a value that is architecturally UNKNOWN.

Bits [1:0]

Reserved, RES0.

When $DBGBCR\langle n \rangle_EL1.BT == 0b001x$:

Bits [63:32]

Reserved, RES0.

ContextID, bits [31:0]

Context ID value for comparison.

The value is compared against [CONTEXTIDR](#) and [CONTEXTIDR_EL1](#) in the following cases:

- The PE is in Secure state.
- EL2 is using AArch32.
- When [ARMv8.1-VHE](#) is not implemented.
- When [ARMv8.1-VHE](#) is implemented, [HCR_EL2.E2H](#) is 0 and the PE is in Non-secure EL0, EL1 or EL2.
- When [ARMv8.1-VHE](#) is implemented, [HCR_EL2](#).{E2H, TGE} is {1, 0} and the PE is in Non-secure EL0 or EL1.

When [ARMv8.1-VHE](#) is implemented, [HCR_EL2.E2H](#) is 1, the value is compared against [CONTEXTIDR_EL2](#) in the following cases:

- The PE is executing at EL2.
- [HCR_EL2.TGE](#) is 1 and the PE is in Non-secure EL0.

This field resets to a value that is architecturally UNKNOWN.

When [DBGBCR<n>_EL1.BT==0b011x](#):

Bits [63:32]

Reserved, RES0.

ContextID, bits [31:0]

Context ID value for comparison against [CONTEXTIDR_EL1](#).

This field resets to a value that is architecturally UNKNOWN.

When [DBGBCR<n>_EL1.BT==0b100x](#) and [EL2](#) implemented:

Bits [63:48]

Reserved, RES0.

VMID[15:8], bits [47:40]

In [ARMv8.2](#) and [ARMv8.1](#)

Extension to [VMID\[7:0\]](#). See [VMID\[7:0\]](#) for more details.

This field resets to a value that is architecturally UNKNOWN.

In [ARMv8.0](#).

Reserved, RES0.

VMID[7:0], bits [39:32]

VMID value for comparison.

The VMID is 8 bits in the following cases.

- [EL2](#) is using [AArch32](#).
- [ARMv8.1-VMID16](#) is not implemented.

When [ARMv8.1-VMID16](#) is implemented and [EL2](#) is using [AArch64](#), it is IMPLEMENTATION DEFINED whether the VMID is 8 bits or 16 bits.

[VMID\[15:8\]](#) is RES0 if any of the following applies:

- The implementation has an 8-bit VMID.
- [VTCR_EL2.VS](#) has a value of 0.
- [EL2](#) is using [AArch32](#).

This field resets to a value that is architecturally UNKNOWN.

Bits [31:0]

Reserved, RES0.

When $DBGBCR<n>_EL1.BT==0b101x$ and EL2 implemented:

Bits [63:48]

Reserved, RES0.

VMID[15:8], bits [47:40]

In ARMv8.2 and ARMv8.1

Extension to VMID[7:0]. See VMID[7:0] for more details.

This field resets to a value that is architecturally UNKNOWN.

In ARMv8.0.

Reserved, RES0.

VMID[7:0], bits [39:32]

VMID value for comparison.

The VMID is 8 bits in the following cases.

- EL2 is using AArch32.
- [ARMv8.1-VMID16](#) is not implemented.

When [ARMv8.1-VMID16](#) is implemented and EL2 is using AArch64, it is IMPLEMENTATION DEFINED whether the VMID is 8 bits or 16 bits.

VMID[15:8] is RES0 if any of the following applies:

- The implementation has an 8-bit VMID.
- [VTCR_EL2.VS](#) has a value of 0.
- EL2 is using AArch32.

This field resets to a value that is architecturally UNKNOWN.

ContextID, bits [31:0]

Context ID value for comparison against [CONTEXTIDR_EL1](#).

This field resets to a value that is architecturally UNKNOWN.

When $DBGBCR<n>_EL1.BT==0b110x$ and EL2 implemented:

ContextID2, bits [63:32]

Context ID value for comparison against [CONTEXTIDR_EL2](#).

This field resets to a value that is architecturally UNKNOWN.

Bits [31:0]

Reserved, RES0.

When $DBGBCR\langle n \rangle_EL1.BT=0b111x$ and EL2 implemented:

ContextID2, bits [63:32]

Context ID value for comparison against `CONTEXTIDR_EL2`.
This field resets to a value that is architecturally UNKNOWN.

ContextID, bits [31:0]

Context ID value for comparison against `CONTEXTIDR_EL1`.
This field resets to a value that is architecturally UNKNOWN.

Accessing the $DBGBVR\langle n \rangle_EL1$:

`DBGBVR<n>_EL1[31:0]` can be accessed through the external debug interface:

Component	Offset
Debug	$0x400 + 16n$

`DBGBVR<n>_EL1[63:32]` can be accessed through the external debug interface:

Component	Offset
Debug	$0x404 + 16n$

H9.2.4 DBGCLAIMCLR_EL1, Debug Claim Tag Clear register

The DBGCLAIMCLR_EL1 characteristics are:

Purpose

Used by software to read the values of the CLAIM tag bits, and to clear these bits to 0.
The architecture does not define any functionality for the CLAIM tag bits.

———— Note —————

CLAIM tags are typically used for communication between the debugger and target software.

Used in conjunction with the [DBGCLAIMSET_EL1](#) register.

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	SLK	Default
Error	Error	Error	RO	RW

Configurations

External register DBGCLAIMCLR_EL1 is architecturally mapped to AArch64 System register [DBGCLAIMCLR_EL1](#).

External register DBGCLAIMCLR_EL1 is architecturally mapped to AArch32 System register [DBGCLAIMCLR](#).

DBGCLAIMCLR_EL1 is in the Core power domain.

See the CLAIM field description for the effect of a Cold reset on the value returned by this register. This register is not affected by a Warm reset, and is not affected by an External debug reset.

An implementation must include 8 CLAIM tag bits.

Attributes

DBGCLAIMCLR_EL1 is a 32-bit register.

Field descriptions

The DBGCLAIMCLR_EL1 bit assignments are:

Bits [31:8]

Reserved, RAZ/SBZ. Software can rely on these bits reading as zero, and must use a should-be-zero policy on writes. Implementations must ignore writes.

CLAIM, bits [7:0]

Read or clear CLAIM tag bits. Reading this field returns the current value of the CLAIM tag bits.

Writing a 1 to one of these bits clears the corresponding CLAIM tag bit to 0. This is an indirect write to the CLAIM tag bits. A single write operation can clear multiple CLAIM tag bits to 0.

Writing 0 to one of these bits has no effect.

A cold reset clears the CLAIM tag bits to 0.

Accessing the DBGCLAIMCLR_EL1:

DBGCLAIMCLR_EL1 can be accessed through the external debug interface:

Component	Offset
Debug	0xFA4

H9.2.5 DBGCLAIMSET_EL1, Debug Claim Tag Set register

The DBGCLAIMSET_EL1 characteristics are:

Purpose

Used by software to set the CLAIM tag bits to 1.

The architecture does not define any functionality for the CLAIM tag bits.

———— Note —————

CLAIM tags are typically used for communication between the debugger and target software.

Used in conjunction with the [DBGCLAIMCLR_EL1](#) register.

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	SLK	Default
Error	Error	Error	RO	RW

Configurations

External register DBGCLAIMSET_EL1 is architecturally mapped to AArch64 System register [DBGCLAIMSET_EL1](#).

External register DBGCLAIMSET_EL1 is architecturally mapped to AArch32 System register [DBGCLAIMSET](#).

DBGCLAIMSET_EL1 is in the Core power domain.

An implementation must include 8 CLAIM tag bits.

Attributes

DBGCLAIMSET_EL1 is a 32-bit register.

Field descriptions

The DBGCLAIMSET_EL1 bit assignments are:

Bits [31:8]

Reserved, RAZ/SBZ. Software can rely on these bits reading as zero, and must use a should-be-zero policy on writes. Implementations must ignore writes.

CLAIM, bits [7:0]

Set CLAIM tag bits. RAO.

Writing a 1 to one of these bits sets the corresponding CLAIM tag bit to 1. This is an indirect write to the CLAIM tag bits. A single write operation can set multiple CLAIM tag bits to 1.

Writing 0 to one of these bits has no effect.

A cold reset clears the CLAIM tag bits to 0.

Accessing the DBGCLAIMSET_EL1:

DBGCLAIMSET_EL1 can be accessed through the external debug interface:

Component	Offset
Debug	0xFA0

H9.2.6 DBGDTRRX_EL0, Debug Data Transfer Register, Receive

The DBGDTRRX_EL0 characteristics are:

Purpose

Transfers data from an external debugger to the PE. For example, it is used by a debugger transferring commands and data to a debug target. It is a component of the Debug Communications Channel.

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	SLK	Default
Error	Error	Error	RO	RW

If `EDSCR.ITE == 0` when the PE exits Debug state on receiving a Restart request trigger event, the behavior of any operation issued by a DTR access in memory access mode that has not completed execution is `CONSTRAINED UNPREDICTABLE`, and must do one of the following:

- It must complete execution in Debug state before the PE executes the restart sequence.
- It must complete execution in Non-debug state before the PE executes the restart sequence.
- It must be abandoned. This means that the instruction does not execute. Any registers or memory accessed by the instruction are left in an `UNKNOWN` state.

Configurations

External register DBGDTRRX_EL0 is architecturally mapped to AArch64 System register [DBGDTRRX_EL0](#).

External register DBGDTRRX_EL0 is architecturally mapped to AArch32 System register [DBGDTRRXint](#).

DBGDTRRX_EL0 is in the Core power domain. RW fields in this register reset to architecturally `UNKNOWN` values. These apply only on a Cold reset. The register is not affected by a Warm reset and is not affected by an External debug reset.

Attributes

DBGDTRRX_EL0 is a 32-bit register.

Field descriptions

The DBGDTRRX_EL0 bit assignments are:

Bits [31:0]

Update DTRRX.

If `RXfull` is set to 0, then writes to this register update the value in `DTRRX` and set `RXfull` to 1.

Reads of this register return the last value written to `DTRRX` and do not change `RXfull`.

For the full behavior of the Debug Communications Channel, see [Chapter H4 The Debug Communication Channel and Instruction Transfer Register](#).

This field resets to a value that is architecturally `UNKNOWN`.

Accessing the DBGDTRRX_EL0:

DBGDTRRX_EL0 can be accessed through the external debug interface:

Component	Offset
Debug	0x080

H9.2.7 DBGDTRTX_EL0, Debug Data Transfer Register, Transmit

The DBGDTRTX_EL0 characteristics are:

Purpose

Transfers data from the PE to an external debugger. For example, it is used by a debug target to transfer data to the debugger. It is a component of the Debug Communication Channel.

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	SLK	Default
Error	Error	Error	RO	RW

If `EDSCR.ITE == 0` when the PE exits Debug state on receiving a Restart request trigger event, the behavior of any operation issued by a DTR access in memory access mode that has not completed execution is `CONSTRAINED UNPREDICTABLE`, and must do one of the following:

- It must complete execution in Debug state before the PE executes the restart sequence.
- It must complete execution in Non-debug state before the PE executes the restart sequence.
- It must be abandoned. This means that the instruction does not execute. Any registers or memory accessed by the instruction are left in an `UNKNOWN` state.

Configurations

External register DBGDTRTX_EL0 is architecturally mapped to AArch64 System register [DBGDTRTX_EL0](#).

External register DBGDTRTX_EL0 is architecturally mapped to AArch32 System register [DBGDTRTXint](#).

DBGDTRTX_EL0 is in the Core power domain. RW fields in this register reset to architecturally `UNKNOWN` values. These apply only on a Cold reset. The register is not affected by a Warm reset and is not affected by an External debug reset.

Attributes

DBGDTRTX_EL0 is a 32-bit register.

Field descriptions

The DBGDTRTX_EL0 bit assignments are:

Bits [31:0]

Return DTRTX.

If `TXfull` is set to 1, then reads of this register return the value in `DTRTX` and clear `TXfull` to 0.

Writes of this register update the value in `DTRTX` and do not change `TXfull`.

For the full behavior of the Debug Communications Channel, see [Chapter H4 The Debug Communication Channel and Instruction Transfer Register](#).

This field resets to a value that is architecturally `UNKNOWN`.

Accessing the DBGDTRTX_EL0:

DBGDTRTX_EL0 can be accessed through the external debug interface:

Component	Offset
Debug	0x08C

H9.2.8 DBGWCR<n>_EL1, Debug Watchpoint Control Registers, n = 0 - 15

The DBGWCR<n>_EL1 characteristics are:

Purpose

Holds control information for a watchpoint. Forms watchpoint n together with value register [DBGWVR<n>_EL1](#).

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	EDAD	SLK	Default
Error	Error	Error	Error	RO	RW

Configurations

External register DBGWCR<n>_EL1 is architecturally mapped to AArch64 System register [DBGWCR<n>_EL1](#).

External register DBGWCR<n>_EL1 is architecturally mapped to AArch32 System register [DBGWCR<n>](#).

DBGWCR<n>_EL1 is in the Core power domain. RW fields in this register reset to architecturally UNKNOWN values. These apply only on a Cold reset. The register is not affected by a Warm reset and is not affected by an External debug reset.

If breakpoint n is not implemented then this register is unallocated.

Attributes

DBGWCR<n>_EL1 is a 32-bit register.

Field descriptions

The DBGWCR<n>_EL1 bit assignments are:

When the E field is zero, all the other fields in the register are ignored.

Bits [31:29]

Reserved, RES0.

MASK, bits [28:24]

Address mask. Only objects up to 2GB can be watched using a single mask.

- 00000 No mask.
- 00001 Reserved.
- 00010 Reserved.

If programmed with a reserved value, a watchpoint must behave as if either:

- MASK has been programmed with a defined value, which might be 0 (no mask), other than for a direct read of DBGWCRn_EL1.
- The watchpoint is disabled.

Software must not rely on this property because the behavior of reserved values might change in a future revision of the architecture.

Other values mask the corresponding number of address bits, from 0b00011 masking 3 address bits (0x0000007 mask for address) to 0b11111 masking 31 address bits (0x7FFFFFFF mask for address).

This field resets to a value that is architecturally UNKNOWN.

Bits [23:21]

Reserved, RES0.

WT, bit [20]

Watchpoint type. Possible values are:

- 0 Unlinked data address match.
- 1 Linked data address match.

This field resets to a value that is architecturally UNKNOWN.

LBN, bits [19:16]

Linked breakpoint number. For Linked data address watchpoints, this specifies the index of the Context-matching breakpoint linked to.

This field resets to a value that is architecturally UNKNOWN.

SSC, bits [15:14]

Security state control. Determines the Security states under which a Watchpoint debug event for watchpoint n is generated. This field must be interpreted along with the HMC and PAC fields.

This field resets to a value that is architecturally UNKNOWN.

HMC, bit [13]

Higher mode control. Determines the debug perspective for deciding when a Watchpoint debug event for watchpoint n is generated. This field must be interpreted along with the SSC and PAC fields.

This field resets to a value that is architecturally UNKNOWN.

BAS, bits [12:5]

Byte address select. Each bit of this field selects whether a byte from within the word or double-word addressed by `DBGWVR<n>_EL1` is being watched.

BAS	Description
xxxxxx1	Match byte at <code>DBGWVR<n>_EL1</code>
xxxxxx1x	Match byte at <code>DBGWVR<n>_EL1+1</code>
xxxxxx1xx	Match byte at <code>DBGWVR<n>_EL1+2</code>
xxxxxx1xxx	Match byte at <code>DBGWVR<n>_EL1+3</code>

In cases where `DBGWVR<n>_EL1` addresses a double-word:

BAS	Description, if <code>DBGWVR<n>_EL1[2] == 0</code>
xxx1xxxx	Match byte at <code>DBGWVR<n>_EL1+4</code>
xx1xxxxx	Match byte at <code>DBGWVR<n>_EL1+5</code>
x1xxxxxx	Match byte at <code>DBGWVR<n>_EL1+6</code>
1xxxxxxx	Match byte at <code>DBGWVR<n>_EL1+7</code>

If `DBGWVR<n>_EL1[2] == 1`, only `BAS[3:0]` is used. ARM deprecates setting `DBGWVR<n>_EL1[2] == 1`.

The valid values for `BAS` are non-zero binary number all of whose set bits are contiguous. All other values are reserved and must not be used by software. See *Reserved `DBGWCR<n>.BAS` values on page G2-4507*.

This field resets to a value that is architecturally UNKNOWN.

LSC, bits [4:3]

Load/store control. This field enables watchpoint matching on the type of access being made. Possible values of this field are:

- 01 Match instructions that load from a watchpointed address.
- 10 Match instructions that store to a watchpointed address.
- 11 Match instructions that load from or store to a watchpointed address.

All other values are reserved, but must behave as if the watchpoint is disabled. Software must not rely on this property as the behavior of reserved values might change in a future revision of the architecture.

This field resets to a value that is architecturally UNKNOWN.

PAC, bits [2:1]

Privilege of access control. Determines the Exception level or levels at which a Watchpoint debug event for watchpoint `n` is generated. This field must be interpreted along with the `SSC` and `HMC` fields.

This field resets to a value that is architecturally UNKNOWN.

E, bit [0]

Enable watchpoint `n`. Possible values are:

- 0 Watchpoint disabled.
- 1 Watchpoint enabled.

This field resets to a value that is architecturally UNKNOWN.

Accessing the `DBGWCR<n>_EL1`:

`DBGWCR<n>_EL1` can be accessed through the external debug interface:

Component	Offset
Debug	$0x808 + 16n$

H9.2.9 DBGWVR<n>_EL1, Debug Watchpoint Value Registers, n = 0 - 15

The DBGWVR<n>_EL1 characteristics are:

Purpose

Holds a data address value for use in watchpoint matching. Forms watchpoint n together with control register [DBGWCR<n>_EL1](#).

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	EDAD	SLK	Default
Error	Error	Error	Error	RO	RW

Configurations

External register DBGWVR<n>_EL1 is architecturally mapped to AArch64 System register [DBGWVR<n>_EL1](#).

External register DBGWVR<n>_EL1[31:0] is architecturally mapped to AArch32 System register [DBGWVR<n>](#).

DBGWVR<n>_EL1 is in the Core power domain. RW fields in this register reset to architecturally UNKNOWN values. These apply only on a Cold reset. The register is not affected by a Warm reset and is not affected by an External debug reset.

If breakpoint n is not implemented then this register is unallocated.

Attributes

DBGWVR<n>_EL1 is a 64-bit register.

Field descriptions

The DBGWVR<n>_EL1 bit assignments are:

RESS[14:4], bits [63:53]

Reserved, Sign extended. Hardware and software must treat this field as RES0 if the most significant bit of VA is 0 or RES0, and as RES1 if the most significant bit of VA is 1.

Hardware always ignores the value of these bits and it is IMPLEMENTATION DEFINED whether:

- The bits are hardwired to a copy of the most significant bit of VA, meaning writes to these bits are ignored, and reads to the bits always return the hardwired value.
- The value in those bits can be written, and reads will return the last value written. The value held in those bits is ignored by hardware.

VA[52:49], bits [52:49]

In ARMv8.2

Extension to VA[48:2]. See VA[48:2] for more details.

This field resets to a value that is architecturally UNKNOWN.

In ARMv8.1 and ARMv8.0.

Extension to RESS[14:4]. See RESS[14:4] for more details.

VA[48:2], bits [48:2]

Bits[48:2] of the address value for comparison.

When [ARMv8.2-LVA](#) is implemented, and 52-bit addresses and a 64KB translation granule are in use, VA[52:49] forms the upper part of the address value. Otherwise, VA[52:49] are RESS.

ARM deprecates setting `DBGWVR<n>_EL1[2] == 1`.

This field resets to a value that is architecturally UNKNOWN.

Bits [1:0]

Reserved, RES0.

Accessing the `DBGWVR<n>_EL1`:

`DBGWVR<n>_EL1[31:0]` can be accessed through the external debug interface:

Component	Offset
Debug	$0x800 + 16n$

`DBGWVR<n>_EL1[63:32]` can be accessed through the external debug interface:

Component	Offset
Debug	$0x804 + 16n$

H9.2.10 EDAA32PFR, External Debug AArch32 Processor Feature Register

The EDAA32PFR characteristics are:

Purpose

Provides information about implemented PE features.

For general information about the interpretation of the ID registers see [Principles of the ID scheme for fields in ID registers on page D7-2195](#).

Usage constraints

This register is accessible as follows:

Off	DLK	Default
IMP DEF	IMP DEF	RO

Configurations

It is IMPLEMENTATION DEFINED whether EDAA32PFR is implemented in the Core power domain or in the Debug power domain.

EDAA32PFR is only accessible in an implementation that only supports execution in AA32 state. If AArch64 state is supported at any Exception level, EDAA32PFR is RES0.

Attributes

EDAA32PFR is a 64-bit register.

Field descriptions

The EDAA32PFR bit assignments are:

Bits [63:16]

Reserved, RES0.

EL3, bits [15:12]

AArch32 EL3 Exception level handling. Defined values are:

0000 EL3 is not implemented.

0001 EL3 can be executed in AArch32 state only.

When the value of [EDPFR.EL3](#) is non-zero, this field must be 0000.

All other values are reserved.

————— **Note** —————

[EDPFR](#).{EL1, EL0} indicate whether EL1 and EL0 can only be executed in AArch32 state.

EL2, bits [11:8]

AArch32 EL2 Exception level handling. Defined values are:

0000 EL2 is not implemented.

0001 EL2 can be executed in AArch32 state only.

When the value of [EDPFR.EL2](#) is non-zero, this field must be 0000.

All other values are reserved.

Note

EDPFR.{EL1, EL0} indicate whether EL1 and EL0 can only be executed in AArch32 state.

PMSA, bits [7:4]

Indicates support for a PMSA. Defined values are:

0000 PMSA not supported.

0100 Support for an ARMv8-R PMSAv8-32.

All other values are reserved. In ARMv8-A, the only permitted value is 0000.

VMSA, bits [3:0]

Indicates support for a VMSA. When the PMSA field is nonzero, determines support for a VMSA. When the PMSA field is 0000, VMSA is supported. Defined values are:

0000 VMSA not supported.

All other values are reserved. In ARMv8-A, the only permitted value is 0000.

Accessing the EDAA32PFR:

EDAA32PFR can be accessed through the external debug interface:

Component	Offset
Debug	0xD60

H9.2.11 EDACR, External Debug Auxiliary Control Register

The EDACR characteristics are:

Purpose

Allows implementations to support IMPLEMENTATION DEFINED controls.

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	SLK	Default
IMP DEF	IMP DEF	IMP DEF	RO	RW

Configurations

It is IMPLEMENTATION DEFINED whether EDACR is implemented in the Core power domain or in the Debug power domain. RW fields in this register reset to architecturally UNKNOWN values, and:

- The register is not affected by a Warm reset.
- If the register is implemented in the Core power domain the reset values apply on a Cold reset, and the register is not affected by an External debug reset.
- If the register is implemented in the Debug power domain the reset values apply on an External debug reset, and the register is not affected by a Cold reset.

Changing this register from its reset value causes IMPLEMENTATION DEFINED behavior, including possible deviation from the architecturally-defined behavior.

If the EDACR contains any control bits that must be preserved over power down, then these bits must be accessible by the external debug interface when `OSLSR_EL1.OSLK == 1` (OS lock is locked) and when the Core is powered off.

Attributes

EDACR is a 32-bit register.

Field descriptions

The EDACR bit assignments are:

IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

This field resets to a value that is architecturally UNKNOWN.

Accessing the EDACR:

EDACR can be accessed through the external debug interface:

Component	Offset
Debug	0x094

H9.2.12 EDCIDR0, External Debug Component Identification Register 0

The EDCIDR0 characteristics are:

Purpose

Provides information to identify an external debug component.

For more information see [About the Component Identification scheme on page K2-6149](#).

Usage constraints

This register is accessible as follows:

Default

RO

Configurations

EDCIDR0 is in the Debug power domain.

Implementation of this register is OPTIONAL.

This register is required for CoreSight compliance.

Attributes

EDCIDR0 is a 32-bit register.

Field descriptions

The EDCIDR0 bit assignments are:

Bits [31:8]

Reserved, RES0.

PRMBL_0, bits [7:0]

Preamble. Must read as 0x0D.

Accessing the EDCIDR0:

EDCIDR0 can be accessed through the external debug interface:

Component	Offset
-----------	--------

Debug	0xFF0
-------	-------

H9.2.13 EDCIDR1, External Debug Component Identification Register 1

The EDCIDR1 characteristics are:

Purpose

Provides information to identify an external debug component.

For more information see [About the Component Identification scheme on page K2-6149](#).

Usage constraints

This register is accessible as follows:

Default

RO

Configurations

EDCIDR1 is in the Debug power domain.

Implementation of this register is OPTIONAL.

This register is required for CoreSight compliance.

Attributes

EDCIDR1 is a 32-bit register.

Field descriptions

The EDCIDR1 bit assignments are:

Bits [31:8]

Reserved, RES0.

CLASS, bits [7:4]

Component class. Reads as 0x9, debug component.

PRMBL_1, bits [3:0]

Preamble. RAZ.

Accessing the EDCIDR1:

EDCIDR1 can be accessed through the external debug interface:

Component	Offset
------------------	---------------

Debug	0xFF4
-------	-------

H9.2.14 EDCIDR2, External Debug Component Identification Register 2

The EDCIDR2 characteristics are:

Purpose

Provides information to identify an external debug component.

For more information see [About the Component Identification scheme on page K2-6149](#).

Usage constraints

This register is accessible as follows:

Default

RO

Configurations

EDCIDR2 is in the Debug power domain.

Implementation of this register is OPTIONAL.

This register is required for CoreSight compliance.

Attributes

EDCIDR2 is a 32-bit register.

Field descriptions

The EDCIDR2 bit assignments are:

Bits [31:8]

Reserved, RES0.

PRMBL_2, bits [7:0]

Preamble. Must read as 0x05.

Accessing the EDCIDR2:

EDCIDR2 can be accessed through the external debug interface:

Component	Offset
-----------	--------

Debug	0xFF8
-------	-------

H9.2.15 EDCIDR3, External Debug Component Identification Register 3

The EDCIDR3 characteristics are:

Purpose

Provides information to identify an external debug component.

For more information see [About the Component Identification scheme on page K2-6149](#).

Usage constraints

This register is accessible as follows:

Default

RO

Configurations

EDCIDR3 is in the Debug power domain.

Implementation of this register is OPTIONAL.

This register is required for CoreSight compliance.

Attributes

EDCIDR3 is a 32-bit register.

Field descriptions

The EDCIDR3 bit assignments are:

Bits [31:8]

Reserved, RES0.

PRMBL_3, bits [7:0]

Preamble. Must read as 0xB1.

Accessing the EDCIDR3:

EDCIDR3 can be accessed through the external debug interface:

Component	Offset
------------------	---------------

Debug	0xFFC
-------	-------

H9.2.16 EDCIDSR, External Debug Context ID Sample Register

The EDCIDSR characteristics are:

Purpose

Contains the sampled value of the Context ID, captured on reading [EDPCSR](#)[31:0].

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	Default
Error	Error	Error	RO

Configurations

EDCIDSR is in the Core power domain.

Fields in this register reset to architecturally UNKNOWN values. These apply only on a Cold reset. The register is not affected by a Warm reset and is not affected by an External debug reset.

Implemented only if the OPTIONAL PC Sample-based Profiling Extension is implemented but not with [ARMv8.2-PCSample](#). If [ARMv8.2-PCSample](#) is implemented, this register is RES0 and the architecture defines the functionality in [PMCID1SR](#) and [PMCID2SR](#).

Attributes

EDCIDSR is a 32-bit register.

Field descriptions

The EDCIDSR bit assignments are:

When ARMv8.2-PCSample is not implemented:

CONTEXTIDR, bits [31:0]

Context ID. The value of [CONTEXTIDR](#) that is associated with the most recent [EDPCSR](#) sample.

- If EL1 is using AArch64, then the Context ID is held in [CONTEXTIDR_EL1](#).
- If EL1 is using AArch32, then the Context ID is held in [CONTEXTIDR](#).
- If EL3 is implemented and is using AArch32, then [CONTEXTIDR](#) is a banked register, and EDCIDSR samples the current banked copy of [CONTEXTIDR](#) for the Security state that is associated with the most recent [EDPCSR](#) sample.

Because the value written to EDCIDSR is an indirect read of [CONTEXTIDR](#), therefore it is CONSTRAINED UNPREDICTABLE whether EDCIDSR is set to the original or new value if a read of [EDPCSR](#)_{lo} samples:

- An instruction that writes to [CONTEXTIDR_EL1](#).
- The next Context synchronization event.
- Any instruction executed between these two instructions.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

When ARMv8.2-PCSample is implemented:

Bits [31:0]

Reserved, RES0.

Accessing the EDCIDSR:

EDCIDSR can be accessed through the external debug interface:

Component	Offset
Debug	0x0A4

H9.2.17 EDDEVAFF0, External Debug Device Affinity register 0

The EDDEVAFF0 characteristics are:

Purpose

Copy of the low half of the PE [MPIDR_EL1](#) register that allows a debugger to determine which PE in a multiprocessor system the external debug component relates to.

Usage constraints

This register is accessible as follows:

Default
RO

Configurations

EDDEVAFF0 is in the Debug power domain.

Implementation of this register is OPTIONAL.

Attributes

EDDEVAFF0 is a 32-bit register.

Field descriptions

The EDDEVAFF0 bit assignments are:

Bits [31:0]

[MPIDR_EL1](#) low half. Read-only copy of the low half of [MPIDR_EL1](#), as seen from the highest implemented Exception level.

Accessing the EDDEVAFF0:

EDDEVAFF0 can be accessed through the external debug interface:

Component	Offset
Debug	0xFA8

H9.2.18 EDDEVAFF1, External Debug Device Affinity register 1

The EDDEVAFF1 characteristics are:

Purpose

Copy of the high half of the PE [MPIDR_EL1](#) register that allows a debugger to determine which PE in a multiprocessor system the external debug component relates to.

Usage constraints

This register is accessible as follows:

Default

RO

Configurations

EDDEVAFF1 is in the Debug power domain.

Implementation of this register is OPTIONAL.

Attributes

EDDEVAFF1 is a 32-bit register.

Field descriptions

The EDDEVAFF1 bit assignments are:

Bits [31:0]

[MPIDR_EL1](#) high half. Read-only copy of the high half of [MPIDR_EL1](#), as seen from the highest implemented Exception level.

Accessing the EDDEVAFF1:

EDDEVAFF1 can be accessed through the external debug interface:

Component	Offset
-----------	--------

Debug	0xFAC
-------	-------

H9.2.19 EDDEVARCH, External Debug Device Architecture register

The EDDEVARCH characteristics are:

Purpose

Identifies the programmers' model architecture of the external debug component.

Usage constraints

This register is accessible as follows:

Default

RO

Configurations

EDDEVARCH is in the Debug power domain.

Implementation of this register is OPTIONAL.

Attributes

EDDEVARCH is a 32-bit register.

Field descriptions

The EDDEVARCH bit assignments are:

ARCHITECT, bits [31:21]

Defines the architecture of the component. For debug, this is ARM Limited.

Bits [31:28] are the JEP106 continuation code, 0x4.

Bits [27:21] are the JEP106 ID code, 0x3B.

PRESENT, bit [20]

When set to 1, indicates that the DEVARCH is present.

This field is 1 in ARMv8.

REVISION, bits [19:16]

Defines the architecture revision. For architectures defined by ARM this is the minor revision.

For debug, the revision defined by ARMv8 is 0x0.

All other values are reserved.

ARCHID, bits [15:0]

Defines this part to be an ARMv8 debug component. For architectures defined by ARM this is further subdivided.

For debug:

- Bits [15:12] are the architecture version.
 - In an ARMv8.0 implementation, the only permitted value is 0x6.

- In an ARMv8.1 implementation that includes [ARMv8.1-VHE](#), the only permitted value is 0x7.
- In an ARMv8.1 implementation that does not include [ARMv8.1-VHE](#), the permitted values are 0x6 and 0x7.
- In an ARMv8.2 implementation, the only permitted value is 0x8.
- Bits [11:0] are the architecture part number, 0xA15.

This corresponds to the ARMv8 debug architecture version.

Accessing the EDDEVARCH:

EDDEVARCH can be accessed through the external debug interface:

Component	Offset
Debug	0xFBC

H9.2.20 EDDEVID, External Debug Device ID register 0

The EDDEVID characteristics are:

Purpose

Provides extra information for external debuggers about features of the debug implementation.

Usage constraints

This register is accessible as follows:

Default

RO

Configurations

EDDEVID is in the Debug power domain.

Attributes

EDDEVID is a 32-bit register.

Field descriptions

The EDDEVID bit assignments are:

31	28 27	24 23	4 3	0
RES0	AuxRegs	RES0	PCSample	

Bits [31:28]

Reserved, RES0.

AuxRegs, bits [27:24]

Indicates support for Auxiliary registers. Permitted values for this field are:

0000 None supported.

0001 Support for External Debug Auxiliary Control Register, [EDACR](#).

All other values are reserved.

Bits [23:4]

Reserved, RES0.

PCSample, bits [3:0]

Indicates the level of PC Sample-based Profiling support using external debug registers. Permitted values of this field are:

0000 Architecture-defined form of PC Sample-based Profiling not implemented using external debug registers.

0010 Only [EDPCSR](#) and [EDCIDSR](#) are implemented. This option is only permitted if EL3 and EL2 are not implemented.

0011 [EDPCSR](#), [EDCIDSR](#), and [EDVIDSR](#) are implemented.

All other values are reserved.

From ARMv8.2 onwards, the only permitted value is 0b0000. The architecture defines the functionality in a different set of registers, see [PMDEVID](#).

Accessing the EDDEVID:

EDDEVID can be accessed through the external debug interface:

Component	Offset
Debug	0xFC8

H9.2.21 EDDEVID1, External Debug Device ID register 1

The EDDEVID1 characteristics are:

Purpose

Provides extra information for external debuggers about features of the debug implementation.

Usage constraints

This register is accessible as follows:

Default

RO

Configurations

EDDEVID1 is in the Debug power domain.

Attributes

EDDEVID1 is a 32-bit register.

Field descriptions

The EDDEVID1 bit assignments are:

Bits [31:4]

Reserved, RES0.

PCSROffset, bits [3:0]

This field indicates the offset applied to PC samples returned by reads of [EDPCSR](#). Permitted values of this field in ARMv8 are:

0000 [EDPCSR](#) not implemented.

0010 [EDPCSR](#) implemented, and samples have no offset applied and do not sample the instruction set state in AArch32 state.

From ARMv8.2 onwards, the only permitted value is 0b0000. The architecture defines the functionality in a different set of registers, see [PMDEVID](#).

Accessing the EDDEVID1:

EDDEVID1 can be accessed through the external debug interface:

Component	Offset
Debug	0xFC4

H9.2.22 EDDEVID2, External Debug Device ID register 2

The EDDEVID2 characteristics are:

Purpose

Reserved for future descriptions of features of the debug implementation.

Usage constraints

This register is accessible as follows:

Default

RO

Configurations

EDDEVID2 is in the Debug power domain.

Attributes

EDDEVID2 is a 32-bit register.

Field descriptions

The EDDEVID2 bit assignments are:

Bits [31:0]

Reserved, RES0.

Accessing the EDDEVID2:

EDDEVID2 can be accessed through the external debug interface:

Component	Offset
Debug	0xFC0

H9.2.23 EDDEVTYPE, External Debug Device Type register

The EDDEVTYPE characteristics are:

Purpose

Indicates to a debugger that this component is part of a PE's debug logic.

Usage constraints

This register is accessible as follows:

Default

RO

Configurations

EDDEVTYPE is in the Debug power domain.

Implementation of this register is OPTIONAL.

Attributes

EDDEVTYPE is a 32-bit register.

Field descriptions

The EDDEVTYPE bit assignments are:

Bits [31:8]

Reserved, RES0.

SUB, bits [7:4]

Subtype. Must read as 0x1 to indicate this is a component within a PE.

MAJOR, bits [3:0]

Major type. Must read as 0x5 to indicate this is a debug logic component.

Accessing the EDDEVTYPE:

EDDEVTYPE can be accessed through the external debug interface:

Component	Offset
Debug	0xFCC

H9.2.24 EDDFR, External Debug Feature Register

The EDDFR characteristics are:

Purpose

Provides top level information about the debug system.

Note

Debuggers must use [EDDEVARCH](#) to determine the Debug architecture version.

For general information about the interpretation of the ID registers see [Principles of the ID scheme for fields in ID registers on page D7-2195](#).

Usage constraints

This register is accessible as follows:

Off	DLK	Default
IMP DEF	IMP DEF	RO

Configurations

It is IMPLEMENTATION DEFINED whether EDDFR is implemented in the Core power domain or in the Debug power domain.

Attributes

EDDFR is a 64-bit register.

Field descriptions

The EDDFR bit assignments are:

Bits [63:32]

Reserved, RES0.

CTX_CMPs, bits [31:28]

Number of breakpoints that are context-aware, minus 1. These are the highest numbered breakpoints.

In an ARMv8-A implementation that supports AArch64 state in at least one Exception level, this field returns the value of [ID_AA64DFR0_EL1.CTX_CMPs](#).

Bits [27:24]

Reserved, RES0.

WRPs, bits [23:20]

Number of watchpoints, minus 1. The value of 0b0000 is reserved.

In an ARMv8-A implementation that supports AArch64 state in at least one Exception level, this field returns the value of [ID_AA64DFR0_EL1.WRPs](#).

Bits [19:16]

Reserved, RES0.

BRPs, bits [15:12]

Number of breakpoints, minus 1. The value of 0b0000 is reserved.

In an ARMv8-A implementation that supports AArch64 state in at least one Exception level, this field returns the value of [ID_AA64DFR0_EL1](#).BRPs.

PMUVer, bits [11:8]

Performance Monitors Extension version. Indicates whether System register interface to Performance Monitors extension is implemented. Defined values are:

- 0000 Performance Monitors Extension System registers not implemented.
- 0001 Performance Monitors Extension System registers implemented, PMUv3.
- 0100 Performance Monitors Extension System registers implemented, PMUv3, with a 16-bit evtCount field, and if EL2 is implemented, the addition of the MDCR_EL2.HPMD bit.
- 1111 IMPLEMENTATION DEFINED form of performance monitors supported, PMUv3 not supported.

All other values are reserved.

In ARMv8.0 the permitted values are 0b0000, 0b0001 and 0b1111.

From ARMv8.1 the permitted values are 0b0000, 0b0100 and 0b1111.

In an ARMv8-A implementation that supports AArch64 state in at least one Exception level, this field returns the value of [ID_AA64DFR0_EL1](#).PMUVer.

TraceVer, bits [7:4]

Trace support. Indicates whether System register interface to a trace macrocell is implemented. Defined values are:

- 0000 Trace macrocell System registers not implemented.
- 0001 Trace macrocell System registers implemented.

All other values are reserved.

A value of 0b0000 only indicates that no System register interface to a trace macrocell is implemented. A trace macrocell might nevertheless be implemented without a System register interface.

In an ARMv8-A implementation that supports AArch64 state in at least one Exception level, this field returns the value of [ID_AA64DFR0_EL1](#).TraceVer.

UNKNOWN, bits [3:0]

Reserved, UNKNOWN.

Accessing the EDDFR:

EDDFR[31:0] can be accessed through the external debug interface:

Component	Offset
Debug	0xD28

EDDFR[63:32] can be accessed through the external debug interface:

Component	Offset
Debug	0xD2C

H9.2.25 EDECCR, External Debug Exception Catch Control Register

The EDECCR characteristics are:

Purpose

Controls Exception Catch debug events.

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	SLK	Default
Error	Error	Error	RO	RW

Configurations

External register EDECCR is architecturally mapped to AArch64 System register [OSECCR_EL1](#).

External register EDECCR is architecturally mapped to AArch32 System register [DBGOSECCR](#).

EDECCR is in the Core power domain. Some or all RW fields of this register have defined reset values. These apply only on a Cold reset. The register is not affected by a Warm reset and is not affected by an External debug reset.

Attributes

EDECCR is a 32-bit register.

Field descriptions

The EDECCR bit assignments are:

31	16 15	12 11	8 7	4 3	0
RES0		NSR<n>	SR<n>	NSE<n>	SE<n>

Bits [31:16]

Reserved, RES0.

NSR<n>, bits [15:12]

In ARMv8.2

Controls Non-secure exception catch on exception return to EL<n> in conjunction with NSE<n>. If EL3 and EL2 are not implemented and the PE behaves as if [SCR_EL3.NS](#) is set to 0, this field is reserved, RES0. Otherwise, possible values for this field are:

- 0 If the corresponding NSE<n> bit is 0, then Exception Catch debug events are disabled for Non-secure Exception level <n>.
 - If the corresponding NSE<n> bit is 1, then Exception Catch debug events are enabled for exception entry, reset entry and exception return to Non-secure Exception level <n>.
- 1 If the corresponding NSE<n> bit is 0, then Exception Catch debug events are enabled for exception returns to Non-secure Exception level <n>.
 - If the corresponding NSE<n> bit is 1, then Exception Catch debug events are enabled for exception entry and reset entry to Non-secure Exception level <n>.

Note

It is IMPLEMENTATION DEFINED whether a reset entry to an Exception level is permitted to generate an Exception Catch debug event.

NSR[3] is RES0.

If EL2 is not implemented, NSR[2] is RES0.

A value that enables an Exception Catch debug event for an Exception level that is not implemented is reserved. If this field is programmed with a reserved value then:

- The PE behaves as if it is programmed with a defined value, other than for a read of EDECCR.
- The value returned for NSR<n> by a read of EDECCR is UNKNOWN.

When this register has an architecturally-defined reset value, this field resets to 0.

In ARMv8.1 and ARMv8.0.

Reserved, RES0.

SR<n>, bits [11:8]

In ARMv8.2

Controls Secure exception catch on exception return to EL<n> in conjunction with SE<n>. If EL3 is not implemented and the PE behaves as if SCR_EL3.NS is set to 1, this field is reserved, RES0. Otherwise, possible values for this field are:

- 0
- If the corresponding SE<n> bit is 0, then Exception Catch debug events are disabled for Secure Exception level <n>.
- If the corresponding SE<n> bit is 1, then Exception Catch debug events are enabled for exception entry, reset entry and exception return to Secure Exception level <n>.
- 1
- If the corresponding SE<n> bit is 0, then Exception Catch debug events are enabled for exception returns to Secure Exception level <n>.
- If the corresponding SE<n> bit is 1, then Exception Catch debug events are enabled for exception entry and reset entry to Secure Exception level <n>.

Note

It is IMPLEMENTATION DEFINED whether a reset entry to an Exception level is permitted to generate an Exception Catch debug event.

SR[2] is RES0.

If EL3 is not implemented, SR[3] is RES0.

A value that enables an Exception Catch debug event for an Exception level that is not implemented is reserved. If this field is programmed with a reserved value then:

- The PE behaves as if it is programmed with a defined value, other than for a read of EDECCR.
- The value returned for SR<n> by a read of EDECCR is UNKNOWN.

If ExternalSecureInvasiveDebugEnabled() == FALSE, then this field is ignored.

When this register has an architecturally-defined reset value, this field resets to 0.

In ARMv8.1 and ARMv8.0.

Reserved, RES0.

NSE<n>, bits [7:4]

In ARMv8.2

Coarse-grained Non-secure exception catch for EL<n>. This controls whether Exception Catch debug events are enabled for Non-secure EL<n>. This also controls:

- The behavior of exception catch on exception entry to EL<n>.
- The behavior of exception catch on exception return to EL<n> in conjunction with NSR<n>.

If EL3 and EL2 are not implemented and the PE behaves as if SCR_EL3.NS is set to 0, this field is reserved, RES0. Otherwise, possible values for this field are:

- 0
- Exception Catch debug events are disabled for Non-secure Exception level <n>.

1 Exception Catch debug events are enabled for Non-secure Exception level <n>. NSE[3,0] are RES0.

A value that enables an Exception Catch debug event for an Exception level that is not implemented is reserved. If this field is programmed with a reserved value then:

- The PE behaves as if it is programmed with a defined value, other than for a read of EDECCR.
- The value returned for NSE<n> by a read of EDECCR is UNKNOWN.

When this register has an architecturally-defined reset value, this field resets to 0.

In ARMv8.1 and ARMv8.0.

Coarse-grained Non-secure exception catch. If EL3 and EL2 are not implemented and the PE behaves as if SCR_EL3.NS is set to 0, this field is reserved, RES0. Otherwise, possible values for this field are:

0000 Exception Catch debug event disabled for Non-secure Exception levels.
0010 Exception Catch debug event enabled for Non-secure EL1.
0100 Exception Catch debug event enabled for Non-secure EL2.
0110 Exception Catch debug event enabled for Non-secure EL1 and EL2.

All other values are reserved. A value that enables an Exception Catch debug event for an Exception level that is not implemented is reserved. If this field is programmed with a reserved value then:

- The PE behaves as if it is programmed with a defined value, other than for a read of EDECCR.
- The value returned for NSE by a read of EDECCR is UNKNOWN.

SE<n>, bits [3:0]

In ARMv8.2

Coarse-grained Secure exception catch for EL<n>. This field controls whether Exception Catch debug events are enabled for Secure EL<n>.

- The behavior of exception catch on exception entry to EL<n>.
- The behavior of exception catch on exception return to EL<n> in conjunction with SR<n>.

If EL3 is not implemented and the PE behaves as if SCR_EL3.NS is set to 1, this field is reserved, RES0. Otherwise, possible values for this field are:

0 Exception Catch debug events are disabled for Secure Exception level <n>.
1 Exception Catch debug events are enabled for Secure Exception level <n>.

SE[2,0] are RES0.

If EL3 is not implemented, SE[3] is RES0.

A value that enables an Exception Catch debug event for an Exception level that is not implemented is reserved. If this field is programmed with a reserved value then:

- The PE behaves as if it is programmed with a defined value, other than for a read of EDECCR.
- The value returned for SE<n> by a read of EDECCR is UNKNOWN.

If ExternalSecureInvasiveDebugEnabled() == FALSE, then this field is ignored.

When this register has an architecturally-defined reset value, this field resets to 0.

In ARMv8.1 and ARMv8.0.

Coarse-grained Secure exception catch. If EL3 is not implemented and the PE behaves as if SCR_EL3.NS is set to 1, this field is reserved, RES0. Otherwise, possible values for this field are:

0000 Exception Catch debug event disabled for Secure Exception levels.
0010 Exception Catch debug event enabled for Secure EL1.
1000 Exception Catch debug event enabled for Secure EL3.

1010 Exception Catch debug event enabled for Secure EL1 and EL3.

All other values are reserved. A value that enables an Exception Catch debug event for an Exception level that is not implemented is reserved. If this field is programmed with a reserved value then:

- The PE behaves as if it is programmed with a defined value, other than for a read of EDECCR.
- The value returned for SE by a read of EDECCR is UNKNOWN.

The NSR<n>, SR<n>, NSE<n>, and SE<n> fields combine to control Exception Catch as follows:

(N)SR<n>	(N)SE<n>	Behavior on exception return to ELn	Behavior on exception taken to ELn
0	0	No action	No action
0	1	Halt if allowed	Halt if allowed
1	0	Halt if allowed	No action
1	1	No action	Halt if allowed

Accessing the EDECCR:

EDECCR can be accessed through the external debug interface:

Component	Offset
Debug	0x098

H9.2.26 EDECR, External Debug Execution Control Register

The EDECR characteristics are:

Purpose

Controls Halting debug events.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RW

Configurations

EDECR is in the Debug power domain. Some or all RW fields of this register have defined reset values. These apply only on an External debug reset. The register is not affected by a Warm reset and is not affected by a Cold reset.

Attributes

EDECR is a 32-bit register.

Field descriptions

The EDECR bit assignments are:

Bits [31:3]

Reserved, RES0.

SS, bit [2]

Halting step enable. Possible values of this field are:

0 Halting step debug event disabled.

1 Halting step debug event enabled.

If the value of EDECR.SS is changed when the PE is in Non-debug state, behavior is CONSTRAINED UNPREDICTABLE as described in [Changing the value of EDECR.SS when not in Debug state on page H3-5483](#).

When this register has an architecturally-defined reset value, this field resets to 0.

RCE, bit [1]

Reset Catch enable. Possible values of this field are:

0 Reset Catch debug event disabled.

1 Reset Catch debug event enabled.

When this register has an architecturally-defined reset value, this field resets to 0.

OSUCE, bit [0]

OS Unlock Catch enabled. Possible values of this field are:

0 OS Unlock Catch debug event disabled.

1 OS Unlock Catch debug event enabled.

When this register has an architecturally-defined reset value, this field resets to 0.

Accessing the EDECR:

EDECR can be accessed through the external debug interface:

Component	Offset
Debug	0x024

H9.2.27 EDESR, External Debug Event Status Register

The EDESR characteristics are:

Purpose

Indicates the status of internally pending Halting debug events.

Usage constraints

This register is accessible as follows:

Off	DLK	SLK	Default
Error	Error	RO	RW

If a request to clear a pending Halting debug event is received at or about the time when halting becomes allowed, it is **CONSTRAINED UNPREDICTABLE** whether the event is taken.

If Core power is removed while a Halting debug event is pending, it is lost. However, it might become pending again when the Core is powered back on and Cold reset.

Configurations

EDESR is in the Core power domain. Some or all RW fields of this register have defined reset values. These apply on a Warm or Cold reset. The register is not affected by an External debug reset.

Attributes

EDESR is a 32-bit register.

Field descriptions

The EDESR bit assignments are:

Bits [31:3]

Reserved, RES0.

SS, bit [2]

Halting step debug event pending. Possible values of this field are:

- 0 Reading this means that a Halting step debug event is not pending. Writing this means no action.
- 1 Reading this means that a Halting step debug event is pending. Writing this clears the pending Halting step debug event.

When this register has an architecturally-defined reset value, this field resets to the value of [EDECR.SS](#).

RC, bit [1]

Reset Catch debug event pending. Possible values of this field are:

- 0 Reading this means that a Reset Catch debug event is not pending. Writing this means no action.

- 1 Reading this means that a Reset Catch debug event is pending. Writing this clears the pending Reset Catch debug event.

When this register has an architecturally-defined reset value, this field resets to the value of [EDEC.RCE](#).

OSUC, bit [0]

OS Unlock Catch debug event pending. Possible values of this field are:

- 0 Reading this means that an OS Unlock Catch debug event is not pending. Writing this means no action.
- 1 Reading this means that an OS Unlock Catch debug event is pending. Writing this clears the pending OS Unlock Catch debug event.

When this register has an architecturally-defined reset value, this field resets to 0.

Accessing the EDESR:

EDESR can be accessed through the external debug interface:

Component	Offset
Debug	0x020

H9.2.28 EDITCTRL, External Debug Integration mode Control register

The EDITCTRL characteristics are:

Purpose

Enables the external debug to switch from its default mode into integration mode, where test software can control directly the inputs and outputs of the PE, for integration testing or topology detection.

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	Default
IMP DEF	IMP DEF	IMP DEF	RW

Configurations

It is IMPLEMENTATION DEFINED whether EDITCTRL is implemented in the Core power domain or in the Debug power domain. Some or all RW fields of this register have defined reset values, and:

- The register is not affected by a Warm reset.
- If the register is implemented in the Core power domain the reset values apply on a Cold reset, and the register is not affected by an External debug reset.
- If the register is implemented in the Debug power domain the reset values apply on an External debug reset, and the register is not affected by a Cold reset.

Implementation of this register is OPTIONAL.

Attributes

EDITCTRL is a 32-bit register.

Field descriptions

The EDITCTRL bit assignments are:

Bits [31:1]

Reserved, RES0.

IME, bit [0]

Integration mode enable. When IME == 1, the device reverts to an integration mode to enable integration testing or topology detection. The integration mode behavior is IMPLEMENTATION DEFINED.

0 Normal operation.

1 Integration mode enabled.

When this register has an architecturally-defined reset value, this field resets to 0.

Accessing the EDITCTRL:

EDITCTRL can be accessed through the external debug interface:

Component	Offset
Debug	0xF00

H9.2.29 EDITR, External Debug Instruction Transfer Register

The EDITR characteristics are:

Purpose

Used in Debug state for passing instructions to the PE for execution.

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	SLK	Default
Error	Error	Error	WI	WO

If `EDSCR.ITE == 0` when the PE exits Debug state on receiving a Restart request trigger event, the behavior of any instruction issued through the ITR in Normal access mode that has not completed execution is **CONSTRAINED UNPREDICTABLE**, and must do one of the following:

- It must complete execution in Debug state before the PE executes the restart sequence.
- It must complete execution in Non-debug state before the PE executes the restart sequence.
- It must be abandoned. This means that the instruction does not execute. Any registers or memory accessed by the instruction are left in an UNKNOWN state.

EDITR ignores writes if the PE is in Non-debug state.

Configurations

EDITR is in the Core power domain.

Attributes

EDITR is a 32-bit register.

Field descriptions

The EDITR bit assignments are:

When in AArch32 state:

T32Second, bits [31:16]

Second halfword of the T32 instruction to be executed on the PE. When EDITR contains a 16-bit T32 instruction, this field is ignored. For more information see [Behavior in Debug state on page H2-5445](#)

T32First, bits [15:0]

First halfword of the T32 instruction to be executed on the PE.

When in AArch64 state:

Bits [31:0]

A64 instruction to be executed on the PE.

Accessing the EDITR:

EDITR can be accessed through the external debug interface:

Component	Offset
Debug	0x084

H9.2.30 EDLAR, External Debug Lock Access Register

The EDLAR characteristics are:

Purpose

Allows or disallows access to the external debug registers through a memory-mapped interface.

Usage constraints

This register is accessible as follows:

Default

WO

Configurations

EDLAR is in the Debug power domain.

If OPTIONAL memory-mapped access to the external debug interface is supported then an OPTIONAL Software Lock can be implemented as part of CoreSight compliance.

EDLAR ignores writes if the Software Lock is not implemented and ignores writes for other accesses to the external debug interface.

The Software Lock provides a lock to prevent memory-mapped writes to the debug registers. Use of this lock mechanism reduces the risk of accidental damage to the contents of the debug registers. It does not, and cannot, prevent all accidental or malicious damage.

Software uses EDLAR to set or clear the lock, and [EDLSR](#) to check the current status of the lock.

Attributes

EDLAR is a 32-bit register.

Field descriptions

The EDLAR bit assignments are:

KEY, bits [31:0]

Lock Access control. Writing the key value 0xC5ACCE55 to this field unlocks the lock, enabling write accesses to this component's registers through a memory-mapped interface.

Writing any other value to this register locks the lock, disabling write accesses to this component's registers through a memory mapped interface.

Accessing the EDLAR:

EDLAR can be accessed through a memory-mapped interface access to the external debug interface:

Component	Offset
Debug	0xFB0

H9.2.31 EDLSR, External Debug Lock Status Register

The EDLSR characteristics are:

Purpose

Indicates the current status of the software lock for external debug registers.

Usage constraints

This register is accessible as follows:

Default

RO

Configurations

EDLSR is in the Debug power domain. Some or all RW fields of this register have defined reset values. These apply only on an External debug reset. The register is not affected by a Warm reset and is not affected by a Cold reset.

If OPTIONAL memory-mapped access to the external debug interface is supported then an OPTIONAL Software Lock can be implemented as part of CoreSight compliance.

EDLSR is RAZ if the Software Lock is not implemented and is RAZ for other accesses to the external debug interface.

The Software Lock provides a lock to prevent memory-mapped writes to the debug registers. Use of this lock mechanism reduces the risk of accidental damage to the contents of the debug registers. It does not, and cannot, prevent all accidental or malicious damage.

Software uses [EDLAR](#) to set or clear the lock, and EDLSR to check the current status of the lock.

Attributes

EDLSR is a 32-bit register.

Field descriptions

The EDLSR bit assignments are:

Bits [31:3]

Reserved, RES0.

nTT, bit [2]

Not thirty-two bit access required. RAZ.

SLK, bit [1]

Software Lock status for this component. For an access to LSR that is not a memory-mapped access, or when the Software Lock is not implemented, this field is RES0.

For memory-mapped accesses when the Software Lock is implemented, possible values of this field are:

- 0 Lock clear. Writes are permitted to this component's registers.
- 1 Lock set. Writes to this component's registers are ignored, and reads have no side effects.

When this register has an architecturally-defined reset value, this field resets to 1.

SLI, bit [0]

Software Lock implemented. For an access to LSR that is not a memory-mapped access, this field is RAZ. For memory-mapped accesses, the value of this field is IMPLEMENTATION DEFINED.

Permitted values are:

- 0 Software Lock not implemented or not memory-mapped access.
- 1 Software Lock implemented and memory-mapped access.

Accessing the EDLSR:

EDLSR can be accessed through a memory-mapped interface access to the external debug interface:

Component	Offset
Debug	0xFB4

H9.2.32 EDPCSR, External Debug Program Counter Sample Register

The EDPCSR characteristics are:

Purpose

Holds a sampled instruction address value.

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	SLK	Default
Error	Error	Error	RO	RO

Configurations

EDPCSR is in the Core power domain.

Fields in this register reset to architecturally UNKNOWN values. These apply only on a Cold reset. The register is not affected by a Warm reset and is not affected by an External debug reset.

Implemented only if the OPTIONAL PC Sample-based Profiling Extension is implemented and [ARMv8.2-PCSample](#) is not implemented. If [ARMv8.2-PCSample](#) is implemented, this register is RES0 and the architecture defines the functionality in [PMPCSR](#).

Attributes

EDPCSR is a pair of 32-bit registers.

If [ARMv8.1-VHE](#) is implemented, the format of this register differs depending on the value of [EDSCR.SC2](#).

Field descriptions

The EDPCSR bit assignments are:

When ARMv8.1-VHE is not implemented:

Bits [63:32]

PC Sample high word, EDPCSRhi. If [EDVIDSR.HV](#) == 0 then this field is RAZ, otherwise bits [63:32] of the sampled instruction address value. The translation regime that EDPCSR samples can be determined from [EDVIDSR](#).{NS,E2,E3}.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

Bits [31:0]

PC Sample low word. EDPCSRlo, bits[31:0] of the sampled instruction address value. The translation regime that EDPCSR samples can be determined from [EDVIDSR](#).{NS,E2,E3}.

- For a read of EDPCSR[31:0] from the memory-mapped interface, if [EDLSR.SLK](#) == 1, meaning the OPTIONAL Software Lock is locked, then the access has no side-effects.
- In any other cases, a read of EDPCSR[31:0] has the side-effect of indirectly writing to EDPCSRhi, [EDCIDSR](#), and [EDVIDSR](#):
 - If the PE is in Debug state, or PC Sample-based profiling is prohibited, EDPCSRlo reads as 0xFFFFFFFF, and EDPCSRhi, [EDCIDSR](#), and [EDVIDSR](#) become UNKNOWN.

- If the PE is in Reset state, the sampled value is UNKNOWN and EDPCSRhi, EDCIDSR, and EDVIDSR become UNKNOWN.
- If no instruction has been retired since the PE left Reset state, Debug state, or a state where PC Sample-based Profiling is prohibited, the sampled value is UNKNOWN, and EDPCSRhi, EDCIDSR, and EDVIDSR become UNKNOWN.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

When ARMv8.1-VHE is implemented and EDSCR.SC2 == 0:

Bits [63:32]

PC Sample high word, EDPCSRhi. If EDVIDSR.HV == 0 then this field is RAZ, otherwise bits [63:32] of the sampled instruction address value. The translation regime that EDPCSR samples can be determined from EDVIDSR.{NS,E2,E3}.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

Bits [31:0]

PC Sample low word. EDPCSRlo, bits[31:0] of the sampled instruction address value. The translation regime that EDPCSR samples can be determined from EDVIDSR.{NS,E2,E3}.

- For a read of EDPCSR[31:0] from the memory-mapped interface, if EDLSR.SLK == 1, meaning the OPTIONAL Software Lock is locked, then the access has no side-effects.
- In any other cases, a read of EDPCSR[31:0] has the side-effect of indirectly writing to EDPCSRhi, EDCIDSR, and EDVIDSR:
 - If the PE is in Debug state, or PC Sample-based profiling is prohibited, EDPCSRlo reads as 0xFFFFFFFF, and EDPCSRhi, EDCIDSR, and EDVIDSR become UNKNOWN.
 - If the PE is in Reset state, the sampled value is UNKNOWN and EDPCSRhi, EDCIDSR, and EDVIDSR become UNKNOWN.
 - If no instruction has been retired since the PE left Reset state, Debug state, or a state where PC Sample-based Profiling is prohibited, the sampled value is UNKNOWN, and EDPCSRhi, EDCIDSR, and EDVIDSR become UNKNOWN.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

When ARMv8.1-VHE is implemented and EDSCR.SC2 == 1:

NS, bit [63]

Non-secure state sample. Indicates the Security state that is associated with the most recent EDPCSR sample.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

EL, bits [62:61]

Exception level status sample. Indicates the Exception level that is associated with the most recent EDPCSR sample.

- 00 Sample is from EL0.
- 01 Sample is from EL1.
- 10 Sample is from EL2.
- 11 Sample is from EL3.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

Bits [60:56]

Reserved, RES0.

Bits [55:32]

PC Sample high word, EDPCSRhi. Bits [55:32] of the sampled instruction address value. The translation regime that EDPCSR samples can be determined from EDPCSR.{NS,EL}.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

Bits [31:0]

PC Sample low word, EDPCSRlo. Bits[31:0] of the sampled instruction address value. The translation regime that EDPCSR samples can be determined from EDVIDSR.{NS,E2,E3}.

- For a read of EDPCSR[31:0] from the memory-mapped interface, if EDLSR.SLK == 1, meaning the OPTIONAL Software Lock is locked, then the access has no side-effects.
- In any other cases, a read of EDPCSR[31:0] has the side-effect of indirectly writing to EDPCSR[63:32], EDCIDSR, and EDVIDSR:
 - If the PE is in Debug state, or PC Sample-based profiling is prohibited, EDPCSR[31:0] reads as 0xFFFFFFFF, and EDPCSR[63:32], EDCIDSR, and EDVIDSR become UNKNOWN.
 - If the PE is in Reset state, the sampled value is UNKNOWN and EDPCSR[63:32], EDCIDSR, and EDVIDSR become UNKNOWN.
 - If no instruction has been retired since the PE left Reset state, Debug state, or a state where PC Sample-based Profiling is prohibited, the sampled value is UNKNOWN, and EDPCSR[63:32], EDCIDSR, and EDVIDSR become UNKNOWN.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

When ARMv8.2-PCSample is implemented:

Bits [63:0]

Reserved, RES0.

Accessing the EDPCSR:

EDPCSR[31:0] can be accessed through the external debug interface:

Component	Offset
Debug	0x0A0

EDPCSR[63:32] can be accessed through the external debug interface:

Component	Offset
Debug	0x0AC

H9.2.33 EDPFR, External Debug Processor Feature Register

The EDPFR characteristics are:

Purpose

Provides information about implemented PE features.

For general information about the interpretation of the ID registers see [Principles of the ID scheme for fields in ID registers on page D7-2195](#).

Usage constraints

This register is accessible as follows:

Off	DLK	Default
IMP DEF	IMP DEF	RO

Configurations

It is IMPLEMENTATION DEFINED whether EDPFR is implemented in the Core power domain or in the Debug power domain.

Attributes

EDPFR is a 64-bit register.

Field descriptions

The EDPFR bit assignments are:

Bits [63:36]

Reserved, RES0.

SVE, bits [35:32]

In ARMv8.2 and ARMv8.1

Present only if [SVE](#) is implemented.

Scalable Vector Extension. Defined values are:

0000 Scalable Vector Extension is not implemented.

0001 Scalable Vector Extension is implemented.

All other values are reserved.

If [SVE](#) is not implemented, this field is RES0.

In ARMv8.0.

Reserved, RES0.

UNK, bits [31:28]

This field is UNKNOWN.

GIC, bits [27:24]

System register GIC interface support. Defined values are:

0000 No System register interface to the GIC is supported.

0001 System register interface to versions 3.0 and 4.0 of the GIC CPU interface is supported.

All other values are reserved.

In an ARMv8-A implementation that supports AArch64 state in at least one Exception level, this field returns the value of [ID_AA64PFR0_EL1.GIC](#).

AdvSIMD, bits [23:20]

Advanced SIMD. Defined values are:

0000 Advanced SIMD is implemented, including support for the following SISO and SIMD operations:

- Integer byte, halfword, word and doubleword element operations.
- Single-precision and double-precision floating-point arithmetic.
- Conversions between single-precision and half-precision data types, and double-precision and half-precision data types.

0001 As for 0000, and also includes support for half-precision floating-point arithmetic.

1111 Advanced SIMD is not implemented.

All other values are reserved.

This field must have the same value as the FP field.

The permitted values are:

- 0000 in an implementation with Advanced SIMD support, that does not include the [ARMv8.2-FP16](#) extension.
- 0001 in an implementation with Advanced SIMD support, that includes the [ARMv8.2-FP16](#) extension.
- 1111 in an implementation without Advanced SIMD support.

In an ARMv8-A implementation that supports AArch64 state in at least one Exception level, this field returns the value of [ID_AA64PFR0_EL1.AdvSIMD](#).

FP, bits [19:16]

Floating-point. Defined values are:

0000 Floating-point is implemented, and includes support for:

- Single-precision and double-precision floating-point types.
- Conversions between single-precision and half-precision data types, and double-precision and half-precision data types.

0001 As for 0000, and also includes support for half-precision floating-point arithmetic.

1111 Floating-point is not implemented.

All other values are reserved.

This field must have the same value as the AdvSIMD field.

The permitted values are:

- 0000 in an implementation with floating-point support, that does not include the [ARMv8.2-FP16](#) extension.
- 0001 in an implementation with floating-point support, that includes the [ARMv8.2-FP16](#) extension.
- 1111 in an implementation without floating-point support.

In an ARMv8-A implementation that supports AArch64 state in at least one Exception level, this field returns the value of [ID_AA64PFR0_EL1.FP](#).

EL3, bits [15:12]

AArch64 EL3 Exception level handling. Defined values are:

0000 EL3 is not implemented or cannot be executed in AArch64 state.

0001 EL3 can be executed in AArch64 state only.

0010 EL3 can be executed in either AArch64 or AArch32 state.
When the value of `EDAA32PFR.EL3` is non-zero, this field must be 0000.
All other values are reserved.

In an ARMv8-A implementation that supports AArch64 state in at least one Exception level, this field returns the value of `ID_AA64PFR0_EL1.EL3`.

EL2, bits [11:8]

AArch64 EL2 Exception level handling. Defined values are:

0000 EL2 is not implemented or cannot be executed in AArch64 state.
0001 EL2 can be executed in AArch64 state only.
0010 EL2 can be executed in either AArch64 or AArch32 state.

When the value of `EDAA32PFR.EL2` is non-zero, this field must be 0000.
All other values are reserved.

In an ARMv8-A implementation that supports AArch64 state in at least one Exception level, this field returns the value of `ID_AA64PFR0_EL1.EL2`.

EL1, bits [7:4]

AArch64 EL1 Exception level handling. Defined values are:

0000 EL1 can be executed in AArch32 state only.
0001 EL1 can be executed in AArch64 state only.
0010 EL1 can be executed in either AArch64 or AArch32 state.

All other values are reserved.

In an ARMv8-A implementation that supports AArch64 state in at least one Exception level, this field returns the value of `ID_AA64PFR0_EL1.EL1`.

EL0, bits [3:0]

AArch64 EL0 Exception level handling. Defined values are:

0000 EL0 can be executed in AArch32 state only.
0001 EL0 can be executed in AArch64 state only.
0010 EL0 can be executed in either AArch64 or AArch32 state.

All other values are reserved.

In an ARMv8-A implementation that supports AArch64 state in at least one Exception level, this field returns the value of `ID_AA64PFR0_EL1.EL0`.

Accessing the EDPFR:

EDPFR[31:0] can be accessed through the external debug interface:

Component	Offset
Debug	0xD20

EDPFR[63:32] can be accessed through the external debug interface:

Component	Offset
Debug	0xD24

H9.2.34 EDPIDR0, External Debug Peripheral Identification Register 0

The EDPIDR0 characteristics are:

Purpose

Provides information to identify an external debug component.

For more information see [About the Peripheral identification scheme on page K2-6146](#).

Usage constraints

This register is accessible as follows:

Default

RO

Configurations

EDPIDR0 is in the Debug power domain.

Implementation of this register is OPTIONAL.

This register is required for CoreSight compliance.

Attributes

EDPIDR0 is a 32-bit register.

Field descriptions

The EDPIDR0 bit assignments are:

Bits [31:8]

Reserved, RES0.

PART_0, bits [7:0]

Part number, least significant byte.

Accessing the EDPIDR0:

EDPIDR0 can be accessed through the external debug interface:

Component	Offset
-----------	--------

Debug	0xFE0
-------	-------

H9.2.35 EDPIDR1, External Debug Peripheral Identification Register 1

The EDPIDR1 characteristics are:

Purpose

Provides information to identify an external debug component.

For more information see [About the Peripheral identification scheme on page K2-6146](#).

Usage constraints

This register is accessible as follows:

Default

RO

Configurations

EDPIDR1 is in the Debug power domain.

Implementation of this register is OPTIONAL.

This register is required for CoreSight compliance.

Attributes

EDPIDR1 is a 32-bit register.

Field descriptions

The EDPIDR1 bit assignments are:

Bits [31:8]

Reserved, RES0.

DES_0, bits [7:4]

Designer, least significant nibble of JEP106 ID code. For ARM Limited, this field is 0b1011.

PART_1, bits [3:0]

Part number, most significant nibble.

Accessing the EDPIDR1:

EDPIDR1 can be accessed through the external debug interface:

Component	Offset
-----------	--------

Debug	0xFE4
-------	-------

H9.2.36 EDPIDR2, External Debug Peripheral Identification Register 2

The EDPIDR2 characteristics are:

Purpose

Provides information to identify an external debug component.

For more information see [About the Peripheral identification scheme on page K2-6146](#).

Usage constraints

This register is accessible as follows:

Default
RO

Configurations

EDPIDR2 is in the Debug power domain.

Implementation of this register is OPTIONAL.

This register is required for CoreSight compliance.

Attributes

EDPIDR2 is a 32-bit register.

Field descriptions

The EDPIDR2 bit assignments are:

Bits [31:8]

Reserved, RES0.

REVISION, bits [7:4]

Part major revision. Parts can also use this field to extend Part number to 16-bits.

JEDEC, bit [3]

RAO. Indicates a JEP106 identity code is used.

DES_1, bits [2:0]

Designer, most significant bits of JEP106 ID code. For ARM Limited, this field is 0b011.

Accessing the EDPIDR2:

EDPIDR2 can be accessed through the external debug interface:

Component	Offset
Debug	0xFE8

H9.2.37 EDPIDR3, External Debug Peripheral Identification Register 3

The EDPIDR3 characteristics are:

Purpose

Provides information to identify an external debug component.

For more information see [About the Peripheral identification scheme on page K2-6146](#).

Usage constraints

This register is accessible as follows:

Default

RO

Configurations

EDPIDR3 is in the Debug power domain.

Implementation of this register is OPTIONAL.

This register is required for CoreSight compliance.

Attributes

EDPIDR3 is a 32-bit register.

Field descriptions

The EDPIDR3 bit assignments are:

Bits [31:8]

Reserved, RES0.

REVAND, bits [7:4]

Part minor revision. Parts using [EDPIDR2.REVISION](#) as an extension to the Part number must use this field as a major revision number.

CMOD, bits [3:0]

Customer modified. Indicates someone other than the Designer has modified the component.

Accessing the EDPIDR3:

EDPIDR3 can be accessed through the external debug interface:

Component	Offset
-----------	--------

Debug	0xFEC
-------	-------

H9.2.38 EDPIDR4, External Debug Peripheral Identification Register 4

The EDPIDR4 characteristics are:

Purpose

Provides information to identify an external debug component.

For more information see [About the Peripheral identification scheme on page K2-6146](#).

Usage constraints

This register is accessible as follows:

Default

RO

Configurations

EDPIDR4 is in the Debug power domain.

Implementation of this register is OPTIONAL.

This register is required for CoreSight compliance.

Attributes

EDPIDR4 is a 32-bit register.

Field descriptions

The EDPIDR4 bit assignments are:

Bits [31:8]

Reserved, RES0.

SIZE, bits [7:4]

Size of the component. RAZ. \log_2 of the number of 4KB pages from the start of the component to the end of the component ID registers.

DES_2, bits [3:0]

Designer, JEP106 continuation code, least significant nibble. For ARM Limited, this field is 0b0100.

Accessing the EDPIDR4:

EDPIDR4 can be accessed through the external debug interface:

Component **Offset**

Debug 0xFD0

H9.2.39 EDPRCR, External Debug Power/Reset Control Register

The EDPRCR characteristics are:

Purpose

Controls the PE functionality related to powerup, reset, and powerdown.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RW

On permitted accesses to the register, other access controls affect the behavior of some fields. See the field descriptions for more information.

Configurations

EDPRCR contains fields that are in the Core power domain and fields that are in the Debug power domain.

For RW fields see the field description for a description of the behavior of the field on a reset that applies to its power domain. However:

- Fields that are in the Core power domain are not affected by a warm reset and are not affected by an External debug reset.
- Fields that are in the Debug power domain reset to their defined reset values on an External debug reset, and are not affected by a Warm reset and are not affected by a Cold reset.

CORENPDRQ is the only field that is mapped between the EDPRCR and DBGPRCR and DBGPRCR_EL1.

Attributes

EDPRCR is a 32-bit register.

Field descriptions

The EDPRCR bit assignments are:

Bits [31:4]

Reserved, RES0.

COREPURQ, bit [3]

Core powerup request. Allows a debugger to request that the power controller power up the core, enabling access to the debug register in the Core power domain. The actions on writing to this bit are:

- 0 Do not request power up of the Core power domain.

1 Request power up of the Core power domain, and emulation of powerdown.

In an implementation that includes the recommended external debug interface, this bit drives the DBGPWRUPREQ signal.

Typically, this request is passed to an external power controller. This means that whether a request causes power up is dependent on the IMPLEMENTATION DEFINED nature of the system.

This field is in the Debug power domain and can be read and written when the Core power domain is powered off. On an External debug reset this field resets to 0.

The power controller must not allow the Core power domain to switch off while this bit is 1.

When this register has an architecturally-defined reset value, this field resets to 0.

This field is accessible as shown below:

SLK	Default
RO	RW

[Access permissions for the External debug interface registers on page H8-5567](#) describes the conditions shown in this table. These conditions are prioritized, with the leftmost condition having the highest priority and priority decreasing from left to right.

Bit [2]

Reserved, RES0.

CWRR, bit [1]

Warm reset request. Write only bit that reads as zero. The actions on writing to this bit are:

- 0 No action.
- 1 Request Warm reset.

The PE ignores writes to this bit if any of the following are true:

- ExternalInvasiveDebugEnabled() == FALSE, EL3 is not implemented, and the implemented Security state is Non-Secure state.
- ExternalSecureInvasiveDebugEnabled() == FALSE and one of the following is true:
 - EL3 is implemented.
 - The implemented Security state is Secure state.
- The Core power domain is either off or in a low-power state where the Core power domain registers cannot be accessed.
- DoubleLockStatus() == TRUE (OS Double Lock is set).
- OSLSR.OSLK == 1 (OS lock is locked).

In an implementation that includes the recommended external debug interface, this bit drives the DBGRSTREQ signal.

The extent of the reset is IMPLEMENTATION DEFINED, but must be one of:

- The request is ignored.
- Only this PE is Warm reset.
- This PE and other components of the system, possibly including other PEs, are Warm reset.

———— Note —————

Although the ARM architecture permits the first option from the above list, ARM recommends that either of the other options is implemented.

When this register has an architecturally-defined reset value, this field resets to 0.

This field is accessible as shown below:

Off	DLK	OSLK	SLK	Default
WI	WI	WI	WI	WO

Access permissions for the External debug interface registers on page H8-5567 describes the conditions shown in this table. These conditions are prioritized, with the leftmost condition having the highest priority and priority decreasing from left to right.

CORENPDRQ, bit [0]

Core no powerdown request. Requests emulation of powerdown. Possible values of this bit are:

- 0 If the system responds to a powerdown request, it powers down Core power domain.
- 1 If the system responds to a powerdown request, it does not powerdown the Core power domain, but instead emulates a powerdown of that domain.

This bit is UNKNOWN, and the PE ignores writes to this bit if any of the following are true:

- The Core power domain is either off or in a low-power state where the Core power domain registers cannot be accessed.
- DoubleLockStatus() == TRUE (OS Double Lock is set).
- OSLSR.OSLK == 1 (OS lock is locked).

Permitted accesses to this field map to the [DBGPRCR.CORENPDRQ](#) and [DBGPRCR_EL1.CORENPDRQ](#) fields.

This field is in the Core reset domain. See the descriptions of the [DBGPRCR.CORENPDRQ](#) and [DBGPRCR_EL1.CORENPDRQ](#) fields for information about the effect of a Cold reset on the value returned by a permitted read of this field.

This field is accessible as shown below:

Off	DLK	OSLK	SLK	Default
WI	WI	WI	RO	RW

Access permissions for the External debug interface registers on page H8-5567 describes the conditions shown in this table. These conditions are prioritized, with the leftmost condition having the highest priority and priority decreasing from left to right.

Accessing the EDPRCR:

EDPRCR can be accessed through the external debug interface:

Component	Offset
Debug	0x310

H9.2.40 EDPRSR, External Debug Processor Status Register

The EDPRSR characteristics are:

Purpose

Holds information about the reset and powerdown state of the PE.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

On permitted accesses to the register, other access controls affect the behavior of some fields. See the field descriptions for more information.

If the Core power domain is powered up ($\text{EDPRSR.PU} == 1$), then following a read of EDPRSR:

- If $\text{DoubleLockStatus()} == \text{FALSE}$, then:
 - $\text{EDPRSR}\{ \text{SDR}, \text{SPMAD}, \text{SDAD}, \text{SPD} \}$ are cleared to 0.
 - EDPRSR.SR is cleared to 0 if the non-debug logic of the PE is not in reset state ($\text{EDPRSR.R} == 0$).
- Otherwise it is **CONSTRAINED UNPREDICTABLE** whether or not this clearing occurs.

If the Core power domain is powered down ($\text{EDPRSR.PU} == 0$), then:

- $\text{EDPRSR}\{ \text{SDR}, \text{SPMAD}, \text{SDAD}, \text{SR} \}$ are all **UNKNOWN**, and are either reset or restored on being powered up.
- EDPRSR.SPD is not cleared following a read of EDPRSR. See the SPD bit description for more information.

The clearing of bits is an indirect write to EDPRSR.

Configurations

EDPRSR contains fields that are in the Core power domain and fields that are in the Debug power domain.

Some of the fields in the Core power domain are in the Cold reset domain and others are in the Warm reset domain. See the field descriptions for more information. However:

- Fields that are in the Cold reset domain are not affected by a warm reset and are not affected by an External debug reset.
- Fields in the Warm reset domain are also reset by a Cold reset but are not affected by an External debug reset.
- Fields in the Debug power domain are not affected by a Warm reset and are not affected by a Cold reset.

Attributes

EDPRSR is a 32-bit register.

Field descriptions

The EDPRSR bit assignments are:

Bits [31:12]

Reserved, RES0.

SDR, bit [11]

Sticky debug restart. Set to 1 when the PE exits Debug state.

This bit is UNKNOWN on reads if any of the following are true:

- DoubleLockStatus() == TRUE. The OS double-lock is locked.
- EDPRSR.R == 1. The PE is in Reset state.
- EDPRSR.PU == 0. The Core power domain is powered down.

Otherwise permitted values are:

- 0 The PE has not restarted since EDPRSR was last read.
- 1 The PE has restarted since EDPRSR was last read.

Note

If a reset occurs when the PE is in Debug state, the PE exits Debug state. SDR is UNKNOWN on Warm reset, meaning a debugger must also use the SR bit to determine whether the PE has left Debug state.

If EDPRSR.PU reads as 1, which means that the Core power domain is in a powerup state, then following a read of EDPRSR:

- If DoubleLockStatus() == FALSE this bit clears to 0.
- If DoubleLockStatus() == TRUE, it is CONSTRAINED UNPREDICTABLE whether this bit clears to 0 or is unchanged.

This field is in the Core power domain and the Warm reset domain. On a Warm or Cold reset it resets to an UNKNOWN value.

This field resets to a value that is architecturally UNKNOWN.

This field is accessible as shown below:

Off	DLK	SLK	Default
UNK	UNK	RO	RC

Access permissions for the External debug interface registers on page H8-5567 describes the conditions shown in this table. These conditions are prioritized, with the leftmost condition having the highest priority and priority decreasing from left to right.

SPMAD, bit [10]

Sticky EPMAD error. Set to 1 if an external debug interface access to a Performance Monitors register returns an error because AllowExternalPMUAccess() == FALSE.

This bit is UNKNOWN on reads if any of the following are true:

- DoubleLockStatus() == TRUE
- EDPRSR.{OSLK, R} is 1.
- EDPRSR.PU is 0.

Otherwise permitted values are:

- | | |
|---|---|
| 0 | No accesses to the external Performance Monitors registers have failed since EDPRSR was last read. |
| 1 | At least one access to the external Performance Monitors registers has failed since EDPRSR was last read. |

If the Core power domain is powered up, then, following a read of EDPRSR:

- If DoubleLockStatus() == FALSE this bit clears to 0.
- If DoubleLockStatus() == TRUE, it is CONSTRAINED UNPREDICTABLE whether this bit clears to 0 or is unchanged.

The write to SPMAD is an indirect write to EDPRSR that is a side effect of the access. The indirect write might not occur for a memory-mapped access to the external debug interface.

This field is in the Core power domain and the Cold reset domain. On a Cold reset it resets to 0.

When this register has an architecturally-defined reset value, this field resets to 0.

This field is accessible as shown below:

Off	DLK	OSLK	SLK	Default
UNK	UNK	UNK	RO	RC

[Access permissions for the External debug interface registers on page H8-5567](#) describes the conditions shown in this table. These conditions are prioritized, with the leftmost condition having the highest priority and priority decreasing from left to right.

EPMAD, bit [9]

External Performance Monitors access disable status.

This bit is UNKNOWN on reads if any of the following is true:

- DoubleLockStatus() == TRUE
- EDPRSR.{OSLK, R} is 1.
- EDPRSR.PU is 0.

Otherwise permitted values are:

- | | |
|---|---|
| 0 | External Performance Monitors access enabled. AllowExternalPMUAccess() == TRUE. |
| 1 | External Performance Monitors access disabled. AllowExternalPMUAccess() == FALSE. |

If external performance monitors access is not implemented, EPMAD is RAO.

This field is in the Core power domain.

This field is accessible as shown below:

Off	DLK	OSLK	EPMAD	Default
UNK	UNK	UNK	RAO	RO

[Access permissions for the External debug interface registers on page H8-5567](#) describes the conditions shown in this table. These conditions are prioritized, with the leftmost condition having the highest priority and priority decreasing from left to right.

SDAD, bit [8]

Sticky EDAD error. Set to 1 if an external debug interface access to a debug register returns an error because `AllowExternalDebugAccess() == FALSE`.

This bit is UNKNOWN on reads if any of the following are true:

- `DoubleLockStatus() == TRUE`
- `EDPRSR.R` is 1.
- `EDPRSR.PU` is 0.
- `EDPRSR.OSLK` is 1 and external debug writes to [OSLAR_EL1](#) do not return an error when `AllowExternalDebugAccess() == FALSE`.

Otherwise permitted values are:

- | | |
|---|---|
| 0 | No accesses to the external debug registers have failed since <code>EDPRSR</code> was last read. |
| 1 | At least one access to the external debug registers has failed since <code>EDPRSR</code> was last read. |

If the Core power domain is powered up, then, following a read of `EDPRSR`:

- If `DoubleLockStatus() == FALSE` this bit clears to 0.
- If `DoubleLockStatus() == TRUE`, it is CONSTRAINED UNPREDICTABLE whether this bit clears to 0 or is unchanged.

The write to `SDAD` is an indirect write to `EDPRSR` that is a side effect of the access. The indirect write might not occur for a memory-mapped access to the external debug interface.

This field is in the Core power domain and the Cold reset domain. On a Cold reset it resets to 0.

When this register has an architecturally-defined reset value, this field resets to 0.

This field is accessible as shown below:

Off	DLK	OSLK	SLK	Default
UNK	UNK	See text	RO	RC

[Access permissions for the External debug interface registers on page H8-5567](#) describes the conditions shown in this table. These conditions are prioritized, with the leftmost condition having the highest priority and priority decreasing from left to right.

EDAD, bit [7]

External debug access disable status.

This bit is UNKNOWN on reads if any of the following are true:

- `DoubleLockStatus() == TRUE`
- `EDPRSR.R` is 1.
- `EDPRSR.PU` is 0.
- `EDPRSR.OSLK` is 1 and external debug writes to [OSLAR_EL1](#) do not return an error when `AllowExternalDebugAccess() == FALSE`.

Otherwise permitted values are:

- | | |
|---|--|
| 0 | External debug access enabled. <code>AllowExternalDebugAccess() == TRUE</code> . |
| 1 | External debug access disabled. <code>AllowExternalDebugAccess() == FALSE</code> . |

This field is in the Core power domain.

This field is accessible as shown below:

Off	DLK	OSLK	EDAD	Default
UNK	UNK	See text	RAO	RAZ

[Access permissions for the External debug interface registers on page H8-5567](#) describes the conditions shown in this table. These conditions are prioritized, with the leftmost condition having the highest priority and priority decreasing from left to right.

DLK, bit [6]

OS Double Lock status bit. Returns the result of the pseudocode function DoubleLockStatus().

This bit is UNKNOWN on reads if EDPRSR.PU is 0.

Otherwise reads as zero if any of the following are true, that is when DoubleLockStatus() == FALSE:

- [OSDLR_EL1](#).DLK == 0.
- [DBGPRCR_EL1](#).CORENPDRQ == 1.
- The PE is in Debug state.

In ARMv8.0 and ARMv8.1, if the Core power domain is powered up and DoubleLockStatus() == TRUE, it is IMPLEMENTATION DEFINED whether:

- EDPRSR.PU reads as 1, EDPRSR.DLK reads as 1, and EDPRSR.SPD is UNKNOWN.
- EDPRSR.PU reads as 0, EDPRSR.DLK is UNKNOWN, and EDPRSR.SPD reads as 0.

From ARMv8.2, if the Core power domain is powered up and DoubleLockStatus() == TRUE, then EDPRSR.PU reads as 0, EDPRSR.DLK is UNKNOWN, and EDPRSR.SPD reads as 0.

If the Core power domain is powered up and entered reset state with the OS double-lock locked this bit has a CONSTRAINED UNPREDICTABLE value, for more information see [EDPRSR.{DLK, R} and reset state on page H6-5538](#)

EDPRSR.{DLK, SPD, PU} describe whether registers in the Core power domain can be accessed, and whether their state has been lost since the last time the register was read. For more information, see [EDPRSR.{DLK, SPD, PU} and the Core power domain on page H6-5537](#)

———— Note —————

Use of this bit by debuggers is deprecated from ARMv8.2.

This field is in the Core power domain.

This field is accessible as shown below:

Off	DLK	Default
UNK	See text	RAZ

[Access permissions for the External debug interface registers on page H8-5567](#) describes the conditions shown in this table. These conditions are prioritized, with the leftmost condition having the highest priority and priority decreasing from left to right.

OSLK, bit [5]

OS lock status bit.

This bit is UNKNOWN on reads if either:

- DoubleLockStatus() == TRUE
- EDPRSR.R is 1.
- EDPRSR.PU is 0.

A read of this bit returns the value of `OSLSR_EL1.OSLK`.

This field is in the Core power domain.

This field is accessible as shown below:

Off	DLK	OSLK	Default
UNK	UNK	RAO	RAZ

[Access permissions for the External debug interface registers on page H8-5567](#) describes the conditions shown in this table. These conditions are prioritized, with the leftmost condition having the highest priority and priority decreasing from left to right.

HALTED, bit [4]

Halted status bit.

This bit is UNKNOWN on reads if `EDPRSR.PU` is 0.

Otherwise permitted values are:

0 PE is in Non-debug state.

1 PE is in Debug state.

Because the OS Double Lock is never set when the PE is in Debug state, this bit is always RAZ when `DoubleLockStatus() == TRUE`.

This field is in the Core power domain.

This field is accessible as shown below:

Off	DLK	Default
UNK	See text	RO

[Access permissions for the External debug interface registers on page H8-5567](#) describes the conditions shown in this table. These conditions are prioritized, with the leftmost condition having the highest priority and priority decreasing from left to right.

SR, bit [3]

Sticky core reset status bit.

This bit is UNKNOWN on reads if either:

- `DoubleLockStatus() == TRUE`
- `EDPRSR.PU` is 0.

Otherwise permitted values are:

0 The non-debug logic of the PE is not in reset state and has not been reset since the last time `EDPRSR` was read.

1 The non-debug logic of the PE is in reset state or has been reset since the last time `EDPRSR` was read.

If `EDPRSR.PU` reads as 1 and `EDPRSR.R` reads as 0, which means that the Core power domain is in a powerup state and that the non-debug logic of the PE is not in reset state, then following a read of `EDPRSR`:

- If `DoubleLockStatus() == FALSE` this bit clears to 0.
- If `DoubleLockStatus() == TRUE`, it is UNPREDICTABLE whether this bit clears to 0 or is unchanged.

This field is in the Core power domain and the Warm reset domain. On a Warm or Cold reset it resets to 1.

When this register has an architecturally-defined reset value, this field resets to 1.

This field is accessible as shown below:

Off	DLK	SLK	Default
UNK	UNK	RO	RC

[Access permissions for the External debug interface registers on page H8-5567](#) describes the conditions shown in this table. These conditions are prioritized, with the leftmost condition having the highest priority and priority decreasing from left to right.

R, bit [2]

PE reset status bit.

This bit is UNKNOWN on reads if either:

- DoubleLockStatus() == TRUE
- EDPRSR.PU is 0.

Otherwise permitted values are:

- 0 The non-debug logic of the PE is not in reset state.
- 1 The non-debug logic of the PE is in reset state.

If the Core power domain is powered up and entered reset state with the OS double-lock locked this bit has a CONSTRAINED UNPREDICTABLE value, for more information see [EDPRSR.{DLK, R} and reset state on page H6-5538](#)

This field is in the Core power domain.

This field is accessible as shown below:

Off	DLK	Default
UNK	UNK	RO

[Access permissions for the External debug interface registers on page H8-5567](#) describes the conditions shown in this table. These conditions are prioritized, with the leftmost condition having the highest priority and priority decreasing from left to right.

SPD, bit [1]

Sticky core powerdown status bit.

This bit is UNKNOWN on reads if EDPRSR.PU is 1 and DoubleLockStatus() == TRUE .

Otherwise, permitted values are:

- 0 If EDPRSR.PU is 0, it is not known whether the state of the debug registers in the Core power domain is lost.
If EDPRSR.PU is 1, the state of the debug registers in the Core power domain has not been lost.
- 1 The state of the debug registers in the Core power domain has been lost.

If the Core power domain is powered up, then, following a read of EDPRSR:

- If DoubleLockStatus() == FALSE this bit clears to 0.
- If DoubleLockStatus() == TRUE, it is CONSTRAINED UNPREDICTABLE whether this bit clears to 0 or is unchanged.

When the value of EDPRSR.PU is 0 indicating that the Core power domain is in either retention or powerdown state, EDPRSR.SPD reads as 0. For more information, see [EDPRSR.SPD when the Core domain is in either retention or powerdown state on page H6-5537](#).

EDPRSR.{DLK, SPD, PU} describe whether registers in the Core power domain can be accessed, and whether their state has been lost since the last time the register was read. For more information, see [EDPRSR.{DLK, SPD, PU} and the Core power domain on page H6-5537](#).

This field is in the Core power domain and the Cold reset domain. On a Cold reset it resets to 1.
When this register has an architecturally-defined reset value, this field resets to 1.
This field is accessible as shown below:

Off	DLK	SLK	Default
RO	UNK	RO	RC

[Access permissions for the External debug interface registers on page H8-5567](#) describes the conditions shown in this table. These conditions are prioritized, with the leftmost condition having the highest priority and priority decreasing from left to right.

PU, bit [0]

Core powerup status bit. Indicates whether the Core power domain debug registers can be accessed.
When the Core power domain is powered-up and OS double-lock is locked, then:

- When [ARMv8.2-Debug](#) is implemented, the value of EDPRSR.PU reads as 0.
- When [ARMv8.2-Debug](#) is not implemented, the value of EDPRSR.PU is IMPLEMENTATION DEFINED.

See the description of DLK for more information.

Otherwise, permitted values are:

- 0 Core is in a low-power or powerdown state where the debug registers cannot be accessed.
- 1 Core is in a powerup state where the debug registers can be accessed.

If the Core power domain is powered up and entered reset state with the OS double-lock locked this bit has a CONSTRAINED UNPREDICTABLE value, for more information see [EDPRSR.{DLK, R} and reset state on page H6-5538](#)

EDPRSR.{DLK, SPD, PU} describe whether registers in the Core power domain can be accessed, and whether their state has been lost since the last time the register was read. For more information, see [EDPRSR.{DLK, SPD, PU} and the Core power domain on page H6-5537](#)

This field is accessible as shown below:

Off	DLK	Default
RAZ	See text	RAO

[Access permissions for the External debug interface registers on page H8-5567](#) describes the conditions shown in this table. These conditions are prioritized, with the leftmost condition having the highest priority and priority decreasing from left to right.

Accessing the EDPRSR:

EDPRSR can be accessed through the external debug interface:

Component	Offset
Debug	0x314

H9.2.41 EDRCR, External Debug Reserve Control Register

The EDRCR characteristics are:

Purpose

This register is used to allow imprecise entry to Debug state and clear sticky bits in [EDSCR](#).

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	SLK	Default
Error	Error	Error	WI	WO

Configurations

EDRCR is in the Core power domain.

Attributes

EDRCR is a 32-bit register.

Field descriptions

The EDRCR bit assignments are:

Bits [31:5]

Reserved, RES0.

CBRRQ, bit [4]

Allow imprecise entry to Debug state. The actions on writing to this bit are:

0 No action.

1 Allow imprecise entry to Debug state, for example by canceling pending bus accesses.

Setting this bit to 1 allows a debugger to request imprecise entry to Debug state. An External Debug Request debug event must be pending before the debugger sets this bit to 1.

This feature is optional. If this feature is not implemented, writes to this bit are ignored.

CSPA, bit [3]

Clear Sticky Pipeline Advance. This bit is used to clear the [EDSCR](#).PipeAdv bit to 0. The actions on writing to this bit are:

0 No action.

1 Clear the [EDSCR](#).PipeAdv bit to 0.

CSE, bit [2]

Clear Sticky Error. Used to clear the **EDSCR** cumulative error bits to 0. The actions on writing to this bit are:

- 0 No action.
- 1 Clear the **EDSCR**.{TXU, RXO, ERR} bits, and, if the PE is in Debug state, the **EDSCR.ITO** bit, to 0.

Bits [1:0]

Reserved, RES0.

Accessing the EDRCR:

EDRCR can be accessed through the external debug interface:

Component	Offset
Debug	0x090

H9.2.42 EDSCR, External Debug Status and Control Register

The EDSCR characteristics are:

Purpose

Main control register for the debug implementation.

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	SLK	Default
Error	Error	Error	RO	RW

Configurations

EDSCR is in the Core power domain. Some or all RW fields of this register have defined reset values. These apply only on a Cold reset. The register is not affected by a Warm reset and is not affected by an External debug reset.

Attributes

EDSCR is a 32-bit register.

Field descriptions

The EDSCR bit assignments are:

Bit [31]

Reserved, RES0.

RXfull, bit [30]

DTRRX full. This bit is RO.

When this register has an architecturally-defined reset value, this field resets to 0.

TXfull, bit [29]

DTRTX full. This bit is RO.

When this register has an architecturally-defined reset value, this field resets to 0.

ITO, bit [28]

ITR overrun. This bit is RO.

If the PE is in Non-debug state, this bit is UNKNOWN. ITO is set to 0 on entry to Debug state.

RXO, bit [27]

DTRRX overrun. This bit is RO.

When this register has an architecturally-defined reset value, this field resets to 0.

TXU, bit [26]

DTRTX underrun. This bit is RO.

When this register has an architecturally-defined reset value, this field resets to 0.

PipeAdv, bit [25]

Pipeline advance. This bit is RO. Set to 1 every time the PE pipeline retires one or more instructions. Cleared to 0 by a write to [EDRCR.CSPA](#).

The architecture does not define precisely when this bit is set to 1. It requires only that this happen periodically in Non-debug state to indicate that software execution is progressing.

ITE, bit [24]

ITR empty. This bit is RO.

If the PE is in Non-debug state, this bit is UNKNOWN. It is always valid in Debug state.

INTdis, bits [23:22]

Interrupt disable. Disables taking interrupts (including virtual interrupts and System Error interrupts) in Non-Debug state.

If `ExternalInvasiveDebugEnabled() = FALSE`, the value of this field is ignored.

If `ExternalInvasiveDebugEnabled() = TRUE`, the possible values of this field are:

- | | |
|----|--|
| 00 | Do not disable interrupts. |
| 01 | Disable interrupts taken to Non-secure EL1. |
| 10 | Disable interrupts taken only to Non-secure EL1 and Non-secure EL2. If external secure invasive debug is enabled, also disable interrupts taken to Secure EL1. |
| 11 | Disable interrupts taken only to Non-secure EL1 and Non-secure EL2. If external secure invasive debug is enabled, also disable all other interrupts. |

The value of INTdis does not affect whether an interrupt is a WFI wake-up event, but can mask an interrupt as a WFE wake-up event.

If EL3 and EL2 are not implemented, the values 0b01 and 0b10 are reserved. If programmed with a reserved value the PE behaves as if INTdis has been programmed with a defined value, other than for a direct read of EDSCR, and the value returned by a read of EDSCR.INTdis is UNKNOWN.

When this register has an architecturally-defined reset value, this field resets to 0.

TDA, bit [21]

Traps accesses to the following Debug System registers:

- AArch64: [DBGBCR<n>_EL1](#), [DBGBVR<n>_EL1](#), [DBGWCR<n>_EL1](#), [DBGWVR<n>_EL1](#).
- AArch32: [DBGBCR<n>](#), [DBGBVR<n>](#), [DBGXVR<n>](#), [DBGWCR<n>](#), [DBGWVR<n>](#).

The possible values of this field are:

- | | |
|---|--|
| 0 | Accesses to Debug System registers do not generate a Software Access debug event. |
| 1 | Accesses to Debug System registers generate a Software Access debug event, if OSLSR.OSLK is 0 and if halting is allowed. |

When this register has an architecturally-defined reset value, this field resets to 0.

MA, bit [20]

Memory access mode. Controls use of memory-access mode for accessing ITR and the DCC. This bit is ignored if in Non-debug state and set to zero on entry to Debug state.

Possible values of this field are:

- 0 Normal access mode.
- 1 Memory access mode.

SC2, bit [19]

In ARMv8.1

Sample CONTEXTIDR_EL2. Controls whether the Sample-based Profiling Extension samples CONTEXTIDR_EL2 or VTTBR_EL2.VMID.

- 0 Sample VTTBR_EL2.VMID.
- 1 Sample CONTEXTIDR_EL2.

If the PC Sample-based Profiling Extension is not implemented, then this field is RES0.

In ARMv8.2 and ARMv8.0.

Reserved, RES0.

NS, bit [18]

Non-secure status. Read-only. When in Debug state, gives the current Security state:

- 0 Secure state, IsSecure() == TRUE.
- 1 Non-secure state, IsSecure() == FALSE.

In Non-debug state, this bit is UNKNOWN.

Bit [17]

Reserved, RES0.

SDD, bit [16]

Secure debug disabled. This bit is RO.

On entry to Debug state:

- If entering in Secure state, SDD is set to 0.
- If entering in Non-secure state, SDD is set to the inverse of ExternalSecureInvasiveDebugEnabled().

In Debug state, the value of the SDD bit does not change, even if ExternalSecureInvasiveDebugEnabled() changes.

In Non-debug state:

- SDD returns the inverse of ExternalSecureInvasiveDebugEnabled(). If the authentication signals that control ExternalSecureInvasiveDebugEnabled() change, a context synchronization event is required to guarantee their effect.
- This bit is unaffected by the Security state of the PE.

If EL3 is not implemented and the implementation is Non-secure, this bit is RES1.

Bit [15]

Reserved, RES0.

HDE, bit [14]

Halting debug enable. The possible values of this field are:

- 0 Halting disabled for Breakpoint, Watchpoint and Halt Instruction debug events.
- 1 Halting enabled for Breakpoint, Watchpoint and Halt Instruction debug events.

When this register has an architecturally-defined reset value, this field resets to 0.

RW, bits [13:10]

Exception level Execution state status. Read-only. In Debug state, each bit gives the current Execution state of each EL:

RW	Meaning
1111	All Exception levels are using AArch64.
1110	EL0 is using AArch32. All other Exception levels are using AArch64.
110x	EL0 and EL1 are using AArch32. All other Exception levels are using AArch64. Never seen if EL2 is not implemented in the current Security state.
10xx	EL0, EL1, and, if implemented in the current Security state, EL2 are using AArch32. All other Exception levels are using AArch64.
0xxx	All Exception levels are using AArch32.

However:

- The value of 1110 is only permitted at EL0.
- The values 110x are not permitted if either:
 - EL2 is not implemented.
 - EL3 is implemented and SCR_EL3.NS/SCR.NS == 0.
- The values 10xx are not permitted if EL3 is not implemented.

In Non-debug state, this field is RAO.

EL, bits [9:8]

Exception level. Read-only. In Debug state, this gives the current EL of the PE.

In Non-debug state, this field is RAZ.

A, bit [7]

System Error interrupt pending. Read-only. In Debug state, indicates whether a SError interrupt is pending:

- If [HCR_EL2](#).{AMO, TGE} = {1, 0} and in Non-secure EL0 or EL1, a virtual SError interrupt.
 - Otherwise, a physical SError interrupt.
- 0 No SError interrupt pending.
1 SError interrupt pending.

A debugger can read EDSCR to check whether an SError interrupt is pending without having to execute further instructions. A pending SError might indicate data from target memory is corrupted. UNKNOWN in Non-debug state.

ERR, bit [6]

Cumulative error flag. This field is RO. It is set to 1 following exceptions in Debug state and on any signaled overrun or underrun on the DTR or EDITR.

When this register has an architecturally-defined reset value, this field resets to 0.

STATUS, bits [5:0]

Debug status flags. This field is RO.

The possible values of this field are:

- 000010 PE is in Non-debug state.
- 000001 PE is restarting, exiting Debug state.

000111	Breakpoint.
010011	External debug request.
011011	Halting step, normal.
011111	Halting step, exclusive.
100011	OS Unlock Catch.
100111	Reset Catch.
101011	Watchpoint.
101111	HLT instruction.
110011	Software access to debug register.
110111	Exception Catch.
111011	Halting step, no syndrome.
All other values of STATUS are reserved.	

Accessing the EDSCR:

EDSCR can be accessed through the external debug interface:

Component	Offset
Debug	0x088

H9.2.43 EDVIDSR, External Debug Virtual Context Sample Register

The EDVIDSR characteristics are:

Purpose

Contains sampled values captured on reading [EDPCSR](#)[31:0].

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	Default
Error	Error	Error	RO

Configurations

EDVIDSR is in the Core power domain.

Fields in this register reset to architecturally UNKNOWN values. These apply only on a Cold reset. The register is not affected by a Warm reset and is not affected by an External debug reset.

Implemented only if the OPTIONAL PC Sample-based Profiling Extension is implemented and [ARMv8.2-PCSample](#) is not implemented. If [ARMv8.2-PCSample](#) is implemented, this register is RES0 and the architecture defines the functionality in [PMPCSR](#), [PMCID2SR](#), and [PMVIDSR](#).

If EL2 is not implemented and EL3 is not implemented, it is IMPLEMENTATION DEFINED whether EDVIDSR is implemented.

Attributes

If [ARMv8.1-VHE](#) is implemented, the format of this register differs depending on the value of [EDSCR.SC2](#).

Field descriptions

The EDVIDSR bit assignments are:

When ARMv8.1-VHE is not implemented:

NS, bit [31]

Non-secure state sample. Indicates the Security state associated with the most recent [EDPCSR](#) sample.

If EL3 is not implemented, this bit indicates the Effective value of [SCR.NS](#).

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

E2, bit [30]

Exception level 2 status sample. Indicates whether the most recent [EDPCSR](#) sample was associated with EL2.

If EL2 is not implemented, this bit is RES0.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

E3, bit [29]

Exception level 3 status sample. Indicates whether the most recent **EDPCSR** sample was associated with EL3 using AArch64.

If EDVIDSR.NS == 1 or the PE was in AArch32 state when EDPCSRlo (**EDPCSR**[31:0]) was read, this bit is 0.

If EL3 is not implemented, this bit is RES0.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

HV, bit [28]

EDPCSRhi (**EDPCSR**[63:32]) valid. Indicates whether bits [63:32] of the most recent **EDPCSR** sample might be nonzero:

0 Bits[63:32] of the most recent EDPCSR sample are zero.

1 Bits[63:32] of the most recent EDPCSR sample might be nonzero.

An EDVIDSR.HV value of 1 does not mean that the value of EDPCSRhi is nonzero.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

Bits [27:8]

Reserved, RES0.

VMID, bits [7:0]

VMID sample. The VMID associated with the most recent EDPCSRlo (**EDPCSR**[31:0]) sample.

If the value of EDVIDSR.NS is 0 or the value of EDVIDSR.E2 is 1 this field is RES0.

If EL2 is not implemented, this field is RES0.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

When ARMv8.1-VHE is implemented and EDSCR.SC2 == 0:

NS, bit [31]

Non-secure state sample. Indicates the Security state associated with the most recent **EDPCSR** sample or, when it is read as a single atomic 64-bit read, the current EDPCSR sample.

If EL3 is not implemented, this bit has a fixed read-only value that indicates the Effective value of **SCR.NS**.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

E2, bit [30]

Exception level 2 status sample. Indicates whether the most recent **EDPCSR** sample or, when it is read as a single atomic 64-bit read, the current EDPCSR sample, was associated with EL2.

If EDVIDSR.NS == 0, this bit is 0.

If EL2 is not implemented, this bit is RES0.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

E3, bit [29]

Exception level 3 status sample. Indicates whether the most recent EDPCSR sample or, when it is read as a single atomic 64-bit read, was associated with EL3 using AArch64.

If EDVIDSR.NS == 1 or the PE was in AArch32 state when EDPCSRlo (EDPCSR[31:0]) was read, this bit is 0.

If EL3 is not implemented, this bit is RES0.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

HV, bit [28]

EDPCSRhi (EDPCSR[63:32]) valid. Indicates whether bits [63:32] of the most recent EDPCSR sample might be nonzero:

0 Bits[63:32] of the most recent EDPCSR sample are zero.

1 Bits[63:32] of the most recent EDPCSR sample might be nonzero.

An EDVIDSR.HV value of 1 does not mean that the value of EDPCSRhi is nonzero. An EDVIDSR.HV value of 0 is a hint that EDPCSRhi (EDPCSR[63:32]) does not need to be read.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

Bits [27:16]

Reserved, RES0.

VMID, bits [15:0]

VMID sample. The VMID associated with the most recent EDPCSRlo (EDPCSR[31:0]) sample.

If the value of EDVIDSR.NS is 0 or the value of EDVIDSR.E2 is 1 this field is RES0.

If EL2 is not implemented, then this field is RES0.

If EL2 is implemented and is using AArch64, the VMID is held in VTTBR_EL2.VMID.

If EL2 is implemented and is using AArch32, the VMID is held in VTTBR.VMID.

If 16-bit VMIDs are not supported, EDVIDSR.VMID[15:8] is RES0.

If 16-bit VMIDs are supported, but VTTBRx.VMID[15:8] are not used, EDVIDSR.VMID[15:8] is set to 0.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

When ARMv8.1-VHE is implemented and EDSCR.SC2 == 1:

CONTEXTIDR_EL2, bits [31:0]

Context ID.

- If EL2 is using AArch64, the value of CONTEXTIDR_EL2 as associated with the most recent EDPCSR sample.
- If EDPCSR.NS == 0, then this field is set to an UNKNOWN value.

- Otherwise this field is set to an UNKNOWN value.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

When ARMv8.2-PCSample is implemented:

Bits [31:0]

Reserved, RES0.

Accessing the EDVIDSR:

EDVIDSR can be accessed through the external debug interface:

Component	Offset
Debug	0x0A8

H9.2.44 EDWAR, External Debug Watchpoint Address Register

The EDWAR characteristics are:

Purpose

Returns the virtual data address being accessed when a Watchpoint Debug Event was triggered.

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	Default
Error	Error	Error	RO

Configurations

EDWAR is in the Core power domain. RW fields in this register reset to architecturally UNKNOWN values. These apply only on a Cold reset. The register is not affected by a Warm reset and is not affected by an External debug reset.

Attributes

EDWAR is a 64-bit register.

Field descriptions

The EDWAR bit assignments are:

Bits [63:0]

Watchpoint address. The data virtual address being accessed when a Watchpoint Debug Event was triggered and caused entry to Debug state. This address must be within a naturally-aligned block of memory of power-of-two size no larger than the [DC ZVA](#) block size.

The value of this register is UNKNOWN if the PE is in Non-debug state, or if Debug state was entered other than for a Watchpoint debug event.

The value of EDWAR[63:32] is UNKNOWN if Debug state was entered for a Watchpoint debug event taken from AArch32 state.

The EDWAR is subject to the same alignment rules as the reporting of a watchpointed address in the FAR. See [Determining the memory location that caused a Watchpoint exception on page D2-1948](#)

This field resets to a value that is architecturally UNKNOWN.

Accessing the EDWAR:

EDWAR[31:0] can be accessed through the external debug interface:

Component	Offset
Debug	0x030

EDWAR[63:32] can be accessed through the external debug interface:

Component	Offset
Debug	0x034

H9.2.45 MIDR_EL1, Main ID Register

The MIDR_EL1 characteristics are:

Purpose

Provides identification information for the PE, including an implementer code for the device and a device ID number.

Usage constraints

This register is accessible as follows:

Off	DLK	Default
IMP DEF	IMP DEF	RO

Configurations

External register MIDR_EL1 is architecturally mapped to AArch64 System register [MIDR_EL1](#).

External register MIDR_EL1 is architecturally mapped to AArch32 System register [MIDR](#).

It is IMPLEMENTATION DEFINED whether MIDR_EL1 is implemented in the Core power domain or in the Debug power domain.

Attributes

MIDR_EL1 is a 32-bit register.

Field descriptions

The MIDR_EL1 bit assignments are:

Implementer, bits [31:24]

The Implementer code. This field must hold an implementer code that has been assigned by ARM. Assigned codes include the following:

Hex representation	ASCII representation	Implementer
0x41	A	ARM Limited
0x42	B	Broadcom Corporation
0x43	C	Cavium Inc.
0x44	D	Digital Equipment Corporation
0x49	I	Infineon Technologies AG
0x4D	M	Motorola or Freescale Semiconductor Inc.
0x4E	N	NVIDIA Corporation
0x50	P	Applied Micro Circuits Corporation

Hex representation	ASCII representation	Implementer
0x51	Q	Qualcomm Inc.
0x56	V	Marvell International Ltd.
0x69	i	Intel Corporation

ARM can assign codes that are not published in this manual. All values not assigned by ARM are reserved and must not be used.

Variant, bits [23:20]

An IMPLEMENTATION DEFINED variant number. Typically, this field is used to distinguish between different product variants, or major revisions of a product.

Architecture, bits [19:16]

The permitted values of this field are:

0001	ARMv4
0010	ARMv4T
0011	ARMv5 (obsolete)
0100	ARMv5T
0101	ARMv5TE
0110	ARMv5TEJ
0111	ARMv6
1111	Architectural features are individually identified in the ID_* registers, see Identification registers, functional group on page G4-4727 .

All other values are reserved.

PartNum, bits [15:4]

An IMPLEMENTATION DEFINED primary part number for the device.

On processors implemented by ARM, if the top four bits of the primary part number are 0x0 or 0x7, the variant and architecture are encoded differently.

Revision, bits [3:0]

An IMPLEMENTATION DEFINED revision number for the device.

Accessing the MIDR_EL1:

MIDR_EL1 can be accessed through the external debug interface:

Component	Offset
Debug	0xD00

H9.2.46 OSLAR_EL1, OS Lock Access Register

The OSLAR_EL1 characteristics are:

Purpose

Used to lock or unlock the OS lock.

Usage constraints

This register is accessible as follows:

Off	DLK	EDAD	SLK	Default
Error	Error	IMP DEF	WI	WO

Configurations

External register OSLAR_EL1 is architecturally mapped to AArch64 System register [OSLAR_EL1](#).

External register OSLAR_EL1 is architecturally mapped to AArch32 System register [DBGOSLAR](#).

OSLAR_EL1 is in the Core power domain.

From ARMv8.2, external debug accesses to OSLAR_EL1 are ignored and return an error when any of:

- ExternalInvasiveDebugEnabled() == FALSE.
- ExternalSecureInvasiveDebugEnabled() == FALSE and any of:
 - EL3 is not implemented and the PE is in Secure state.
 - EL3 is implemented and is using AArch64 and [MDCR_EL3.EDAD](#) == 1
 - EL3 is implemented and is using AArch32 and [SDCR.EDAD](#) == 1.

Attributes

OSLAR_EL1 is a 32-bit register.

Field descriptions

The OSLAR_EL1 bit assignments are:

Bits [31:1]

Reserved, RES0.

OSLK, bit [0]

On writes to OSLAR_EL1, bit[0] is copied to the OS lock.

Use [EDPRSR.OSLK](#) to check the current status of the lock.

Accessing the OSLAR_EL1:

OSLAR_EL1 can be accessed through the external debug interface:

Component	Offset
Debug	0x300

H9.3 Cross-Trigger Interface registers

This section lists the Cross-Trigger Interface registers.

H9.3.1 ASICCTL, CTI External Multiplexer Control register

The ASICCTL characteristics are:

Purpose

Can be used to provide IMPLEMENTATION DEFINED controls for the CTI. For example, the register might be used to control multiplexors for additional IMPLEMENTATION DEFINED triggers. The IMPLEMENTATION DEFINED controls provided by this register might modify the architecturally defined behavior of the CTI.

———— **Note** —————

The architecturally-defined triggers must not be multiplexed.

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	EDAD	SLK	Default
IMP DEF	IMP DEF	IMP DEF	IMP DEF	RO	IMP DEF

Configurations

It is IMPLEMENTATION DEFINED whether ASICCTL is implemented in the Core power domain or in the Debug power domain.

If it is implemented in the Core power domain then it is IMPLEMENTATION DEFINED whether it is in the Cold reset domain or the Warm reset domain.

This register must reset to a value that supports the architecturally-defined behavior of the CTI. Changing the value of the register from its reset value causes IMPLEMENTATION DEFINED behavior that might differ from the architecturally-defined behavior of the CTI.

Other than the requirements listed in this register description, all aspects of the reset behavior of the ASICCTL are IMPLEMENTATION DEFINED.

Attributes

ASICCTL is a 32-bit register.

Field descriptions

The ASICCTL bit assignments are:

IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

Accessing the ASICCTL:

ASICCTL can be accessed through the external debug interface:

Component	Offset
CTI	0x144

H9.3.2 CTIAPPCLEAR, CTI Application Trigger Clear register

The CTIAPPCLEAR characteristics are:

Purpose

Clears bits of the Application Trigger register.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	WO

Configurations

CTIAPPCLEAR is in the Debug power domain.

Attributes

CTIAPPCLEAR is a 32-bit register.

Field descriptions

The CTIAPPCLEAR bit assignments are:

APPCLEAR<x>, bit [x], for x = 0 to 31

Application trigger <x> disable.

Bits [31:N] are RAZ/WI. N is the number of ECT channels implemented as defined by the [CTIDEVID.NUMCHAN](#) field.

Writing to this bit has the following effect:

- 0 No effect.
- 1 Clear corresponding bit in CTIAPPTRIG to 0 and clear the corresponding channel event.

If the ECT does not support multicycle channel events, use of CTIAPPCLEAR is deprecated and the debugger must only use [CTIAPPULSE](#).

Accessing the CTIAPPCLEAR:

CTIAPPCLEAR can be accessed through the external debug interface:

Component	Offset
CTI	0x018

H9.3.3 CTIAPPULSE, CTI Application Pulse register

The CTIAPPULSE characteristics are:

Purpose

Causes event pulses to be generated on ECT channels.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	WO

It is CONSTRAINED UNPREDICTABLE whether a write to CTIAPPULSE generates an event on a channel if CTICONTROL.GLBEN is 0.

Configurations

CTIAPPULSE is in the Debug power domain.

Attributes

CTIAPPULSE is a 32-bit register.

Field descriptions

The CTIAPPULSE bit assignments are:

APPULSE<x>, bit [x], for x = 0 to 31

Generate event pulse on ECT channel <x>.

Bits [31:N] are RAZ/WI. N is the number of ECT channels implemented as defined by the CTIDEVID.NUMCHAN field.

Writing to this bit has the following effect:

- 0 No effect.
- 1 Channel <x> event pulse generated.

Note

- The CTIAPPULSE operation does not affect the state of the Application Trigger register, CTIAPPTRIG. If the channel is active, either because of an earlier event or from the application trigger, then the value written to CTIAPPULSE might have no effect.
- Multiple pulse events that occur close together might be merged into a single pulse event.

Accessing the CTIAPPULSE:

CTIAPPULSE can be accessed through the external debug interface:

Component	Offset
CTI	0x01C

H9.3.4 CTIAPPSET, CTI Application Trigger Set register

The CTIAPPSET characteristics are:

Purpose

Sets bits of the Application Trigger register.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RW

Configurations

CTIAPPSET is in the Debug power domain. RW fields in this register reset to architecturally UNKNOWN values. These apply only on an External debug reset. The register is not affected by a Warm reset and is not affected by a Cold reset.

Attributes

CTIAPPSET is a 32-bit register.

Field descriptions

The CTIAPPSET bit assignments are:

APPSET<x>, bit [x], for x = 0 to 31

Application trigger <x> enable.

Bits [31:N] are RAZ/WI. N is the number of ECT channels implemented as defined by the [CTIDEVID.NUMCHAN](#) field.

Possible values of this bit are:

- 0 Reading this means the application trigger is inactive. Writing this has no effect.
- 1 Reading this means the application trigger is active. Writing this sets the corresponding bit in CTIAPPTRIG to 1 and generates a channel event.

If the ECT does not support multicycle channel events, use of CTIAPPSET is deprecated and the debugger must only use [CTIAPPULSE](#).

This field resets to a value that is architecturally UNKNOWN.

Accessing the CTIAPPSET:

CTIAPPSET can be accessed through the external debug interface:

Component	Offset
CTI	0x014

H9.3.5 CTIAUTHSTATUS, CTI Authentication Status register

The CTIAUTHSTATUS characteristics are:

Purpose

Provides information about the state of the IMPLEMENTATION DEFINED authentication interface for CTI.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

CTIAUTHSTATUS is in the Debug power domain.

This register is OPTIONAL, and is required for CoreSight compliance.

Attributes

CTIAUTHSTATUS is a 32-bit register.

Field descriptions

The CTIAUTHSTATUS bit assignments are:

Bits [31:8]

Reserved, RES0.

Bits [7:4]

Reserved, RAZ.

NSNID, bits [3:2]

If EL3 is not implemented and the implemented Security state is Secure state, holds the same value as [DBGAUTHSTATUS_EL1.SNID](#).

Otherwise, holds the same value as [DBGAUTHSTATUS_EL1.NSNID](#).

NSID, bits [1:0]

If EL3 is not implemented and the implemented Security state is Secure state, holds the same value as [DBGAUTHSTATUS_EL1.SID](#).

Otherwise, holds the same value as [DBGAUTHSTATUS_EL1.NSID](#).

Accessing the CTIAUTHSTATUS:

CTIAUTHSTATUS can be accessed through the external debug interface:

Component	Offset
CTI	0xFB8

H9.3.6 CTICHINSTATUS, CTI Channel In Status register

The CTICHINSTATUS characteristics are:

Purpose

Provides the raw status of the ECT channel inputs to the CTI.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

CTICHINSTATUS is in the Debug power domain.

Attributes

CTICHINSTATUS is a 32-bit register.

Field descriptions

The CTICHINSTATUS bit assignments are:

CHIN<n>, bit [n], for n = 0 to 31

Input channel <n> status.

Bits [31:N] are RAZ. N is the number of ECT channels implemented as defined by the [CTIDEVID.NUMCHAN](#) field.

Possible values of this bit are:

0 Input channel <n> is inactive.

1 Input channel <n> is active.

If the ECT channels do not support multicycle events then it is IMPLEMENTATION DEFINED whether an input channel can be observed as active.

Accessing the CTICHINSTATUS:

CTICHINSTATUS can be accessed through the external debug interface:

Component	Offset
CTI	0x138

H9.3.7 CTICHOUTSTATUS, CTI Channel Out Status register

The CTICHOUTSTATUS characteristics are:

Purpose

Provides the status of the ECT channel outputs from the CTI.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

CTICHOUTSTATUS is in the Debug power domain.

Attributes

CTICHOUTSTATUS is a 32-bit register.

Field descriptions

The CTICHOUTSTATUS bit assignments are:

CHOUT<n>, bit [n], for n = 0 to 31

Output channel <n> status.

Bits [31:N] are RAZ. N is the number of ECT channels implemented as defined by the [CTIDEVID.NUMCHAN](#) field.

Possible values of this bit are:

- 0 Output channel <n> is inactive.
- 1 Output channel <n> is active.

If the ECT channels do not support multicycle events then it is IMPLEMENTATION DEFINED whether an input channel can be observed as active.

————— Note —————

The value in CTICHOUTSTATUS is after gating by the channel gate. For more information, see [CTIGATE](#).

Accessing the CTICHOUTSTATUS:

CTICHOUTSTATUS can be accessed through the external debug interface:

Component	Offset
CTI	0x13C

H9.3.8 CTICIDR0, CTI Component Identification Register 0

The CTICIDR0 characteristics are:

Purpose

Provides information to identify a CTI component.

For more information see [About the Component Identification scheme on page K2-6149](#).

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

CTICIDR0 is in the Debug power domain.

Implementation of this register is OPTIONAL.

This register is required for CoreSight compliance.

Attributes

CTICIDR0 is a 32-bit register.

Field descriptions

The CTICIDR0 bit assignments are:

Bits [31:8]

Reserved, RES0.

PRMBL_0, bits [7:0]

Preamble. Must read as 0x0D.

Accessing the CTICIDR0:

CTICIDR0 can be accessed through the external debug interface:

Component	Offset
CTI	0xFF0

H9.3.9 CTICIDR1, CTI Component Identification Register 1

The CTICIDR1 characteristics are:

Purpose

Provides information to identify a CTI component.

For more information see [About the Component Identification scheme on page K2-6149](#).

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

CTICIDR1 is in the Debug power domain.

Implementation of this register is OPTIONAL.

This register is required for CoreSight compliance.

Attributes

CTICIDR1 is a 32-bit register.

Field descriptions

The CTICIDR1 bit assignments are:

Bits [31:8]

Reserved, RES0.

CLASS, bits [7:4]

Component class. Reads as 0x9, debug component.

PRMBL_1, bits [3:0]

Preamble. RAZ.

Accessing the CTICIDR1:

CTICIDR1 can be accessed through the external debug interface:

Component	Offset
CTI	0xFF4

H9.3.10 CTICIDR2, CTI Component Identification Register 2

The CTICIDR2 characteristics are:

Purpose

Provides information to identify a CTI component.

For more information see [About the Component Identification scheme on page K2-6149](#).

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

CTICIDR2 is in the Debug power domain.

Implementation of this register is OPTIONAL.

This register is required for CoreSight compliance.

Attributes

CTICIDR2 is a 32-bit register.

Field descriptions

The CTICIDR2 bit assignments are:

Bits [31:8]

Reserved, RES0.

PRMBL_2, bits [7:0]

Preamble. Must read as 0x05.

Accessing the CTICIDR2:

CTICIDR2 can be accessed through the external debug interface:

Component	Offset
CTI	0xFF8

H9.3.11 CTICIDR3, CTI Component Identification Register 3

The CTICIDR3 characteristics are:

Purpose

Provides information to identify a CTI component.

For more information see [About the Component Identification scheme on page K2-6149](#).

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

CTICIDR3 is in the Debug power domain.

Implementation of this register is OPTIONAL.

This register is required for CoreSight compliance.

Attributes

CTICIDR3 is a 32-bit register.

Field descriptions

The CTICIDR3 bit assignments are:

Bits [31:8]

Reserved, RES0.

PRMBL_3, bits [7:0]

Preamble. Must read as 0xB1.

Accessing the CTICIDR3:

CTICIDR3 can be accessed through the external debug interface:

Component	Offset
CTI	0xFFC

H9.3.12 CTICLAIMCLR, CTI Claim Tag Clear register

The CTICLAIMCLR characteristics are:

Purpose

Used by software to read the values of the CLAIM bits, and to clear these bits to 0.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RW

Configurations

CTICLAIMCLR is in the Debug power domain.

See the CLAIM field description for the effect of an External debug reset on the value returned by this register. This register is not affected by a Warm reset, and is not affected by a Cold reset.

Implementation of this register is OPTIONAL.

Attributes

CTICLAIMCLR is a 32-bit register.

Field descriptions

The CTICLAIMCLR bit assignments are:

CLAIM[x], bit [x], for x = 0 to 31

CLAIM tag clear bit.

For values of x greater than or equal to the IMPLEMENTATION DEFINED number of CLAIM tags, this bit is RAZ/SBZ. Software can rely on these bits reading as zero, and must use a Should-Be-Zero policy on writes. Implementations must ignore writes.

For other values of x, reads return the value of CLAIM[x] and the behavior on writes is:

0 No action.

1 Indirectly clear CLAIM[x] to 0.

A single write to CTICLAIMCLR can clear multiple tags to 0.

An External Debug reset clears the CLAIM tag bits to 0.

Accessing the CTICLAIMCLR:

CTICLAIMCLR can be accessed through the external debug interface:

Component	Offset
CTI	0xFA4

H9.3.13 CTICLAIMSET, CTI Claim Tag Set register

The CTICLAIMSET characteristics are:

Purpose

Used by software to set CLAIM bits to 1.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RW

Configurations

CTICLAIMSET is in the Debug power domain.

Implementation of this register is OPTIONAL.

Attributes

CTICLAIMSET is a 32-bit register.

Field descriptions

The CTICLAIMSET bit assignments are:

CLAIM[x], bit [x], for x = 0 to 31

CLAIM tag set bit.

For values of x greater than or equal to the IMPLEMENTATION DEFINED number of CLAIM tags, this bit is RAZ/SBZ. Software can rely on these bits reading as zero, and must use a Should-Be-Zero policy on writes. Implementations must ignore writes.

For other values of x, the bit is RAO and the behavior on writes is:

0 No action.

1 Indirectly set CLAIM[x] tag to 1.

A single write to CTICLAIMSET can set multiple tags to 1.

An External Debug reset clears the CLAIM tag bits to 0.

Accessing the CTICLAIMSET:

CTICLAIMSET can be accessed through the external debug interface:

Component	Offset
CTI	0xFA0

H9.3.14 CTICONTROL, CTI Control register

The CTICONTROL characteristics are:

Purpose

Controls whether the CTI is enabled.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RW

Configurations

CTICONTROL is in the Debug power domain. Some or all RW fields of this register have defined reset values. These apply only on an External debug reset. The register is not affected by a Warm reset and is not affected by a Cold reset.

Attributes

CTICONTROL is a 32-bit register.

Field descriptions

The CTICONTROL bit assignments are:

Bits [31:1]

Reserved, RES0.

GLBEN, bit [0]

Enables or disables the CTI mapping functions. Possible values of this field are:

0 CTI mapping functions disabled.

1 CTI mapping functions enabled.

When the mapping functions are disabled, no new events are signaled on either output triggers or output channels. If a previously asserted output trigger has not been acknowledged, it remains asserted after the mapping functions are disabled. All output triggers are disabled by CTI reset.

If the ECT supports multicycle channel events any existing output channel events will be terminated.

When this register has an architecturally-defined reset value, this field resets to 0.

Accessing the CTICONTROL:

CTICONTROL can be accessed through the external debug interface:

Component	Offset
CTI	0x000

H9.3.15 CTIDEVAFF0, CTI Device Affinity register 0

The CTIDEVAFF0 characteristics are:

Purpose

Copy of the low half of the PE [MPIDR_EL1](#) register that allows a debugger to determine which PE in a multiprocessor system the CTI component relates to.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

CTIDEVAFF0 is in the Debug power domain.

Implementation of this register is OPTIONAL.

Attributes

CTIDEVAFF0 is a 32-bit register.

Field descriptions

The CTIDEVAFF0 bit assignments are:

Bits [31:0]

[MPIDR_EL1](#) low half. Read-only copy of the low half of [MPIDR_EL1](#), as seen from the highest implemented Exception level.

Accessing the CTIDEVAFF0:

CTIDEVAFF0 can be accessed through the external debug interface:

Component	Offset
CTI	0xFA8

H9.3.16 CTIDEVAFF1, CTI Device Affinity register 1

The CTIDEVAFF1 characteristics are:

Purpose

Copy of the high half of the PE [MPIDR_EL1](#) register that allows a debugger to determine which PE in a multiprocessor system the CTI component relates to.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

CTIDEVAFF1 is in the Debug power domain.
Implementation of this register is OPTIONAL.

Attributes

CTIDEVAFF1 is a 32-bit register.

Field descriptions

The CTIDEVAFF1 bit assignments are:

Bits [31:0]

[MPIDR_EL1](#) high half. Read-only copy of the high half of [MPIDR_EL1](#), as seen from the highest implemented Exception level.

Accessing the CTIDEVAFF1:

CTIDEVAFF1 can be accessed through the external debug interface:

Component	Offset
CTI	0xFAC

H9.3.17 CTIDEVARCH, CTI Device Architecture register

The CTIDEVARCH characteristics are:

Purpose

Identifies the programmers' model architecture of the CTI component.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

CTIDEVARCH is in the Debug power domain.

Implementation of this register is OPTIONAL.

Attributes

CTIDEVARCH is a 32-bit register.

Field descriptions

The CTIDEVARCH bit assignments are:

ARCHITECT, bits [31:21]

Defines the architecture of the component. For CTI, this is ARM Limited.

Bits [31:28] are the JEP106 continuation code, 0x4.

Bits [27:21] are the JEP106 ID code, 0x3B.

PRESENT, bit [20]

When set to 1, indicates that the DEVARCH is present.

This field is 1 in ARMv8.

REVISION, bits [19:16]

Defines the architecture revision. For architectures defined by ARM this is the minor revision.

For CTI, the revision defined by ARMv8 is 0x0.

All other values are reserved.

ARCHID, bits [15:0]

Defines this part to be an ARMv8 debug component. For architectures defined by ARM this is further subdivided.

For CTI:

- Bits [15:12] are the architecture version, 0x1.
- Bits [11:0] are the architecture part number, 0xA14.

This corresponds to CTI architecture version CTIv2.

Accessing the CTIDEVARCH:

CTIDEVARCH can be accessed through the external debug interface:

Component	Offset
CTI	0xFBC

H9.3.18 CTIDEVID, CTI Device ID register 0

The CTIDEVID characteristics are:

Purpose

Describes the CTI component to the debugger.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

CTIDEVID is in the Debug power domain.

Attributes

CTIDEVID is a 32-bit register.

Field descriptions

The CTIDEVID bit assignments are:

Bits [31:26]

Reserved, RES0.

INOUT, bits [25:24]

Input/output options. Indicates presence of the input gate. If the CTM is not implemented, this field is RAZ.

00 **CTIGATE** does not mask propagation of input events from external channels.

01 **CTIGATE** masks propagation of input events from external channels.

All other values are reserved.

Bits [23:22]

Reserved, RES0.

NUMCHAN, bits [21:16]

Number of ECT channels implemented. IMPLEMENTATION DEFINED. For ARMv8, valid values are:

000011 3 channels (0..2) implemented.

000100 4 channels (0..3) implemented.

000101 5 channels (0..4) implemented.

000110 6 channels (0..5) implemented.

and so on up to 100000, 32 channels (0..31) implemented.

All other values are reserved.

Bits [15:14]

Reserved, RES0.

NUMTRIG, bits [13:8]

Number of triggers implemented. IMPLEMENTATION DEFINED. This is one more than the index of the largest trigger, rather than the actual number of triggers.

For ARMv8, valid values are:

000011 Up to 3 triggers (0..2) implemented.

001000 Up to 8 triggers (0..7) implemented.

001001 Up to 9 triggers (0..8) implemented.

001010 Up to 10 triggers (0..9) implemented.

and so on up to 100000, 32 triggers (0..31) implemented.

All other values are reserved. If the contains a Trace extension, this field must be at least 0b001000. There is no guarantee that any of the implemented triggers, including the highest numbered, are connected to any components.

Bits [7:5]

Reserved, RES0.

EXTMUXNUM, bits [4:0]

Number of multiplexors available on triggers. This value is used in conjunction with External Control register, [ASICCTL](#).

Accessing the CTIDEVID:

CTIDEVID can be accessed through the external debug interface:

Component	Offset
CTI	0xFC8

H9.3.19 CTIDEVID1, CTI Device ID register 1

The CTIDEVID1 characteristics are:

Purpose

Reserved for future information about the CTI component to the debugger.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

CTIDEVID1 is in the Debug power domain.

Attributes

CTIDEVID1 is a 32-bit register.

Field descriptions

The CTIDEVID1 bit assignments are:

Bits [31:0]

Reserved, RES0.

Accessing the CTIDEVID1:

CTIDEVID1 can be accessed through the external debug interface:

Component	Offset
CTI	0xFC4

H9.3.20 CTIDEVID2, CTI Device ID register 2

The CTIDEVID2 characteristics are:

Purpose

Reserved for future information about the CTI component to the debugger.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

CTIDEVID2 is in the Debug power domain.

Attributes

CTIDEVID2 is a 32-bit register.

Field descriptions

The CTIDEVID2 bit assignments are:

Bits [31:0]

Reserved, RES0.

Accessing the CTIDEVID2:

CTIDEVID2 can be accessed through the external debug interface:

Component	Offset
CTI	0xFC0

H9.3.21 CTIDEVTYPE, CTI Device Type register

The CTIDEVTYPE characteristics are:

Purpose

Indicates to a debugger that this component is part of a PE's cross-trigger interface.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

CTIDEVTYPE is in the Debug power domain.

Implementation of this register is OPTIONAL.

Attributes

CTIDEVTYPE is a 32-bit register.

Field descriptions

The CTIDEVTYPE bit assignments are:

Bits [31:8]

Reserved, RES0.

SUB, bits [7:4]

Subtype. Must read as 0x1 to indicate this is a component within a PE.

MAJOR, bits [3:0]

Major type. Must read as 0x4 to indicate this is a cross-trigger component.

Accessing the CTIDEVTYPE:

CTIDEVTYPE can be accessed through the external debug interface:

Component	Offset
CTI	0xFCC

H9.3.22 CTIGATE, CTI Channel Gate Enable register

The CTIGATE characteristics are:

Purpose

Determines whether events on channels propagate through the CTM to other ECT components, or from the CTM into the CTI.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RW

Configurations

CTIGATE is in the Debug power domain. RW fields in this register reset to architecturally UNKNOWN values. These apply only on an External debug reset. The register is not affected by a Warm reset and is not affected by a Cold reset.

Attributes

CTIGATE is a 32-bit register.

Field descriptions

The CTIGATE bit assignments are:

GATE<x>, bit [x], for x = 0 to 31

Channel <x> gate enable.

Bits [31:N] are RAZ/WI. N is the number of ECT channels implemented as defined by the [CTIDEVID.NUMCHAN](#) field.

Possible values of this bit are:

- 0 Disable output and, if [CTIDEVID.INOUT](#) == 0b01, input channel <x> propagation.
- 1 Enable output and, if [CTIDEVID.INOUT](#) == 0b01, input channel <x> propagation.

If GATE[x] is set to 0, no new events will be propagated to the ECT, and if the ECT supports multicycle channel events any existing output channel events will be terminated.

This field resets to a value that is architecturally UNKNOWN.

Accessing the CTIGATE:

CTIGATE can be accessed through the external debug interface:

Component	Offset
CTI	0x140

H9.3.23 CTIINEN<n>, CTI Input Trigger to Output Channel Enable registers, n = 0 - 31

The CTIINEN<n> characteristics are:

Purpose

Enables the signaling of an event on output channels when input trigger event n is received by the CTI.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RW

Configurations

CTIINEN<n> is in the Debug power domain. RW fields in this register reset to architecturally UNKNOWN values. These apply only on an External debug reset. The register is not affected by a Warm reset and is not affected by a Cold reset.

If input trigger n is not connected, the behavior of CTIINEN<n> is IMPLEMENTATION DEFINED.

Attributes

CTIINEN<n> is a 32-bit register.

Field descriptions

The CTIINEN<n> bit assignments are:

INEN<x>, bit [x], for x = 0 to 31

Input trigger <n> to output channel <x> enable.

Bits [31:N] are RAZ/WI. N is the number of ECT channels implemented as defined by the CTIDEVID.NUMCHAN field.

Possible values of this bit are:

0 Input trigger <n> will not generate an event on output channel <x>.

1 Input trigger <n> will generate an event on output channel <x>.

This field resets to a value that is architecturally UNKNOWN.

Accessing the CTIINEN<n>:

CTIINEN<n> can be accessed through the external debug interface:

Component	Offset
CTI	0x020 + 4n

H9.3.24 CTIINTACK, CTI Output Trigger Acknowledge register

The CTIINTACK characteristics are:

Purpose

Can be used to deactivate the output triggers.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	WO

A debugger must read [CTITRIGOUTSTATUS](#) to confirm that the output trigger has been acknowledged before generating any event that must be ordered after the write to CTIINTACK, such as a write to CTIAPPULSE to activate another trigger.

Configurations

CTIINTACK is in the Debug power domain.

Attributes

CTIINTACK is a 32-bit register.

Field descriptions

The CTIINTACK bit assignments are:

ACK<n>, bit [n], for n = 0 to 31

Acknowledge for output trigger <n>.

Bits [31:N] are RAZ/WI. N is the number of CTI triggers implemented as defined by the [CTIDEVID.NUMTRIG](#) field.

If any of the following is true, writes to ACK<n> are ignored:

- $n \geq \text{CTIDEVID.NUMTRIG}$, the number of implemented triggers.
- Output trigger n is not active.
- The channel mapping function output, as controlled by [CTIOUTEN<n>](#), is still active.

Otherwise, if any of the following are true, it is IMPLEMENTATION DEFINED whether writes to ACK<n> are ignored:

- Output trigger n is not implemented.
- Output trigger n is not connected.
- Output trigger n is self-acknowledging and does not require software acknowledge.

Otherwise, the behavior on writes to ACK<n> is as follows:

- | | |
|---|-------------------------|
| 0 | No effect |
| 1 | Deactivate the trigger. |

Accessing the CTIINTACK:

CTIINTACK can be accessed through the external debug interface:

Component	Offset
CTI	0x010

H9.3.25 CTIITCTRL, CTI Integration mode Control register

The CTIITCTRL characteristics are:

Purpose

Enables the CTI to switch from its default mode into integration mode, where test software can control directly the inputs and outputs of the PE, for integration testing or topology detection.

Usage constraints

This register is accessible as follows:

Default

RW

Configurations

It is IMPLEMENTATION DEFINED whether CTIITCTRL is implemented in the Core power domain or in the Debug power domain. Some or all RW fields of this register have defined reset values, and:

- The register is not affected by a Warm reset.
- If the register is implemented in the Core power domain the reset values apply on a Cold reset, and the register is not affected by an External debug reset.
- If the register is implemented in the Debug power domain the reset values apply on an External debug reset, and the register is not affected by a Cold reset.

Implementation of this register is OPTIONAL.

Attributes

CTIITCTRL is a 32-bit register.

Field descriptions

The CTIITCTRL bit assignments are:

Bits [31:1]

Reserved, RES0.

IME, bit [0]

Integration mode enable. When IME == 1, the device reverts to an integration mode to enable integration testing or topology detection. The integration mode behavior is IMPLEMENTATION DEFINED.

0 Normal operation.

1 Integration mode enabled.

When this register has an architecturally-defined reset value, this field resets to 0.

Accessing the CTIITCTRL:

CTIITCTRL can be accessed through the external debug interface:

Component	Offset
CTI	0xF00

H9.3.26 CTILAR, CTI Lock Access Register

The CTILAR characteristics are:

Purpose

Allows or disallows access to the CTI registers through a memory-mapped interface.

Usage constraints

This register is accessible as follows:

Default

WO

Configurations

CTILAR is in the Debug power domain.

If OPTIONAL memory-mapped access to the external debug interface is supported then an OPTIONAL Software Lock can be implemented as part of CoreSight compliance.

CTILAR ignores writes if the Software lock is not implemented and ignores writes for other accesses to the external debug interface.

The Software Lock provides a lock to prevent memory-mapped writes to the Cross-Trigger Interface registers. Use of this lock mechanism reduces the risk of accidental damage to the contents of the Cross-Trigger Interface registers. It does not, and cannot, prevent all accidental or malicious damage.

Software uses CTILAR to set or clear the lock, and CTILSR to check the current status of the lock.

Attributes

CTILAR is a 32-bit register.

Field descriptions

The CTILAR bit assignments are:

KEY, bits [31:0]

Lock Access control. Writing the key value 0xC5ACCE55 to this field unlocks the lock, enabling write accesses to this component's registers through a memory-mapped interface.

Writing any other value to this register locks the lock, disabling write accesses to this component's registers through a memory mapped interface.

Accessing the CTILAR:

CTILAR can be accessed through a memory-mapped interface access to the external debug interface:

Component	Offset
CTI	0xFB0

H9.3.27 CTILSR, CTI Lock Status Register

The CTILSR characteristics are:

Purpose

Indicates the current status of the Software Lock for CTI registers.

Usage constraints

This register is accessible as follows:

Default
RO

Configurations

CTILSR is in the Debug power domain. Some or all RW fields of this register have defined reset values. These apply only on an External debug reset. The register is not affected by a Warm reset and is not affected by a Cold reset.

If OPTIONAL memory-mapped access to the external debug interface is supported then an OPTIONAL Software Lock can be implemented as part of CoreSight compliance.

CTILSR is RAZ if the Software Lock is not implemented and is RAZ for other accesses to the external debug interface.

The Software Lock provides a lock to prevent memory-mapped writes to the Cross-Trigger Interface registers. Use of this lock mechanism reduces the risk of accidental damage to the contents of the Cross-Trigger Interface registers. It does not, and cannot, prevent all accidental or malicious damage.

Software uses [CTILAR](#) to set or clear the lock, and CTILSR to check the current status of the lock.

Attributes

CTILSR is a 32-bit register.

Field descriptions

The CTILSR bit assignments are:

Bits [31:3]

Reserved, RES0.

nTT, bit [2]

Not thirty-two bit access required. RAZ.

SLK, bit [1]

Software Lock status for this component. For an access to LSR that is not a memory-mapped access, or when the Software Lock is not implemented, this field is RES0.

For memory-mapped accesses when the Software Lock is implemented, possible values of this field are:

- 0 Lock clear. Writes are permitted to this component's registers.
- 1 Lock set. Writes to this component's registers are ignored, and reads have no side effects.

When this register has an architecturally-defined reset value, this field resets to 1.

SLI, bit [0]

Software Lock implemented. For an access to LSR that is not a memory-mapped access, this field is RAZ. For memory-mapped accesses, the value of this field is IMPLEMENTATION DEFINED.

Permitted values are:

- 0 Software Lock not implemented or not memory-mapped access.
- 1 Software Lock implemented and memory-mapped access.

Accessing the CTILSR:

CTILSR can be accessed through a memory-mapped interface access to the external debug interface:

Component	Offset
CTI	0xFB4

H9.3.28 CTIOUTEN<n>, CTI Input Channel to Output Trigger Enable registers, n = 0 - 31

The CTIOUTEN<n> characteristics are:

Purpose

Defines which input channels generate output trigger n.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RW

Configurations

CTIOUTEN<n> is in the Debug power domain. RW fields in this register reset to architecturally UNKNOWN values. These apply only on an External debug reset. The register is not affected by a Warm reset and is not affected by a Cold reset.

If output trigger n is not connected, the behavior of CTIOUTEN<n> is IMPLEMENTATION DEFINED.

Attributes

CTIOUTEN<n> is a 32-bit register.

Field descriptions

The CTIOUTEN<n> bit assignments are:

OUTEN<x>, bit [x], for x = 0 to 31

Input channel <x> to output trigger <n> enable.

Bits [31:N] are RAZ/WI. N is the number of ECT channels implemented as defined by the CTIDEVID.NUMCHAN field.

Possible values of this bit are:

- 0 An event on input channel <x> will not cause output trigger <n> to be asserted.
- 1 An event on input channel <x> will cause output trigger <n> to be asserted.

This field resets to a value that is architecturally UNKNOWN.

Accessing the CTIOUTEN<n>:

CTIOUTEN<n> can be accessed through the external debug interface:

Component	Offset
CTI	0x0A0 + 4n

H9.3.29 CTIPIDR0, CTI Peripheral Identification Register 0

The CTIPIDR0 characteristics are:

Purpose

Provides information to identify a CTI component.

For more information see [About the Peripheral identification scheme on page K2-6146](#).

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

CTIPIDR0 is in the Debug power domain.

Implementation of this register is OPTIONAL.

This register is required for CoreSight compliance.

Attributes

CTIPIDR0 is a 32-bit register.

Field descriptions

The CTIPIDR0 bit assignments are:

Bits [31:8]

Reserved, RES0.

PART_0, bits [7:0]

Part number, least significant byte.

Accessing the CTIPIDR0:

CTIPIDR0 can be accessed through the external debug interface:

Component	Offset
CTI	0xFE0

H9.3.30 CTIPIDR1, CTI Peripheral Identification Register 1

The CTIPIDR1 characteristics are:

Purpose

Provides information to identify a CTI component.

For more information see [About the Peripheral identification scheme on page K2-6146](#).

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

CTIPIDR1 is in the Debug power domain.

Implementation of this register is OPTIONAL.

This register is required for CoreSight compliance.

Attributes

CTIPIDR1 is a 32-bit register.

Field descriptions

The CTIPIDR1 bit assignments are:

Bits [31:8]

Reserved, RES0.

DES_0, bits [7:4]

Designer, least significant nibble of JEP106 ID code. For ARM Limited, this field is 0b1011.

PART_1, bits [3:0]

Part number, most significant nibble.

Accessing the CTIPIDR1:

CTIPIDR1 can be accessed through the external debug interface:

Component	Offset
CTI	0xFE4

H9.3.31 CTIPIDR2, CTI Peripheral Identification Register 2

The CTIPIDR2 characteristics are:

Purpose

Provides information to identify a CTI component.

For more information see [About the Peripheral identification scheme on page K2-6146](#).

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

CTIPIDR2 is in the Debug power domain.

Implementation of this register is OPTIONAL.

This register is required for CoreSight compliance.

Attributes

CTIPIDR2 is a 32-bit register.

Field descriptions

The CTIPIDR2 bit assignments are:

Bits [31:8]

Reserved, RES0.

REVISION, bits [7:4]

Part major revision. Parts can also use this field to extend Part number to 16-bits.

JEDEC, bit [3]

RAO. Indicates a JEP106 identity code is used.

DES_1, bits [2:0]

Designer, most significant bits of JEP106 ID code. For ARM Limited, this field is 0b011.

Accessing the CTIPIDR2:

CTIPIDR2 can be accessed through the external debug interface:

Component	Offset
CTI	0xFE8

H9.3.32 CTIPIDR3, CTI Peripheral Identification Register 3

The CTIPIDR3 characteristics are:

Purpose

Provides information to identify a CTI component.

For more information see [About the Peripheral identification scheme on page K2-6146](#).

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

CTIPIDR3 is in the Debug power domain.

Implementation of this register is OPTIONAL.

This register is required for CoreSight compliance.

Attributes

CTIPIDR3 is a 32-bit register.

Field descriptions

The CTIPIDR3 bit assignments are:

Bits [31:8]

Reserved, RES0.

REVAND, bits [7:4]

Part minor revision. Parts using [CTIPIDR2.REVISION](#) as an extension to the Part number must use this field as a major revision number.

CMOD, bits [3:0]

Customer modified. Indicates someone other than the Designer has modified the component.

Accessing the CTIPIDR3:

CTIPIDR3 can be accessed through the external debug interface:

Component	Offset
CTI	0xFEC

H9.3.33 CTIPIDR4, CTI Peripheral Identification Register 4

The CTIPIDR4 characteristics are:

Purpose

Provides information to identify a CTI component.

For more information see [About the Peripheral identification scheme on page K2-6146](#).

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

CTIPIDR4 is in the Debug power domain.

Implementation of this register is OPTIONAL.

This register is required for CoreSight compliance.

Attributes

CTIPIDR4 is a 32-bit register.

Field descriptions

The CTIPIDR4 bit assignments are:

Bits [31:8]

Reserved, RES0.

SIZE, bits [7:4]

Size of the component. RAZ. \log_2 of the number of 4KB pages from the start of the component to the end of the component ID registers.

DES_2, bits [3:0]

Designer, JEP106 continuation code, least significant nibble. For ARM Limited, this field is 0b0100.

Accessing the CTIPIDR4:

CTIPIDR4 can be accessed through the external debug interface:

Component	Offset
CTI	0xFD0

H9.3.34 CTITRIGINSTATUS, CTI Trigger In Status register

The CTITRIGINSTATUS characteristics are:

Purpose

Provides the status of the trigger inputs.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

CTITRIGINSTATUS is in the Debug power domain.

Attributes

CTITRIGINSTATUS is a 32-bit register.

Field descriptions

The CTITRIGINSTATUS bit assignments are:

TRIN<n>, bit [n], for n = 0 to 31

Trigger input <n> status.

Bits [31:N] are RAZ. N is the number of CTI triggers implemented as defined by the [CTIDEVID.NUMTRIG](#) field.

Possible values of this bit are:

- 0 Input trigger n is inactive.
- 1 Input trigger n is active.

Not implemented and not-connected input triggers are always inactive.

It is IMPLEMENTATION DEFINED whether an input trigger that does not support multicyle events can be observed as active.

Accessing the CTITRIGINSTATUS:

CTITRIGINSTATUS can be accessed through the external debug interface:

Component	Offset
CTI	0x130

H9.3.35 CTITRIGOUTSTATUS, CTI Trigger Out Status register

The CTITRIGOUTSTATUS characteristics are:

Purpose

Provides the raw status of the trigger outputs, after processing by any IMPLEMENTATION DEFINED trigger interface logic. For output triggers that are self-acknowledging, this is only meaningful if the CTI implements multicycle channel events.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

CTITRIGOUTSTATUS is in the Debug power domain.

Attributes

CTITRIGOUTSTATUS is a 32-bit register.

Field descriptions

The CTITRIGOUTSTATUS bit assignments are:

TROUT<n>, bit [n], for n = 0 to 31

Trigger output <n> status.

Bits [31:N] are RAZ, where N is the value of the CTIDEVID.NUMTRIG field.

If $n < N$, and output trigger <n> is implemented and connected, and either the trigger is not self-acknowledging or the CTI implements multicycle channel events, then permitted values for TROUT<n> are:

- 0 Output trigger n is inactive.
- 1 Output trigger n is active.

Otherwise when $n < N$ it is IMPLEMENTATION DEFINED whether TROUT<n> behaves as described here or is RAZ.

Accessing the CTITRIGOUTSTATUS:

CTITRIGOUTSTATUS can be accessed through the external debug interface:

Component	Offset
CTI	0x134

Part I

Memory-mapped Components of the ARMv8 Architecture

Chapter I1

System Level Implementation of the Generic Timer

This chapter defines the system level implementation of the Generic Timer. It contains the following sections:

- [About the Generic Timer specification on page I1-5724.](#)
- [Memory-mapped counter module on page I1-5726.](#)
- [Memory-mapped timer components on page I1-5730.](#)
- [Providing a complete set of counter and timer features on page I1-5734.](#)
- [Gray-count scheme for timer distribution scheme on page I1-5736.](#)

Note

- [Generic Timer memory-mapped register descriptions on page I3-5816](#) describes the System level Generic Timer registers. These registers are memory-mapped.
 - [Chapter D6 The Generic Timer in AArch64 state](#) gives a general description of the AArch64 state view of the Generic Timer, and describes the AArch64 System register interface to the Generic Timer.
 - [Chapter G5 The Generic Timer in AArch32 state](#) gives a general description of the AArch32 state view of the Generic Timer, and describes the AArch32 System register interface to the Generic Timer.
-

I1.1 About the Generic Timer specification

[Chapter D6 The Generic Timer in AArch64 state](#) describes the ARM Generic Timer and its implementation as seen from AArch64 state. [Chapter G5 The Generic Timer in AArch32 state](#) describes the ARM Generic Timer and its implementation as seen from AArch32 state. These chapters include the definition of the low-latency System register interface to the Generic Timer. However, the ARM Generic Timer architecture also defines a memory-mapped component, that comprises:

- A memory-mapped counter module, that controls the generation of the Count value used by the Generic Timer.
This memory-mapped counter module is required in any ARM Generic Timer implementation that requires software control of the Count value of the Generic Timer.
- Optional memory-mapped timer modules. These give a standardized way of providing timers for programmable system components other than PEs that implement the ARM architecture.

[The full set of Generic Timer components on page D6-2181](#) summarizes these components as seen from AArch64 state, and [The full set of Generic Timer components on page G5-4753](#) summarizes them as seen from AArch32 state. [The system level components of the Generic Timer on page I1-5725](#) summarizes the system level components.

I1.1.1 Registers in the system level implementation of the Generic Timer

Registers that control components of the system level implementation of the Generic Timer are grouped into *frames*. This specification defines the registers in each frame, and their offsets within the frame. The system defines the position of each frame in the memory map. This means the base addresses for each frame is IMPLEMENTATION DEFINED.

———— **Note** —————

The final twelve words of the first or only 4KB block of a register memory frame is an ID block.

All memory-mapped peripherals defined in the ARM architecture must be little-endian. This means the system-level Generic Timer registers, and the register frames, are little-endian.

Power and reset domains for the system level implementation of the Generic Timer

The power and reset domains of the system level implementation of the Generic Timer are IMPLEMENTATION DEFINED as part of the system implementation. These domains can be outside the PE power and reset domains defined by the remainder of this manual.

The ARM architecture requires that the `CNTCR`.{FCREQ, EN} and `CNTSR`.FCACK fields reset to 0. These reset values apply only on powerup of the power domain in which the registers are implemented or a reset of the reset domain in which they are implemented.

Every other register, or register field, of a system level implementation of the Generic Timer resets to a value that is architecturally UNKNOWN if it has a meaningful reset value. This applies on powerup of the power domain in which the register is implemented, and on a reset of the reset domain in which it is implemented.

I1.1.2 The system level components of the Generic Timer

Each system level component has one or two register frames. The possible system level components are:

The memory-mapped counter module, required

This module controls the system counter. It has two frames:

- A control frame, [CNTControlBase](#).
- A status frame, [CNTReadBase](#).

[Memory-mapped counter module on page I1-5726](#) describes this component.

The memory-mapped timer control module, required

The system level implementation of the Generic Timer can provide up to eight timers, and the memory-mapped timer control module identifies:

- Which timers are implemented.
- The features of each implemented timer.

This module has a single frame, [CNTCTLBase](#).

[The CNTCTLBase frame on page I1-5731](#) describes this frame.

Memory-mapped timers, optional

An implemented memory-mapped timer:

- Must provide a privileged view of the timer, in the [CNTBaseN](#) frame.
- Optionally provides an unprivileged view of the timer in the [CNTELOBaseN](#) frame.

N is the timer number, and the corresponding frame number, in the range 0-7.

[The CNTBaseN and CNTELOBaseN frames on page I1-5732](#) describes these frames.

I1.2 Memory-mapped counter module

The memory-mapped counter module provides top-level control of the system counter. The [CNTControlBase](#) frame holds the registers for the memory-mapped counter, and provides:

- A RW control register [CNTCR](#), that provides:
 - An enable bit for the system counter.
 - An enable bit for Halt-on-Debug. When this is enabled, if the debug halt signal into the system counter is asserted, it halts the system counter. Otherwise, the system counter ignores the state of this halt signal. For more information about Halt-on-Debug, contact ARM.
 - A field that can be written to request a change to the update frequency of the system counter, with a corresponding change to the increment made at each update. This mechanism means that, for example, if the update frequency is halved, the increment at each update is doubled.
For more information see [Control of counter operating frequency and increment on page I1-5727](#).

Writes to this register are rare. In a system that supports two Security states, this register is writable only by Secure writes.

- A RO status register, [CNTSR](#), that provides:
 - A bit that indicates whether the system counter is halted because of an asserted Halt-on-Debug signal.
 - A field that indicates the current update frequency of the system counter. This field can be polled to determine when a requested change to the update frequency has been made.

- Two contiguous 32-bit RW registers that hold the current system counter value, [CNTCV](#). If the system supports 64-bit atomic accesses, these two registers must be accessible by such accesses.

The system counter must be disabled before writing to these registers, otherwise the effect of the write is UNPREDICTABLE.

Writes to these registers are rare. In a system that supports two Security states, these registers are writable only by Secure writes.

- A *Frequency modes table* of one or more 32-bit entries, where:
 - The first entry in the table defines the *base frequency* of the system counter. This is the maximum frequency at which the counter updates.
 - Each subsequent entry in the table defines an alternative frequency of the system counter, that must be an exact divisor of the base frequency.

A 32-bit zero entry immediately follows the last table entry.

This table can be RO or RW. For more information, see [The Frequency modes table on page I1-5727](#).

In addition, the [CNTReadBase](#) frame includes a read-only copy of the system counter value, [CNTCV](#), as two contiguous 32-bit RO registers. If the system supports 64-bit atomic accesses, these two registers must be accessible by such accesses.

[Counter module control and status register summary on page I1-5728](#) describes [CNTReadBase](#) and [CNTControlBase](#) memory maps, and the registers in each frame.

I1.2.1 Control of counter operating frequency and increment

The system counter has a fixed *base frequency*, and must maintain the required counter accuracy, meaning ARM recommends that it does not gain or lose more than ten seconds in a 24-hour period, see [The system counter on page D6-2182](#). However, the counter can increment at a lower frequency than the base frequency, using a correspondingly larger increment. For example, it can increment by four at a quarter of the base frequency. Any lower-frequency operation, and any switching between operating frequencies, must not reduce the accuracy of the counter.

Control of the system counter frequency and increment is provided only through the memory-mapped counter module. The following sections describe this control:

- [The Frequency modes table](#).
- [Changing the system counter and increment](#).

The Frequency modes table

The Frequency modes table starts at offset 0x20 in the [CNTControlBase](#) frame.

Table entries are 32-bits, and each entry specifies a system counter update frequency, in Hz.

The first entry in the table specifies the base frequency of the system counter.

When the system timer is operating at a lower frequency than the base frequency, the increment applied at each counter update is given by:

$$\text{increment} = (\text{base_frequency}) / (\text{selected_frequency})$$

A 32-bit word of zero value marks the end of the table. That is, the word of memory immediately after the last entry in the table must be zero.

The only required entry in the table is the entry for the base frequency.

Typically, the Frequency modes table is in RO memory. However, a system implementation might use RW memory for the table, and initialize the table entries as part of its startup sequence. Therefore, the [CNTControlBase](#) memory map shows the table region as RO or RW.

ARM strongly recommends that the Frequency modes table is not updated once the system is running.

The architecture can support up to 1004 entries in the Frequency modes table, including the zero-word end marker, and the maximum number of entries is IMPLEMENTATION DEFINED, up to this limit.

————— **Note** —————

- ARM considers it likely that implementations will require significantly fewer entries than the architectural limit.
- In the [CNTControlBase](#) frame, the offset range 0x0C0-0x0FC can be used for IMPLEMENTATION DEFINED registers. If any registers are defined in this space then the Frequency modes table cannot extend beyond offset 0x0B8, with a zero word at offset 0x0BC. This means the maximum number of entries in the table is 40, including the zero-word end marker.

Changing the system counter and increment

The value of the [CNTCR.FCREQ](#) field specifies which entry in the Frequency modes table specifies the system counter update frequency.

Changing the value of [CNTCR.FCREQ](#) requests a change to the system counter update frequency. To ensure the frequency change does not affect the overall accuracy of the counter, a change is made as follows:

- When changing from a higher frequency to a lower frequency, the counter:
 1. Continues running at the higher frequency until the count reaches an integer multiple of the required lower frequency.
 2. Switches to operating at the lower frequency.

- When changing from a lower frequency to a higher frequency, the counter:
 1. Waits until the end of the current lower-frequency cycle.
 2. Makes the counter increment required for operation at that lower frequency.
 3. Switches to operating at the higher frequency.

When the frequency has changed, [CNTSR](#) is updated to indicate the new frequency. Therefore, a system component that is waiting for a frequency change can poll [CNTSR](#) to detect the change.

11.2.2 Counter module control and status register summary

The Counter module control and status registers are memory-mapped registers in the following register memory frames:

- A control frame, with base address [CNTControlBase](#).
- A status frame, with base address [CNTReadBase](#).

Each of these register memory frames is at least 4KB in size, or is at least the size of the memory protection granule if this granule size is larger than 4KB. Similarly, each base address must be aligned to 4KB, or to the memory protection granule if that is larger than 4KB.

———— **Note** —————

- The memory protection granule is either 4KB, 16KB or 64KB.
- Each frame of a memory-mapped Generic Timer takes the name of its base address.

In each register memory frame, the memory at offset 0xFD0-0xFFF is reserved for twelve 32-bit IMPLEMENTATION DEFINED ID registers, see the [CounterID<n>](#) register descriptions for more information.

———— **Note** —————

The ARM architecture requires memory-mapped peripherals to be little-endian, and therefore the counter is little-endian.

In an implementation that supports Secure and Non-secure memory maps, [CNTControlBase](#) is implemented only in the Secure memory map.

[Table I1-1](#) shows the [CNTControlBase](#) control registers, in order of their offsets from the [CNTControlBase](#) base address, for an implementation that includes registers in the implementation defined register space 0x0C0-0x0FC, and also has fewer than 39 [CNTFID<n>](#) registers. [The Frequency modes table on page I1-5727](#) describes how this memory map differs if more [CNTFID<n>](#) registers are implemented.

[Generic Timer memory-mapped register descriptions on page I3-5816](#) describes each of these registers.

Table I1-1 CNTControlBase memory map

Offset	Name	Type	Description
0x000	CNTCR	RW	Counter Control Register.
0x004	CNTSR	RO	Counter Status Register.
0x008	CNTCV[31:0]	RW	Counter Count Value register.
0x00C	CNTCV[63:32]	RW	
0x010-0x01C	-	RES0	Reserved.
0x020	CNTFID0	RO or RW	Frequency modes table, and end marker.
0x020+4n	CNTFID<n>	RO or RW	For more information see The Frequency modes table on page I1-5727 .
0x024+4n	-	RO or RW, RAZ	

Table 11-1 CNTControlBase memory map (continued)

Offset	Name	Type	Description
(0x028+4n)-0x0BC	-	RO, RES0	Reserved.
0x0C0-0x0FC	-	IMPLEMENTATION DEFINED	Reserved for IMPLEMENTATION DEFINED registers.
0x100-0xFCC	-	RO, RES0	Reserved.
0xFD0-0xFFC	CounterID<n>	RO	Counter ID registers 0-11.

Table 11-2 shows the CNTReadBase control registers, in order of their offsets from the CNTReadBase base address. *Generic Timer memory-mapped register descriptions on page 13-5816* describes each of these registers.

Table 11-2 CNTReadBase memory map

Offset	Name	Type	Description
0x000	CNTCV[31:0]	RO	Counter Count Value register
0x004	CNTCV[63:32]	RO	
0x008-0xFCC	-	RES0	Reserved
0xFD0-0xFFC	CounterID<n>	RO	Counter ID registers 0-11

I1.3 Memory-mapped timer components

This part of the ARM Generic Timer specification defines an optional memory-mapped timer component. This can be implemented as part of any programmable system component that does not incorporate a System register mapped ARM Generic Timer, to provide that system component with the timer functionality of an ARM Generic Timer.

The memory map consists of up to 8 timer *frames*. Each timer frame:

- Provides its own set of timers and associated interrupts.
- Is in its own memory protection region that is:
 - In its own memory protection region, with a system-defined size of 4KB, 16KB or 64KB.
 - At a start address that is aligned to 4KB.

———— **Note** —————

The start address 4KB alignment requirement applies regardless of the memory protection region size.

The base address of a frame is `CNTBaseN`, where *N* numbers from 0 up to a maximum permitted value of 7.

For each implemented `CNTBaseN` frame the system can optionally provide an unprivileged view of the frame, described as the EL0 view of the frame. The base address of this second view of the `CNTBaseN` frame is `CNTELOBaseN`.

———— **Note** —————

In the naming of the registers associated with a `CNTBaseN` or `CNTELOBaseN` frame, the value of *N* is represented as `<n>`, for example `CNTACR<n>`.

If a `CNTELOBaseN` frame is implemented:

- All registers visible in `CNTBaseN` can be visible, except for `CNTVOFF` and `CNTELOACR`.
 - Control fields in `CNTELOACR` determine whether the registers are visible.
- The offsets of all visible registers are the same as their offsets in the `CNTBaseN` frame.

In addition to the implemented `CNTBaseN` and `CNTELOBaseN` frames, the system must provide a single control frame at base address `CNTCTLBase`.

The memory protection region and alignment requirements for the `CNTELOBaseN` and `CNTCTLBase` frames are the same as the requirements for the `CNTBaseN` frames.

The system defines the position of each frame in the memory map. This means the values of each of the `CNTBaseN`, `CNTELOBaseN`, and `CNTCTLBase` base addresses is IMPLEMENTATION DEFINED.

———— **Note** —————

The ARM architecture requires memory-mapped peripherals to be little-endian, and therefore the memory-mapped timers are little-endian.

The following sections describe the implementation of a memory-mapped view of the counter and timer:

- [The `CNTCTLBase` frame on page I1-5731.](#)
- [The `CNTBaseN` and `CNTELOBaseN` frames on page I1-5732.](#)
- [Providing a complete set of counter and timer features on page I1-5734.](#)

I1.3.1 The CNTCTLBase frame

The CNTCTLBase frame contains:

- An identification register for the features of the memory-mapped counter and timer implementation.
- Access controls for each CNTBaseN frame.
- A virtual offset register for frames that implement a virtual timer.

Table I1-3 shows the CNTCTLBase registers, in order of their offsets from the CNTCTLBase base address.

———— **Note** ————

CNTFRQ and CNTVOFF registers are also implemented in a System register interface to the Generic Timer.

Generic Timer memory-mapped register descriptions on page I3-5816 describes each of these registers.

Table I1-3 CNTCTLBase memory map

Offset	Register	Type	Security ^a	Description
0x000	CNTFRQ ^b	RW	Secure	Counter Frequency register.
0x004	CNTNSAR	RW	Secure	Counter Non-Secure Access register.
0x008	CNTTIDR	RO	Both	Counter Timer ID register.
0x00C- 0x03F	-	RES0	-	Reserved.
0x040+4N ^c	CNTACR<n>	RW	Configurable ^d	Counter Access Control register N.
0x060- 0x07F	-	RES0	-	Reserved.
0x080+8N ^c	CNTVOFF<n>[31:0] ^b	RW ^e	Configurable ^d	Virtual Offset register N. If the CNTBaseN frame has virtual timer capability then CNTVOFF is implemented as a RW register, otherwise its location is RAZ/WI.
0x084+8N ^c	CNTVOFF<n>[63:32] ^b	RW ^e		
0x0C0-0x0FC	-	RES0	-	Reserved.
0x100-0x7FC	-	-	-	IMPLEMENTATION DEFINED.
0x800-0xFBC	-	RES0	-	Reserved.
0xFC0-0xFCF	-	-	-	IMPLEMENTATION DEFINED.
0xFD0- 0xFFC	CounterID<n>	RO	Both	Counter ID registers 0-11.

- Access security requirement in an implementation that supports two Security states. In an implementation that does not support multiple Security states all registers are accessible as shown in the *Type* column.
- These registers are also defined in the System register interface to the Generic Timer, and therefore are also described in *Generic Timer registers on page D7-2672* and *Generic Timer registers on page G6-5383*. The bit assignments of the registers are identical in the System register interface and in the memory-mapped system level interface.
- Implemented for each value of N from 0 to 7 for which a CNTBaseN frame is implemented.
- The CNTNSAR determines the Non-secure accessibility of the CNTACR<n>s and the CNTVOFF<n>s in the CNTCTLBase frame. For more information, see the register descriptions.
- Address is reserved, RAZ/WI if register not implemented.

All implementations of the Generic Timer include the virtual counter. Therefore, conceptually, all implementations include the CNTVOFF register that defines the virtual offset between the physical count and the virtual count. If a memory-mapped Generic Timer component does not distinguish between real time and virtual time then it can implement CNTVOFF as RAZ/WI. Otherwise CNTVOFF is a RW register, and ARM strongly recommends that the system only permits access to CNTVOFF from EL2 or higher.

11.3.2 The CNTBaseN and CNTEL0BaseN frames

Each CNTBaseN frame, or {CNTBaseN, CNTEL0BaseN} pair of frames, provides a memory-mapped counter and timer, see:

- [The CNTBaseN frame.](#)
- [The CNTEL0BaseN frame on page I1-5733.](#)
- [CNTCTLBase status and control fields for the CNTBaseN and CNTEL0BaseN frames on page I1-5733.](#)

The CNTBaseN frame

Table I1-4 shows the CNTBaseN registers, in order of their offsets from the CNTBaseN base address. Whether a frame includes a virtual timer is IMPLEMENTATION DEFINED. If it does not then memory at offsets 0x030-0x03C is RAZ/WI. Except for CNTEL0ACR and the CounterID<n> registers, equivalent registers are also implemented in a System register interface to the timer component of a Generic Timer.

[Generic Timer memory-mapped register descriptions on page I3-5816](#) describes each of these registers.

Table I1-4 CNTBaseN memory map

Offset	Register	Type	Description
0x000	CNTPCT[31:0] ^a	RO	Physical Count register.
0x004	CNTPCT[63:32] ^a	RO	
0x008	CNTVCT[31:0] ^a	RO	Virtual Count register.
0x00C	CNTVCT[63:32] ^a	RO	
0x010	CNTFRQ ^a	RO ^c	Counter Frequency register.
0x014	CNTEL0ACR	RW ^b	Counter EL0 Access Control Register, optional in the CNTBaseN memory map.
0x018	CNTVOFF[31:0] ^a	RO ^c	Virtual Offset register. If CNTVOFF<n> in the CNTCTLBase frame is a RW register, a read of this register returns the value of that register.
0x01C	CNTVOFF[63:32] ^a	RO ^c	Otherwise is RAZ.
0x020	CNTP_CVAL[31:0] ^a	RW	Physical Timer CompareValue register.
0x024	CNTP_CVAL[63:32] ^a	RW	
0x028	CNTP_TVAL ^a	RW	Physical TimerValue register.
0x02C	CNTP_CTL ^a	RW	Physical Timer Control register.
0x030	CNTV_CVAL[31:0] ^a	RW ^b	Virtual Timer CompareValue register, optional in the CNTBaseN memory map.
0x034	CNTV_CVAL[63:32] ^a	RW ^b	
0x038	CNTV_TVAL ^a	RW ^b	Virtual TimerValue register, optional in the CNTBaseN memory map.
0x03C	CNTV_CTL ^a	RW ^b	Virtual Timer Control register, optional in the CNTBaseN memory map.
0x040-0xFCF	-	RES0	Reserved.
0xFD0-0xFFC	CounterID<n>	RO	Counter ID registers 0-11.

a. These registers are also defined in the System register interface to the Generic Timer, and therefore are also described in [Generic Timer registers on page D7-2672](#) and [Generic Timer registers on page G6-5383](#). The bit assignments of the registers are identical in the System register interface and in the memory-mapped system level interface.

b. Address is reserved, RAZ/WI if register not implemented

c. The CNTCTLBase frame includes a RW view of this register.

The CNTEL0BaseN frame

For any value of N , the layout of the registers in the CNTEL0BaseN frame is identical to the CNTBaseN frame, except that, in the CNTEL0BaseN frame:

- CNTVOFF is never visible, and the memory at 0x018-0x01C is RAZ/WI.
- CNTEL0ACR is never visible, and the memory at 0x014 is RAZ/WI.
- If implemented in the CNTBaseN frame, CNTEL0ACR controls whether CNTPCT, CNTVCT, CNTFRQ, the Physical Timer, and the Virtual Timer registers are visible in the CNTEL0BaseN frame.
If CNTEL0ACR is not implemented then these registers are not visible in the CNTEL0BaseN frame, and their addresses in that frame are RAZ/WI.

If an implementation supports 64-bit atomic accesses, then CNTPCT, CNTVCT, CNTVOFF, CNTP_CVAL, and CNTV_CVAL must be accessible as atomic 64-bit values.

CNTCTLBase status and control fields for the CNTBaseN and CNTEL0BaseN frames

In the CNTCTLBase frame:

CNTTIDR controls:

- Whether each CNTBaseN frame is implemented.
- If a CNTBaseN frame is implemented, whether:
 - That CNTBaseN frame has virtual timer capability.
 - A corresponding CNTEL0BaseN frame is implemented.

CNTNSAR controls:

In an implementation that recognizes two Security states, determines whether each implemented CNTBaseN frame, and any corresponding CNTEL0BaseN frame, is accessible by Non-secure accesses.

This control also determines whether, in the CNTCTLBase frame, the CNTACR<n> and CNTVOFF<n> registers are accessible by Non-secure accesses.

The CNTACR<n> registers control:

For each implemented CNTBaseN frame, the accessibility of the following registers in that frame:

- CNTP_CTL, CNTP_CVAL, and CNTP_TVAL.
- CNTV_CTL, CNTV_CVAL, and CNTV_TVAL.
- CNTVOFF.
- CNTFRQ.
- CNTPCT.
- CNTVCT.

For CNTACR<n>, the value of <n> corresponds to the value of N for the controlled CNTBaseN frame.

The CNTVOFF<n> registers provide:

For each implemented CNTBaseN frame that has virtual capability, the RW copy of the CNTVOFF register for that frame.

————— Note —————

In a CNTBaseN frame that has virtual timer capability the CNTVOFF register is RO.

For CNTVOFF<n>, the value of <n> corresponds to the value of N for the controlled CNTBaseN frame.

11.4 Providing a complete set of counter and timer features

Using the general model for implementing a memory-mapped interface to the Generic Timer described in this section, the feature set of a System registers counter and timer, in an implementation that includes EL2 and EL3, can be implemented using the following set of timer frames:

- A **CNTCTLBase** control frame.
- The following **CNTBaseN** timer frames:
 - Frame 0** Accessible from Non-secure state, with second view and virtual capability. This provides the Non-secure EL1&0 timers.
 - Frame 1** Accessible from Non-secure state, with no second view and no virtual capability. This provides the Non-secure EL2 timers.
 - Frame 2** Accessible only from Secure state, with a second view but no virtual capability. This provides the Secure PL1&0 timers, meaning:
 - Compared to a PE where EL3 is using AArch32, it provides the only Secure state timer.
 - Compared to a PE where EL3 is using AArch64, it provides the Secure EL1&0 timer.
 - Frame 3** Accessible only Secure state, with no second view and no virtual capability. This provides the Secure EL3 timers.

———— **Note** —————

This frame is not required for a memory-mapped timer that provides only the feature set of a PE for which EL3 is using AArch32.

In this implementation, the full set of implemented frames, and their configuration in the memory map, is as follows:

CNTCTLBase

The control frame. This frame is located in both Secure and Non-secure physical memory, and:

- In the Secure EL1&0 translation regime, this frame is accessible only at EL1.
- In the Non-secure EL2 translation regime, this frame is accessible.
- In the Non-secure EL1&0 translation regime, this frame is not accessible.

CNTBase0 The first view of the Non-secure EL1&0 timers. This frame is located only in Non-secure physical memory, and:

- In the Secure EL1&0 translation regime, this frame is accessible only at EL1.
- In the Non-secure EL2 translation regime, this frame is accessible.
- In the Non-secure EL1&0 translation regime, this frame is accessible only at EL1.

CNTEL0Base0

The second view of **CNTBase0**, meaning it is the EL0 view of the Non-secure EL1&0 timers. This frame is located only in Non-secure physical memory, and:

- In the Secure EL1&0 translation regime, the architecture permits this frame to be accessible at EL1, or at EL1 and EL0, but does not require either of these options.
- In the Non-secure EL2 translation regime, this frame is accessible.
- In the Non-secure EL1&0 translation regime, this frame is accessible at EL1 and EL0.

CNTBase1 The first and only view of the Non-secure EL2 timers. This frame is located only in Non-secure physical memory, and:

- When EL3 is using AArch64:
 - In the Secure EL1&0 translation regime, this frame is accessible only at EL1.
 - In the Secure EL3 translation regime, this frame is accessible.
- When EL3 is using AArch32, in the Secure PL1&0 translation regime, this frame is accessible only at PL1 (EL3).
- In the Non-secure EL2 translation regime, this frame is accessible.
- In the Non-secure EL1&0 translation regime, this frame is not accessible.

CNTBase2 The first view of the Secure EL1&0, or PL1&0 timers.

———— **Note** —————

In AArch64 state, these timers are always called the Secure EL1&0 timers. In AArch32 state they are usually called the Secure PL1&0 timers because, in AArch32 Secure state, whether some of the PE modes map to EL1 or to EL3 depends on whether EL3 is using AArch64 or is using AArch32, see [Security state, Exception levels, and AArch32 execution privilege](#) on page G1-4318.

—————

This frame is located only in Secure physical memory, and:

- When EL3 is using AArch64:
 - In the Secure EL1&0 translation regime, this frame is accessible only at EL1.
 - In the Secure EL3 translation regime, this frame is accessible.
- When EL3 is using AArch32, in the Secure PL1&0 translation regime, this frame is accessible only at PL1 (EL3).
- Because the frame is in Secure memory, it is not accessible in any Non-secure translation regime.

CNTEL0Base2

The second view of **CNTBase2**, meaning it is the EL0 view of the Secure EL1&0, or PL1&0, timers.

———— **Note** —————

See the Note in the description of the CNTBase2 frame for more information about the naming of these timers.

—————

This frame is located only in Secure physical memory, and:

- When EL3 is using AArch64:
 - In the Secure EL1&0 translation regime, this frame is accessible at EL1 and EL0.
 - In the Secure EL3 translation regime, this frame is accessible.
- When EL3 is using AArch32, in the Secure PL1&0 translation regime, this frame is accessible at PL1 (EL3) and EL0.
- Because the frame is in Secure memory, it is not accessible in any Non-secure translation regime.

CNTBase3 The first and only view of the EL3 timers. This frame is located only in Secure physical memory, and:

- When EL3 is using AArch64:
 - In the Secure EL1&0 translation regime, this frame is not accessible.
 - In the Secure EL3 translation regime, this frame is accessible.
- When EL3 is using AArch32, this frame is not accessible.
- Because the frame is in Secure memory, it is not accessible in any Non-secure translation regime.

———— **Note** —————

[About the Virtual Memory System Architecture \(VMSA\)](#) on page D4-2004 describes the VMSAv8-64 translation regimes, and [About VMSAv8-32](#) on page G4-4558 describes the VMSAv8-32 translation regimes.

I1.5 Gray-count scheme for timer distribution scheme

The distribution of the Counter value using a Gray-code provides a relatively simple mechanism to avoid any danger of the count being sampled with an intermediate value even if the clocking is asynchronous. It has a further advantage that the distribution is relatively low power, since only one bit changes on the main distribution wires for each clock tick.

A suitable Gray-coding scheme can be achieved with the following logic:

$$\text{Gray}[N] = \text{Count}[N]$$

$$\text{Gray}[i] = (\text{XOR}(\text{Gray}[N:i+1])) \text{ XOR } \text{Count}[i] \text{ for } N-1 \geq i \geq 0$$

$$\text{Count}[i] = \text{XOR}(\text{Gray}[N:i]) \text{ for } N \geq i \geq 0$$

This is for an $N+1$ bit counter, where Count is a conventional binary count value, and Gray is the corresponding Gray count value.

———— **Note** —————

This scheme has the advantage of being relatively simple to switch, in either direction, between operating with low-frequency and low-precision, and operating with high-frequency and high-precision. To achieve this, the ratio of the frequencies must be 2^n , where n is an integer. A switch-over can occur only on the $2n+1$ boundary to avoid losing the Gray-coding property on a switch-over.

Chapter I2

Recommended External Interface to the Performance Monitors

This chapter describes the recommended external interface to the Performance Monitors. It contains the following section:

- [About the external interface to the Performance Monitors registers on page I2-5738.](#)

———— **Note** —————

[Performance Monitors external register descriptions on page I3-5749](#) describes the external view of the Performance Monitors registers.

I2.1 About the external interface to the Performance Monitors registers

ARM recommends that:

- An implementation provides the OPTIONAL external debug interface to the Performance Monitors registers.

———— **Note** —————

A debugger can use this interface to access counters in the Performance Monitors.

- The implementation includes the OPTIONAL support for memory-mapped access to the External debug interface.

———— **Note** —————

— Software running on any PE in a system can use this interface to access counters in the Performance Monitors.

— Privileged software should use the MMU to control access to this interface.

- The external debug interface is implemented as defined in [Appendix K2 Recommended External Debug Interface](#).

When an implementation supports memory-mapped access to the external debug interface the interface is accessed as a little-endian memory-mapped peripheral. [External Performance Monitors registers summary on page I3-5746](#) gives the memory map of these registers.

The following sections describe the memory-mapped views of the Performance Monitors registers:

- [Differences in the external views of the Performance Monitors registers](#).
- [Synchronization of changes to the memory-mapped views on page I2-5739](#).
- [Access permissions for external views of the Performance Monitors on page I2-5739](#).

In this section, unless the context explicitly indicates otherwise, any reference to *a memory-mapped view* applies equally to a register view using:

- A access through an external debug interface.
- A memory-mapped access.

I2.1.1 Differences in the external views of the Performance Monitors registers

An external view of the Performance Monitors registers accesses the same registers as the System registers interface described in [Performance Monitors Extension registers on page D5-2176](#), except that:

1. The [PMSELR](#) is accessible only in the System registers interface.
2. The following registers are accessible only in external views:
 - [PMCFGR](#)
 - [PMDEVAFF0](#)
 - [PMDEVAFF1](#)
 - [PMLAR](#)
 - [PMLSR](#)
 - [PMAUTHSTATUS](#)
 - [PMDEVARCH](#)
 - [PMDEVTYPE](#)
 - [PMPIDR0](#)
 - [PMPIDR1](#)
 - [PMPIDR2](#)
 - [PMPIDR3](#)

- [PMPIDR4](#)
- [PMCIDR0](#)
- [PMCIDR1](#)
- [PMCIDR2](#)
- [PMCIDR3](#)

[Performance Monitors external register descriptions on page I3-5749](#) describes these registers.

3. The following controls do not affect the external views:
 - [PMSELR](#).
 - [PMUSERENR](#).
 - [HDCR](#). {TPM, TPMCR, HPMN}.

Instead, see the register descriptions in [Chapter I3 External System Control Register Descriptions](#).

I2.1.2 Synchronization of changes to the memory-mapped views

If a Performance Monitor is visible in both System register and an external view, and is accessed simultaneously through these two mechanisms, the behavior must be as if the access occurred atomically in any order. For more information, see [Synchronization of changes to the external debug registers on page H8-5554](#).

I2.1.3 Access permissions for external views of the Performance Monitors

For more information, see [External debug interface register access permissions on page H8-5561](#).

[Table I2-1 on page I2-5740](#) shows the access permissions for the Performance Monitors registers in a v8 Debug implementation. This table uses the following terms:

DLK	When the OS Double Lock is locked, DoubleLockStatus() == TRUE, accesses to some registers produce an error. Applies to both interfaces.
EPMAD	When AllowExternalPMUAccess() == FALSE, external debug access is disabled. See also Behavior of a not permitted memory-mapped access on page H8-5559 .
Error	Indicates that the access gives an error response.
Default	This shows the default access permissions, if none of the conditions in this list prevent access to the register.
Off	When EDPRSR.PU == 0, the Core power domain is completely off, or in a low-power state where the Core power domain registers cannot be accessed.

———— **Note** —————

If debug power is off, then all external debug interface accesses return an error.

OSLK	When the OS Lock is locked, OSLAR_EL1.OSLK == 1, accesses to some registers produces an error. This column shows the effect of this control on accesses using the external debug interface.
SLK	This indicates the modified default access permissions for OPTIONAL memory-mapped accesses to the external debug interface if the OPTIONAL Software Lock is locked. See Register access permissions for memory-mapped accesses on page H8-5558 . For all other accesses, this column is ignored.
-	Indicates that the control has no effect on the behavior of the access: <ul style="list-style-type: none">• If no other control affects the behavior, the Default access behavior applies.

- However, another control might determine the behavior.

Table I2-1 Access permissions for the Performance Monitors registers

Offset	Register	Domain	Off	DLK	OSLK	EPMA	Default	SLK
0x000+8xn	PMEVCNTR<n>_EL0 ^a	Core	Error	Error	Error	Error	RW	RO

0xE24	PMCEID1	Core	Error	Error	Error	Error	RO	RO
0xE80-0xEFC	Integration registers	-	Access is IMPLEMENTATION DEFINED					
0xF00-0xFFC	<i>Management registers and CoreSight compliance on page K2-6141</i>							

a. Implemented counters only. *n* is the counter number.

- b. Implemented only if the [OPTIONAL PC Sample-based Profiling Extension](#) is implemented and [ARMv8.2-PCSample](#) is implemented. See [Chapter H7 The PC Sample-based Profiling Extension](#).
- c. Only if the [OPTIONAL PMSWINC_EL0](#) register is implemented in the external debug interface.

I2.1.4 Power domains and Performance Monitors registers reset

For ARMv8-A implementations, ARM recommends that Performance Monitors are implemented as part of the core power domain, not as part of a separate debug power domain. There is no interface to access the Performance Monitors registers when the core power domain is powered down.

A Warm or Cold reset sets the Performance Monitors registers to their reset values. An External Debug reset does not change the values of the Performance Monitors registers.

For more information about the reset scheme recommended for a v8 Debug implementation see [Chapter H6 Debug Reset and Powerdown Support](#).

[Table I2-2](#) shows the Performance Monitors register resets for writable register fields. The column headings use the following terms:

- 64** This is the architectural reset value when resetting into AArch64 state.
- 32** This is the architectural reset value when resetting into AArch32 state.
- This indicates an IMPLEMENTATION DEFINED reset value on the specified reset. This might be UNKNOWN.

———— **Note** —————

This table does not include:

- Read-only identification registers and fields that have a fixed value. In this case, the reset value is that fixed value. An example of this is [PMCR_EL0.N](#).
- Write-only registers and fields that only have an effect on writes. These do not have a reset value. An example of this is [PMSWINC_EL0](#).
- IMPLEMENTATION DEFINED registers. In this case, the reset domains are IMPLEMENTATION DEFINED. The reset values are IMPLEMENTATION DEFINED and might be UNKNOWN.

Table I2-2 Performance Monitors System register resets

Register	Domain	Field	64	32	Description
PMCR_EL0	Warm	DP	-	0	Disable PMCCNTR_EL0 when prohibited
		X	-	0	Export enable
		D	-	0	Clock divider
		E	0	0	Performance Monitors enable
PMCNTENSET_EL0 PMCNTENCLR_EL0	Warm	-	-	-	All fields in register
PMOVSSET_EL0 PMOVSCLR_EL0	Warm	-	-	-	All fields in register

Chapter I3

External System Control Register Descriptions

This chapter describes the external system control registers and supported access sizes. It excludes the External debug registers that are described in [Chapter H9 External Debug Register Descriptions](#). It contains the following sections:

- [About the external system control register descriptions on page I3-5744.](#)
- [Supported access sizes on page I3-5745.](#)
- [External Performance Monitors registers summary on page I3-5746.](#)
- [Performance Monitors external register descriptions on page I3-5749.](#)
- [Generic Timer memory-mapped registers overview on page I3-5815.](#)
- [Generic Timer memory-mapped register descriptions on page I3-5816.](#)

13.1 About the external system control register descriptions

This chapter describes the external system control registers other than the external debug registers. That is, it describes:

An external view of the Performance Monitors registers

ARM recommends that implementations provide access to the Performance Monitors registers through the OPTIONAL External debug interface, and provide the OPTIONAL memory-mapped interface to this interface:

- [External Performance Monitors registers summary on page I3-5746](#) lists the registers that are accessible in this view of the Performance Monitors, and describes their memory map.
- [Performance Monitors external register descriptions on page I3-5749](#) describes each of the memory-mapped registers.

[Chapter I2 Recommended External Interface to the Performance Monitors](#) describes the recommended interface to these registers.

Note

[Chapter D5 The Performance Monitors Extension](#) describes the Performance Monitors. The following sections describe the System register interfaces to the Performance Monitors:

- [Performance Monitors registers on page D7-2629](#), for accesses from an Exception level that is using AArch64.
 - [Performance Monitors registers on page G6-5331](#), for accesses from an Exception level that is using AArch32.
-

The registers for the system level Generic Timer component

Any implementation that includes the Generic Timer must include the memory-mapped system level component described in [Chapter I1 System Level Implementation of the Generic Timer](#). In this chapter:

- [Generic Timer memory-mapped registers overview on page I3-5815](#) gives an overview of the registers, referring to [Chapter I1](#) for more information.
- [Generic Timer memory-mapped register descriptions on page I3-5816](#) describes each of the memory-mapped registers.

Note

[Chapter D6 The Generic Timer in AArch64 state](#) describes the Generic Timer component that is accessible using the System registers. The following sections describe the System register interfaces to that component:

- [Generic Timer registers on page D7-2672](#), for accesses from an Exception level that is using AArch64.
 - [Generic Timer registers on page G6-5383](#), for accesses from an Exception level that is using AArch32.
-

Note

[Chapter H9 External Debug Register Descriptions](#) describes the external debug registers.

I3.2 Supported access sizes

All of the information that is provided in this section applies to all accesses to memory-mapped components of the ARMv8 architecture, unless a register or component description explicitly states otherwise.

The memory access sizes that are supported by any peripheral are IMPLEMENTATION DEFINED by the peripheral.

For accesses to memory-mapped components of the ARMv8 architecture, implementations must support the following options:

- Word-aligned 32-bit accesses to access 32-bit registers.
- Word-aligned 32-bit accesses to either half of a 64-bit register that is mapped to a doubleword-aligned pair of adjacent 32-bit locations,
- Doubleword-aligned 64-bit accesses to access 64-bit registers that are mapped to a doubleword-aligned pair of adjacent 32-bit locations.

All registers are only single-copy atomic at word granularity. This means that for 64-bit accesses to a 64-bit register, the system might generate a pair of 32-bit accesses. The order in which the two halves are accessed is not specified.

The following accesses are not supported:

- Byte accesses.
- Halfword accesses.
- Unaligned word accesses. These accesses are not word single-copy atomic.
- Unaligned doubleword accesses. These accesses are not doubleword single-copy atomic.
- Doubleword accesses to a pair of 32-bit locations that are not a doubleword-aligned pair that forms a 64-bit register.
- Quadword accesses or higher accesses.
- Exclusive accesses.

For unsupported accesses, it is CONSTRAINED UNPREDICTABLE whether:

- The access generates an external abort or not.
- The defined side-effects of a read occur or not. A read returns UNKNOWN values.
- A write is ignored or sets the accessed register or registers to UNKNOWN.

For memory-mapped accesses from a PE that complies with an ARM architecture, the single-copy atomicity rules for the instruction, the type of instruction, and the type of memory that is accessed, determine the size of the access that is made by an instruction. [Example I3-1](#) shows this.

Example I3-1 Access sizes for memory-mapped accesses

Two Load Doubleword instructions that are made to consecutive doubleword-aligned locations generate a pair of single-copy atomic doubleword reads. However, if the accesses are made to Normal memory or Device-GRE memory they might appear as a single quadword access that is not supported by the peripheral.

The ARMv8 architecture does not require the size of each element that is accessed by a multi-register load or store instruction to be identifiable by the memory system beyond the PE. Unless otherwise specified by the component, any access to a memory-mapped component of the ARMv8 architecture is defined to be beyond the PE.

Software must use a Device-nGRE or stronger memory type, and only single register load and store instructions, to create memory accesses that are supported by the peripheral. For more information, see [Memory types and attributes on page B2-107](#).

I3.3 External Performance Monitors registers summary

When an implementation provides access to the Performance Monitors registers through the External debug interface, that interface provides access to:

- Performance Monitors System registers.
- A read-only configuration register, [PMCFGR](#).
- The OPTIONAL CoreSight registers for the Performance Monitors, if they are implemented.

The locations of the registers are defined as offsets from a system-defined base address. [Performance Monitors external register views](#) defines this memory map.

I3.3.1 Performance Monitors external register views

[Table I3-1](#) shows the external view of the Performance Monitors registers. All other entries are reserved.

———— **Note** —————

- Counters that are reserved because [HDCR.HPMN](#) has been changed from its reset value remain visible in any external view.
- The registers that relate to an implemented event counter, PMN_x, are [PMEVCNTR<n>](#) and [PMEVTYPER<n>](#).
- The mapping of the *Performance Monitors Event Counter Registers*, at offsets 0x000-0x0F4, has changed compared to the mappings of the equivalent registers in ARMv7.

Each entry in the Name column links to the register description in [Performance Monitors external register descriptions](#) on page I3-5749, and:

- If the *System register?* column of the table shows that the register is a System register, the memory-mapped interface provides a view of the System register described in:
 - [Performance Monitors registers](#) on page D7-2629, for the AArch64 System register
 - [Performance Monitors registers](#) on page G6-5331, for the AArch32 System register
- Otherwise, the register is accessible only using the external interface.

Table I3-1 Performance Monitors external register views

Name	Type	Description	System register?	Offset
PMEVCNTR<n>_EL0	RW	Performance Monitors Event Counter Register.	Yes	0x000+8n
PMCCNTR_EL0[31:0] PMCCNTR_EL0[63:32]	RW	Performance Monitors Cycle Counter Register ^a	Yes	0x0F8 0x0FC
PMPCSR[31:0]^b	RW	Program Counter Sample Register, bits[31:0]	No	0x200

PMLSR ^{c, d}	RO	Lock Status register	No	0xFB4
PMAUTHSTATUS ^c	RO	Authentication Status register	No	0xFB8
PMDEVARCH ^c	RO	Device Architecture register	No	0xFBC
PMDEVID	RO	Performance Monitors Device ID register	No	0xFC8
PMDEVTYPE ^c	RO	Device Type register	No	0xFCC
PMPIDR4 ^c	RO	Peripheral ID registers	No	0xFD0
PMPIDR0 ^c	RO			0xFE0
PMPIDR1 ^c	RO			0xFE4
PMPIDR2 ^c	RO			0xFE8
PMPIDR3 ^c	RO			0xFEC

Table I3-1 Performance Monitors external register views (continued)

Name	Type	Description	System register?	Offset
PMCIDR0^c	RO	Component ID registers	No	0xFF0
PMCIDR1^c	RO			0xFF4
PMCIDR2^c	RO			0xFF8
PMCIDR3^c	RO			0xFFC

- a. The interface must support at least single-copy atomic 32-bit accesses. If single-copy atomic 64-bit access to the registers is not possible, software must use a high-low-high read access to read the counter value if the counter is enabled.
- b. Supported from ARMv8.2. Until ARMv8.1, the functionality of PC Sample-Based Profiling is implemented with registers in the EDxxx space. See Chapter H7 *The PC Sample-based Profiling Extension*.
 Implemented only if the OPTIONAL PC Sample-based Profiling Extension is implemented.
- c. CoreSight interface registers, see [Management registers and CoreSight compliance on page K2-6141](#).
- d. The Software lock registers are defined as part of CoreSight compliance, but their contents depend on the type of access that is made and whether the OPTIONAL Software lock is implemented. See the register description for details.

I3.4 Performance Monitors external register descriptions

This section describes the external view of the Performance Monitors registers. [External Performance Monitors registers summary on page I3-5746](#) lists these registers in offset order.

13.4.1 PMAUTHSTATUS, Performance Monitors Authentication Status register

The PMAUTHSTATUS characteristics are:

Purpose

Provides information about the state of the IMPLEMENTATION DEFINED authentication interface for Performance Monitors.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

PMAUTHSTATUS is in the Debug power domain.

This register is OPTIONAL, and is required for CoreSight compliance. ARM recommends that this register is implemented.

Attributes

PMAUTHSTATUS is a 32-bit register.

Field descriptions

The PMAUTHSTATUS bit assignments are:

Bits [31:8]

Reserved, RES0.

SNID, bits [7:6]

Holds the same value as [DBGAUTHSTATUS_EL1.SNID](#).

SID, bits [5:4]

Secure invasive debug. Possible values of this field are:

00 Not implemented.

All other values are reserved.

NSNID, bits [3:2]

Holds the same value as [DBGAUTHSTATUS_EL1.NSNID](#).

NSID, bits [1:0]

Non-secure invasive debug. Possible values of this field are:

00 Not implemented.

All other values are reserved.

Accessing the PMAUTHSTATUS:

PMAUTHSTATUS can be accessed through the external debug interface:

Component	Offset
PMU	0xFB8

13.4.2 PMCCFILTR_EL0, Performance Monitors Cycle Counter Filter Register

The PMCCFILTR_EL0 characteristics are:

Purpose

Determines the modes in which the Cycle Counter, [PMCCNTR_EL0](#), increments.

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	EPMAD	SLK	Default
Error	Error	Error	Error	RO	RW

Configurations

External register PMCCFILTR_EL0 is architecturally mapped to AArch64 System register [PMCCFILTR_EL0](#).

External register PMCCFILTR_EL0 is architecturally mapped to AArch32 System register [PMCCFILTR](#).

PMCCFILTR_EL0 is in the Core power domain.

On a Warm or Cold reset RW fields in this register reset:

- To architecturally UNKNOWN values if the reset is to an Exception level that is using AArch64.
- To 0 if the reset is to an Exception level that is using AArch32.

The register is not affected by an External debug reset.

Attributes

PMCCFILTR_EL0 is a 32-bit register.

Field descriptions

The PMCCFILTR_EL0 bit assignments are:

P, bit [31]

Privileged filtering bit. Controls counting in EL1. If EL3 is implemented, then counting in Non-secure EL1 is further controlled by the NSK bit. The possible values of this bit are:

- 0 Count cycles in EL1.
- 1 Do not count cycles in EL1.

U, bit [30]

User filtering bit. Controls counting in EL0. If EL3 is implemented, then counting in Non-secure EL0 is further controlled by the NSU bit. The possible values of this bit are:

- 0 Count cycles in EL0.

1 Do not count cycles in EL0.

NSK, bit [29]

Non-secure EL1 (kernel) modes filtering bit. Controls counting in Non-secure EL1. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of P, cycles in Non-secure EL1 are counted.

Otherwise, cycles in Non-secure EL1 are not counted.

NSU, bit [28]

Non-secure EL0 (Unprivileged) filtering. Controls counting in Non-secure EL0. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of U, cycles in Non-secure EL0 are counted.

Otherwise, cycles in Non-secure EL0 are not counted.

NSH, bit [27]

Non-secure EL2 (Hypervisor) filtering bit. Controls counting in Non-secure EL2. If EL2 is not implemented, this bit is RES0.

0 Do not count cycles in EL2.

1 Count cycles in EL2.

M, bit [26]

Secure EL3 filtering bit. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of P, cycles in Secure EL3 are counted.

Otherwise, cycles in Secure EL3 are not counted.

Most applications can ignore this field and set its value to 0.

———— **Note** —————

This field is not visible in the AArch32 PMCCFILTR System register.

Bits [25:0]

Reserved, RES0.

Accessing the PMCCFILTR_EL0:

PMCCFILTR_EL0 can be accessed through the external debug interface:

Component	Offset
PMU	0x47C

13.4.3 PMCCNTR_EL0, Performance Monitors Cycle Counter

The PMCCNTR_EL0 characteristics are:

Purpose

Holds the value of the processor Cycle Counter, CCNT, that counts processor clock cycles. See [Time as measured by the Performance Monitors cycle counter on page D5-2139](#) for more information.

[PMCCFILTR_EL0](#) determines the modes and states in which the PMCCNTR_EL0 can increment.

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	EPMAD	SLK	Default
Error	Error	Error	Error	RO	RW

Configurations

External register PMCCNTR_EL0 is architecturally mapped to AArch64 System register [PMCCNTR_EL0](#).

External register PMCCNTR_EL0 is architecturally mapped to AArch32 System register [PMCCNTR](#).

PMCCNTR_EL0 is in the Core power domain. RW fields in this register reset to architecturally UNKNOWN values. These apply on a Warm or Cold reset. The register is not affected by an External debug reset.

Attributes

PMCCNTR_EL0 is a 64-bit register.

Field descriptions

The PMCCNTR_EL0 bit assignments are:

CCNT, bits [63:0]

Cycle count. Depending on the values of [PMCR_EL0](#).{LC, D}, the cycle count increments in one of the following ways:

- Every processor clock cycle.
- Every 64th processor clock cycle.

Writing 1 to [PMCR_EL0](#).C sets this field to 0.

This field resets to a value that is architecturally UNKNOWN.

Accessing the PMCCNTR_EL0:

PMCCNTR_EL0[31:0] can be accessed through the external debug interface:

Component	Offset
PMU	0x0F8

PMCCNTR_EL0[63:32] can be accessed through the external debug interface:

Component	Offset
PMU	0x0FC

I3.4.4 PMCEID0, Performance Monitors Common Event Identification register 0

The PMCEID0 characteristics are:

Purpose

Defines which common architectural and common microarchitectural feature events in the range 0x000 to 0x01F are implemented. If a particular bit is set to 1, then the event for that bit is implemented.

———— **Note** —————

This view of the register has previously been called PMCEID0_EL0.

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	EPMAD	SLK	Default
Error	Error	Error	Error	RO	RO

Configurations

External register PMCEID0 is architecturally mapped to AArch64 System register [PMCEID0_EL0](#)[31:0].

External register PMCEID0[31:0] is architecturally mapped to AArch32 System register [PMCEID0](#).

PMCEID0 is in the Core power domain.

Attributes

PMCEID0 is a 32-bit register.

Field descriptions

The PMCEID0 bit assignments are:

ID[31:0], bits [31:0]

PMCEID0[n] maps to event n. For a list of event numbers and descriptions, see [Events, event numbers, and mnemonics on page D5-2152](#).

For each bit:

- 0 The common event is not implemented.
- 1 The common event is implemented.

Bits that map to reserved event numbers are reserved to identify events that might be defined in future revisions to the architecture.

Events that do not require additional features in the PMU can be defined retrospectively, meaning that they can be implemented as part of a PMUv3 implementation.

Accessing the PMCEID0:

PMCEID0 can be accessed through the external debug interface:

Component	Offset
PMU	0xE20

I3.4.5 PMCEID1, Performance Monitors Common Event Identification register 1

The PMCEID1 characteristics are:

Purpose

Defines which common architectural and common microarchitectural feature events in the range 0x020 to 0x03F are implemented. If a particular bit is set to 1, then the event for that bit is implemented.

———— **Note** —————

This view of the register has previously been called PMCEID1_EL0.

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	EPMAD	SLK	Default
Error	Error	Error	Error	RO	RO

Configurations

External register PMCEID1 is architecturally mapped to AArch64 System register [PMCEID1_EL0](#)[31:0].

External register PMCEID1[31:0] is architecturally mapped to AArch32 System register [PMCEID1](#).

PMCEID1 is in the Core power domain.

Attributes

PMCEID1 is a 32-bit register.

Field descriptions

The PMCEID1 bit assignments are:

ID[63:32], bits [31:0]

PMCEID1[n] maps to event (n + 32). For a list of event numbers and descriptions, see [Events, event numbers, and mnemonics on page D5-2152](#).

For each bit:

0 The common event is not implemented.

1 The common event is implemented.

Bits that map to reserved event numbers are reserved to identify events that might be defined in future revisions to the architecture.

Events that do not require additional features in the PMU can be defined retrospectively, meaning that they can be implemented as part of a PMUv3 implementation.

Accessing the PMCEID1:

PMCEID1 can be accessed through the external debug interface:

Component	Offset
PMU	0xE24

13.4.6 PMCEID2, Performance Monitors Common Event Identification register 2

The PMCEID2 characteristics are:

Purpose

Defines which common architectural and common microarchitectural feature events in the range 0x4000 to 0x401F are implemented. If a particular bit is set to 1, then the event for that bit is implemented.

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	EPMA	SLK	Default
Error	Error	Error	Error	RO	RO

Configurations

External register PMCEID2 is architecturally mapped to AArch64 System register [PMCEID0_EL0](#)[63:32].

External register PMCEID2[63:32] is architecturally mapped to AArch32 System register [PMCEID2](#).

PMCEID2 is in the Core power domain.

This register is introduced in ARMv8.1.

Attributes

PMCEID2 is a 32-bit register.

Field descriptions

The PMCEID2 bit assignments are:

ID[16415:16384], bits [31:0]

PMCEID2[31:0] maps to common events 0x4000 to 0x401F. For a list of event numbers and descriptions, see [Events, event numbers, and mnemonics on page D5-2152](#).

For each bit:

0 The common event is not implemented.

1 The common event is implemented.

Bits that map to reserved event numbers are reserved to identify events that might be defined in future revisions to the architecture.

Events that do not require additional features in the PMU can be defined retrospectively, meaning that they can be implemented as part of a PMUv3 implementation.

Accessing the PMCEID2:

PMCEID2 can be accessed through the external debug interface:

Component	Offset
PMU	0xE28

13.4.7 PMCEID3, Performance Monitors Common Event Identification register 3

The PMCEID3 characteristics are:

Purpose

Defines which common architectural and common microarchitectural feature events in the range 0x4020 to 0x403F are implemented. If a particular bit is set to 1, then the event for that bit is implemented.

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	EPMA	SLK	Default
Error	Error	Error	Error	RO	RO

Configurations

External register PMCEID3 is architecturally mapped to AArch64 System register [PMCEID1_ELO](#)[63:32].

External register PMCEID3[63:32] is architecturally mapped to AArch32 System register [PMCEID3](#).

PMCEID3 is in the Core power domain.

This register is introduced in ARMv8.1.

Attributes

PMCEID3 is a 32-bit register.

Field descriptions

The PMCEID3 bit assignments are:

ID[16447:16416], bits [31:0]

PMCEID3[31:0] maps to common events 0x4020 to 0x403F. For a list of event numbers and descriptions, see [Events, event numbers, and mnemonics on page D5-2152](#).

For each bit:

0 The common event is not implemented.

1 The common event is implemented.

Bits that map to reserved event numbers are reserved to identify events that might be defined in future revisions to the architecture.

Events that do not require additional features in the PMU can be defined retrospectively, meaning that they can be implemented as part of a PMUv3 implementation.

Accessing the PMCEID3:

PMCEID3 can be accessed through the external debug interface:

Component	Offset
PMU	0xE2C

13.4.8 PMCFGR, Performance Monitors Configuration Register

The PMCFGR characteristics are:

Purpose

Contains PMU-specific configuration data.

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	EPMAD	SLK	Default
Error	Error	Error	Error	RO	RO

Configurations

PMCFGR is in the Core power domain.

Attributes

PMCFGR is a 32-bit register.

Field descriptions

The PMCFGR bit assignments are:

NCG, bits [31:28]

This feature is not supported, so this field is RAZ.

Bits [27:20]

Reserved, RES0.

UEN, bit [19]

User-mode Enable Register supported. [PMUSERENR_ELO](#) is not visible in the external debug interface, so this bit is RAZ.

WT, bit [18]

This feature is not supported, so this bit is RAZ.

NA, bit [17]

This feature is not supported, so this bit is RAZ.

EX, bit [16]

Export supported. Value is IMPLEMENTATION DEFINED.

0 [PMCR_ELO.X](#) is RES0.

1 [PMCR_ELO.X](#) is read/write.

CCD, bit [15]

Cycle counter has prescale. This is RES1 if AArch32 is supported at any EL, and RAZ otherwise.

0 [PMCR_ELO.D](#) is RES0.

1 [PMCR_ELO.D](#) is read/write.

CC, bit [14]

Dedicated cycle counter (counter 31) supported. This bit is RAO.

SIZE, bits [13:8]

Size of counters. This field determines the spacing of counters in the memory-map.

In ARMv8 the counters are at doubleword-aligned addresses, and the largest counter is 64-bits, so this field is 0b111111.

N, bits [7:0]

Number of counters implemented in addition to the cycle counter, [PMCCNTR_ELO](#). The maximum number of event counters is 31.

00000000 Only [PMCCNTR_ELO](#) implemented.

00000001 [PMCCNTR_ELO](#) plus one event counter implemented.

and so on up to 0b00011111, which indicates [PMCCNTR_ELO](#) and 31 event counters implemented.

Accessing the PMCFGR:

PMCFGR can be accessed through the external debug interface:

Component	Offset
PMU	0xE00

13.4.9 PMCIDR0, Performance Monitors Component Identification Register 0

The PMCIDR0 characteristics are:

Purpose

Provides information to identify a Performance Monitor component.

For more information see [About the Component Identification scheme on page K2-6149](#).

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

PMCIDR0 is in the Debug power domain.

Implementation of this register is OPTIONAL.

This register is required for CoreSight compliance.

Attributes

PMCIDR0 is a 32-bit register.

Field descriptions

The PMCIDR0 bit assignments are:

Bits [31:8]

Reserved, RES0.

PRMBL_0, bits [7:0]

Preamble. Must read as 0x00.

Accessing the PMCIDR0:

PMCIDR0 can be accessed through the external debug interface:

Component	Offset
PMU	0xFF0

13.4.10 PMCIDR1, Performance Monitors Component Identification Register 1

The PMCIDR1 characteristics are:

Purpose

Provides information to identify a Performance Monitor component.

For more information see [About the Component Identification scheme on page K2-6149](#).

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

PMCIDR1 is in the Debug power domain.

Implementation of this register is OPTIONAL.

This register is required for CoreSight compliance.

Attributes

PMCIDR1 is a 32-bit register.

Field descriptions

The PMCIDR1 bit assignments are:

Bits [31:8]

Reserved, RES0.

CLASS, bits [7:4]

Component class. Reads as 0x9, debug component.

PRMBL_1, bits [3:0]

Preamble. RAZ.

Accessing the PMCIDR1:

PMCIDR1 can be accessed through the external debug interface:

Component	Offset
PMU	0xFF4

13.4.11 PMCIDR2, Performance Monitors Component Identification Register 2

The PMCIDR2 characteristics are:

Purpose

Provides information to identify a Performance Monitor component.

For more information see [About the Component Identification scheme on page K2-6149](#).

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

PMCIDR2 is in the Debug power domain.

Implementation of this register is OPTIONAL.

This register is required for CoreSight compliance.

Attributes

PMCIDR2 is a 32-bit register.

Field descriptions

The PMCIDR2 bit assignments are:

Bits [31:8]

Reserved, RES0.

PRMBL_2, bits [7:0]

Preamble. Must read as 0x05.

Accessing the PMCIDR2:

PMCIDR2 can be accessed through the external debug interface:

Component	Offset
PMU	0xFF8

13.4.12 PMCIDR3, Performance Monitors Component Identification Register 3

The PMCIDR3 characteristics are:

Purpose

Provides information to identify a Performance Monitor component.

For more information see [About the Component Identification scheme on page K2-6149](#).

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

PMCIDR3 is in the Debug power domain.

Implementation of this register is OPTIONAL.

This register is required for CoreSight compliance.

Attributes

PMCIDR3 is a 32-bit register.

Field descriptions

The PMCIDR3 bit assignments are:

Bits [31:8]

Reserved, RES0.

PRMBL_3, bits [7:0]

Preamble. Must read as 0xB1.

Accessing the PMCIDR3:

PMCIDR3 can be accessed through the external debug interface:

Component	Offset
PMU	0xFFC

I3.4.13 PMCID1SR, CONTEXTIDR_EL1 Sample Register

The PMCID1SR characteristics are:

Purpose

Contains the sampled value of [CONTEXTIDR_EL1](#), captured on reading [PMPCSR](#)[31:0].

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	SLK	Default
Error	Error	Error	RO	RO

Configurations

PMCID1SR is in the Core power domain.

Fields in this register reset to architecturally UNKNOWN values. These apply only on a Cold reset. The register is not affected by a Warm reset and is not affected by an External debug reset.

Implemented only if the OPTIONAL PC Sample-based Profiling Extension is implemented and [ARMv8.2-PCSample](#) is implemented. If the OPTIONAL PC Sample-based Profiling Extension is implemented and [ARMv8.2-PCSample](#) is not implemented, this register is not implemented and the architecture defines the functionality in [EDCIDS](#).

This register is introduced in ARMv8.2.

Attributes

PMCID1SR is a 32-bit register.

Field descriptions

The PMCID1SR bit assignments are:

CONTEXTIDR_EL1, bits [31:0]

Context ID. The value of [CONTEXTIDR](#) that is associated with the most recent [PMPCSR](#) sample.

- If EL1 is using AArch64, then the Context ID is held in [CONTEXTIDR_EL1](#).
- If EL1 is using AArch32, then the Context ID is held in [CONTEXTIDR](#).
- If EL3 is implemented and is using AArch32, then [CONTEXTIDR](#) is a banked register and PMCID1SR samples the current banked copy of [CONTEXTIDR](#) for the Security state that is associated with the most recent [PMPCSR](#) sample.

Because the value written to PMCID1SR is an indirect read of [CONTEXTIDR](#), therefore it is CONSTRAINED UNPREDICTABLE whether PMCID1SR is set to the original or new value if a read of [PMPCSR](#) samples:

- An instruction that writes to [CONTEXTIDR_EL1](#).
- The next Context synchronization event.
- Any instruction executed between these two instructions.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

Accessing the PMCID1SR:

PMCID1SR can be accessed through the external debug interface:

Component	Offset
PMU	0x208
PMU	0x228

I3.4.14 PMCID2SR, CONTEXTIDR_EL2 Sample Register

The PMCID2SR characteristics are:

Purpose

Contains the sampled value of [CONTEXTIDR_EL2](#), captured on reading [PMPCSR](#)[31:0].

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	SLK	Default
Error	Error	Error	RO	RO

Configurations

PMCID2SR is in the Core power domain.

Fields in this register reset to architecturally UNKNOWN values. These apply only on a Cold reset. The register is not affected by a Warm reset and is not affected by an External debug reset.

Implemented only if the OPTIONAL PC Sample-based Profiling Extension is implemented and [ARMv8.2-PCSample](#) is implemented. If the OPTIONAL PC Sample-based Profiling Extension is implemented and [ARMv8.2-PCSample](#) is not implemented, this register is not implemented and the architecture defines the functionality in [EDCDSR](#).

If EL2 is not implemented, this register is RES0.

This register is introduced in ARMv8.2.

Attributes

PMCID2SR is a 32-bit register.

Field descriptions

The PMCID2SR bit assignments are:

CONTEXTIDR_EL2, bits [31:0]

Context ID. The value of [CONTEXTIDR](#) that is associated with the most recent [PMPCSR](#) sample.

- If EL2 is using AArch64, then the Context ID is in [CONTEXTIDR_EL2](#).
- If EL2 is using AArch32, then this field is set to an UNKNOWN value.
- If [PMPCSR.NS](#)==0, this field is set to an UNKNOWN value.

Because the value written to PMCID2SR is an indirect read of [CONTEXTIDR](#), therefore it is CONSTRAINED UNPREDICTABLE whether PMCID2SR is set to the original or new value if a read of [PMPCSR](#) samples:

- An instruction that writes to [CONTEXTIDR_EL2](#).
- The next Context synchronization event.
- Any instruction executed between these two instructions.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

Accessing the PMCID2SR:

PMCID2SR can be accessed through the external debug interface:

Component	Offset
PMU	0x22C

13.4.15 PMCNTENCLR_EL0, Performance Monitors Count Enable Clear register

The PMCNTENCLR_EL0 characteristics are:

Purpose

Disables the Cycle Count Register, [PMCCNTR_EL0](#), and any implemented event counters [PMEVCNTR<n>](#). Reading this register shows which counters are enabled.

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	EPMA	SLK	Default
Error	Error	Error	Error	RO	RW

Configurations

External register PMCNTENCLR_EL0 is architecturally mapped to AArch64 System register [PMCNTENCLR_EL0](#).

External register PMCNTENCLR_EL0 is architecturally mapped to AArch32 System register [PMCNTENCLR](#).

PMCNTENCLR_EL0 is in the Core power domain. RW fields in this register reset to architecturally UNKNOWN values. These apply on a Warm or Cold reset. The register is not affected by an External debug reset.

Attributes

PMCNTENCLR_EL0 is a 32-bit register.

Field descriptions

The PMCNTENCLR_EL0 bit assignments are:

C, bit [31]

[PMCCNTR_EL0](#) disable bit. Disables the cycle counter register. Possible values are:

- 0 When read, means the cycle counter is disabled. When written, has no effect.
- 1 When read, means the cycle counter is enabled. When written, disables the cycle counter.

This field resets to a value that is architecturally UNKNOWN.

P<n>, bit [n], for n = 0 to 30

Event counter disable bit for [PMEVCNTR<n>_EL0](#).

Bits [30:N] are RAZ/WI. N is the value in [PMCFGR.N](#).

Possible values of each bit are:

- 0 When read, means that [PMEVCNTR<n>_EL0](#) is disabled. When written, has no effect.
- 1 When read, means that [PMEVCNTR<n>_EL0](#) is enabled. When written, disables [PMEVCNTR<n>_EL0](#).

This field resets to a value that is architecturally UNKNOWN.

Accessing the PMCNTENCLR_ELO:

PMCNTENCLR_ELO can be accessed through the external debug interface:

Component	Offset
PMU	0xC20

13.4.16 PMCNTENSET_EL0, Performance Monitors Count Enable Set register

The PMCNTENSET_EL0 characteristics are:

Purpose

Enables the Cycle Count Register, [PMCCNTR_EL0](#), and any implemented event counters [PMEVCNTR<n>](#). Reading this register shows which counters are enabled.

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	EPMA	SLK	Default
Error	Error	Error	Error	RO	RW

Configurations

External register PMCNTENSET_EL0 is architecturally mapped to AArch64 System register [PMCNTENSET_EL0](#).

External register PMCNTENSET_EL0 is architecturally mapped to AArch32 System register [PMCNTENSET](#).

PMCNTENSET_EL0 is in the Core power domain. RW fields in this register reset to architecturally UNKNOWN values. These apply on a Warm or Cold reset. The register is not affected by an External debug reset.

Attributes

PMCNTENSET_EL0 is a 32-bit register.

Field descriptions

The PMCNTENSET_EL0 bit assignments are:

C, bit [31]

[PMCCNTR_EL0](#) enable bit. Enables the cycle counter register. Possible values are:

- 0 When read, means the cycle counter is disabled. When written, has no effect.
- 1 When read, means the cycle counter is enabled. When written, enables the cycle counter.

This field resets to a value that is architecturally UNKNOWN.

P<n>, bit [n], for n = 0 to 30

Event counter enable bit for [PMEVCNTR<n>_EL0](#).

Bits [30:N] are RAZ/WI. N is the value in [PMCFGR.N](#).

Possible values of each bit are:

- 0 When read, means that [PMEVCNTR<n>_EL0](#) is disabled. When written, has no effect.
- 1 When read, means that [PMEVCNTR<n>_EL0](#) event counter is enabled. When written, enables [PMEVCNTR<n>_EL0](#).

This field resets to a value that is architecturally UNKNOWN.

Accessing the PMCNTENSET_ELO:

PMCNTENSET_ELO can be accessed through the external debug interface:

Component	Offset
PMU	0xC00

13.4.17 PMCR_EL0, Performance Monitors Control Register

The PMCR_EL0 characteristics are:

Purpose

Provides details of the Performance Monitors implementation, including the number of counters implemented, and configures and controls the counters.

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	EPMAD	SLK	Default
Error	Error	Error	Error	RO	RW

Configurations

External register PMCR_EL0[6:0] is architecturally mapped to AArch32 System register [PMCR](#)[6:0].

External register PMCR_EL0[6:0] is architecturally mapped to AArch64 System register [PMCR_EL0](#)[6:0].

PMCR_EL0 is in the Core power domain. Some or all RW fields of this register have defined reset values. These apply on a Warm or Cold reset. The register is not affected by an External debug reset.

This register is only partially mapped to the internal [PMCR](#) System register. An external agent must use other means to discover the information held in [PMCR](#)[31:11], such as accessing [PMCFGR](#) and the ID registers.

Attributes

PMCR_EL0 is a 32-bit register.

Field descriptions

The PMCR_EL0 bit assignments are:

Bits [31:11]

RAZ/WI. Hardware must implement this field as RAZ/WI. Software must not rely on the register reading as zero, and must use a read-modify-write sequence to write to the register.

Bits [10:7]

Reserved, RES0.

LC, bit [6]

Long cycle counter enable. Determines which [PMCCNTR_EL0](#) bit generates an overflow recorded by [PMOVSRR](#)[31].

0 Cycle counter overflow on increment that changes [PMCCNTR_EL0](#)[31] from 1 to 0.

1 Cycle counter overflow on increment that changes [PMCCNTR_EL0](#)[63] from 1 to 0.

ARM deprecates use of [PMCR_EL0](#).LC = 0.

In an AArch64-only implementation, this field is RES1.

If this field is implemented as an RW field, it resets to a value that is architecturally UNKNOWN.

DP, bit [5]

Disable cycle counter when event counting is prohibited. The possible values of this bit are:

- 0 `PMCCNTR_ELO`, if enabled, counts when event counting is prohibited.
- 1 `PMCCNTR_ELO` does not count when event counting is prohibited.

Counting events is never prohibited in Non-secure state. However, there are some restrictions on counting events in Secure state. For more information about the interaction between the Performance Monitors and EL3, see [Interaction with EL3 on page D5-2145](#).

When EL3 is not implemented, this field is RES0:

- When [ARMv8.1-PMU](#) is not implemented.
- When [ARMv8.1-PMU](#) is implemented, only if EL2 is not implemented.

Otherwise this field is RW.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field it resets to:

- A value that is architecturally UNKNOWN if the reset is into an Exception level that is using AArch64.
- 0 if the reset is into an Exception level that is using AArch32.

X, bit [4]

Enable export of events in an IMPLEMENTATION DEFINED event stream. The possible values of this bit are:

- 0 Do not export events.
- 1 Export events where not prohibited.

This field enables the exporting of events over an event bus to another device, for example to an OPTIONAL trace macrocell. If the implementation does not include such an event bus then this field is RAZ/WI, otherwise it is an RW field.

In an implementation that includes an event bus, no events are exported when counting is prohibited.

This field does not affect the generation of Performance Monitors overflow interrupt requests or signaling to a cross-trigger interface (CTI) that can be implemented as signals exported from the PE.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field it resets to:

- A value that is architecturally UNKNOWN if the reset is into an Exception level that is using AArch64.
- 0 if the reset is into an Exception level that is using AArch32.

D, bit [3]

Clock divider. The possible values of this bit are:

- 0 When enabled, `PMCCNTR_ELO` counts every clock cycle.
- 1 When enabled, `PMCCNTR_ELO` counts once every 64 clock cycles.

In an AArch64-only implementation this field is RES0, otherwise it is an RW field. If `PMCR_ELO.LC == 1`, this bit is ignored and the cycle counter counts every clock cycle.

ARM deprecates use of `PMCR_ELO.D = 1`.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field it resets to:

- A value that is architecturally UNKNOWN if the reset is into an Exception level that is using AArch64.
- 0 if the reset is into an Exception level that is using AArch32.

C, bit [2]

Cycle counter reset. This bit is WO. The effects of writing to this bit are:

- 0 No action.
- 1 Reset [PMCCNTR_EL0](#) to zero.

This bit is always RAZ.

Resetting [PMCCNTR_EL0](#) does not clear the [PMCCNTR_EL0](#) overflow bit to 0.

P, bit [1]

Event counter reset. This bit is WO. The effects of writing to this bit are:

- 0 No action.
- 1 Reset all event counters, not including [PMCCNTR_EL0](#), to zero.

This bit is always RAZ.

Resetting the event counters does not clear any overflow bits to 0.

E, bit [0]

Enable. The possible values of this bit are:

- 0 All counters, including [PMCCNTR_EL0](#), are disabled.
- 1 All counters are enabled by [PMCNTENSET_EL0](#).

This bit is RW.

When this register has an architecturally-defined reset value, this field resets to 0.

Accessing the PMCR_EL0:

PMCR_EL0 can be accessed through the external debug interface:

Component	Offset
PMU	0xE04

I3.4.18 PMDEVAFF0, Performance Monitors Device Affinity register 0

The PMDEVAFF0 characteristics are:

Purpose

Copy of the low half of the PE [MPIDR_EL1](#) register that allows a debugger to determine which PE in a multiprocessor system the Performance Monitor component relates to.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

PMDEVAFF0 is in the Debug power domain.

Implementation of this register is OPTIONAL.

Attributes

PMDEVAFF0 is a 32-bit register.

Field descriptions

The PMDEVAFF0 bit assignments are:

Bits [31:0]

[MPIDR_EL1](#) low half. Read-only copy of the low half of [MPIDR_EL1](#), as seen from the highest implemented Exception level.

Accessing the PMDEVAFF0:

PMDEVAFF0 can be accessed through the external debug interface:

Component	Offset
PMU	0xFA8

I3.4.19 PMDEVAFF1, Performance Monitors Device Affinity register 1

The PMDEVAFF1 characteristics are:

Purpose

Copy of the high half of the PE [MPIDR_EL1](#) register that allows a debugger to determine which PE in a multiprocessor system the Performance Monitor component relates to.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

PMDEVAFF1 is in the Debug power domain.

Implementation of this register is OPTIONAL.

Attributes

PMDEVAFF1 is a 32-bit register.

Field descriptions

The PMDEVAFF1 bit assignments are:

Bits [31:0]

[MPIDR_EL1](#) high half. Read-only copy of the high half of [MPIDR_EL1](#), as seen from the highest implemented Exception level.

Accessing the PMDEVAFF1:

PMDEVAFF1 can be accessed through the external debug interface:

Component	Offset
PMU	0xFAC

13.4.20 PMDEVARCH, Performance Monitors Device Architecture register

The PMDEVARCH characteristics are:

Purpose

Identifies the programmers' model architecture of the Performance Monitor component.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

PMDEVARCH is in the Debug power domain.

Attributes

PMDEVARCH is a 32-bit register.

Field descriptions

The PMDEVARCH bit assignments are:

ARCHITECT, bits [31:21]

Defines the architecture of the component. For Performance Monitors, this is ARM Limited.

Bits [31:28] are the JEP106 continuation code, 0x4.

Bits [27:21] are the JEP106 ID code, 0x3B.

PRESENT, bit [20]

When set to 1, indicates that the DEVARCH is present.

This field is 1 in ARMv8.

REVISION, bits [19:16]

Defines the architecture revision. For architectures defined by ARM this is the minor revision.

For Performance Monitors, the revision defined by ARMv8 is 0x0.

All other values are reserved.

ARCHID, bits [15:0]

Defines this part to be an ARMv8 debug component. For architectures defined by ARM this is further subdivided.

For Performance Monitors:

- Bits [15:12] are the architecture version, 0x2.
- Bits [11:0] are the architecture part number, 0xA16.

This corresponds to Performance Monitors architecture version PMUv3.

———— **Note** ————

The PMUv3 memory-mapped programmers' model can be used by devices other than ARMv8 processors. Software must determine whether the PMU is attached to an ARMv8 processor by using the [PMDEVAFF0](#) and [PMDEVAFF1](#) registers to discover the affinity of the PMU to any ARMv8 processors.

Accessing the PMDEVARCH:

PMDEVARCH can be accessed through the external debug interface:

Component	Offset
PMU	0xFBC

13.4.21 PMDEVID, Performance Monitors Device ID register

The PMDEVID characteristics are:

Purpose

Provides information about features of the debug implementation.

Usage constraints

Accessing this register depends on which field is being accessed; see the register field descriptions for the states that they are accessible in.

Configurations

PMDEVID is in the Debug power domain.

This register is required in all implementations.

Up until and including ARMv8.1, the architecture defines the functionality in a different set of registers, see [DBGDEVID](#).

Attributes

PMDEVID is a 32-bit register.

Field descriptions

The PMDEVID bit assignments are:

Bits [31:4]

Reserved, RES0.

PCSample, bits [3:0]

Indicates the level of PC Sample-based Profiling support using performance monitor registers. Permitted values of this field are:

- 0000 Architecture-defined form of PC Sample-based Profiling not implemented with performance monitor registers.
- 0001 Architecture-defined form of PC Sample-based Profiling is implemented with performance monitor registers.

All other values are reserved.

Accessing the PMDEVID:

PMDEVID can be accessed through the external debug interface:

Component	Offset
PMU	0xFC8

13.4.22 PMDEVTYPE, Performance Monitors Device Type register

The PMDEVTYPE characteristics are:

Purpose

Indicates to a debugger that this component is part of a PE's performance monitor interface.

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

PMDEVTYPE is in the Debug power domain.

Implementation of this register is OPTIONAL.

Attributes

PMDEVTYPE is a 32-bit register.

Field descriptions

The PMDEVTYPE bit assignments are:

Bits [31:8]

Reserved, RES0.

SUB, bits [7:4]

Subtype. Must read as 0x1 to indicate this is a component within a PE.

MAJOR, bits [3:0]

Major type. Must read as 0x6 to indicate this is a performance monitor component.

Accessing the PMDEVTYPE:

PMDEVTYPE can be accessed through the external debug interface:

Component	Offset
PMU	0xFCC

13.4.23 PMEVCNTR<n>_EL0, Performance Monitors Event Count Registers, n = 0 - 30

The PMEVCNTR<n>_EL0 characteristics are:

Purpose

Holds event counter n, which counts events, where n is 0 to 30.

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	EPMA	SLK	Default
Error	Error	Error	Error	RO	RW

External accesses to the performance monitors ignore [PMUSERENR_EL0](#) and, if implemented, [MDCR_EL2](#).{TPM, TPMCR, HPMN} and [MDCR_EL3](#).TPM. This means that all counters are accessible regardless of the current EL or privilege of the access.

Configurations

External register PMEVCNTR<n>_EL0 is architecturally mapped to AArch64 System register [PMEVCNTR<n>_EL0](#).

External register PMEVCNTR<n>_EL0 is architecturally mapped to AArch32 System register [PMEVCNTR<n>](#).

PMEVCNTR<n>_EL0 is in the Core power domain. RW fields in this register reset to architecturally UNKNOWN values. These apply on a Warm or Cold reset. The register is not affected by an External debug reset.

Attributes

PMEVCNTR<n>_EL0 is a 32-bit register.

Field descriptions

The PMEVCNTR<n>_EL0 bit assignments are:

Bits [31:0]

Event counter n. Value of event counter n, where n is the number of this register and is a number from 0 to 30.

This field resets to a value that is architecturally UNKNOWN.

Accessing the PMEVCNTR<n>_EL0:

PMEVCNTR<n>_EL0 can be accessed through the external debug interface:

Component	Offset
PMU	0x000 + 8n

13.4.24 PMEVTYPER<n>_EL0, Performance Monitors Event Type Registers, n = 0 - 30

The PMEVTYPER<n>_EL0 characteristics are:

Purpose

Configures event counter n, where n is 0 to 30.

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	EPMA	SLK	Default
Error	Error	Error	Error	RO	RW

Configurations

External register PMEVTYPER<n>_EL0 is architecturally mapped to AArch64 System register [PMEVTYPER<n>_EL0](#).

External register PMEVTYPER<n>_EL0 is architecturally mapped to AArch32 System register [PMEVTYPER<n>](#).

PMEVTYPER<n>_EL0 is in the Core power domain. RW fields in this register reset to architecturally UNKNOWN values. These apply on a Warm or Cold reset. The register is not affected by an External debug reset.

Attributes

PMEVTYPER<n>_EL0 is a 32-bit register.

Field descriptions

The PMEVTYPER<n>_EL0 bit assignments are:

P, bit [31]

Privileged filtering bit. Controls counting in EL1. If EL3 is implemented, then counting in Non-secure EL1 is further controlled by the NSK bit. The possible values of this bit are:

- 0 Count events in EL1.
- 1 Do not count events in EL1.

This field resets to a value that is architecturally UNKNOWN.

U, bit [30]

User filtering bit. Controls counting in EL0. If EL3 is implemented, then counting in Non-secure EL0 is further controlled by the NSU bit. The possible values of this bit are:

- 0 Count events in EL0.
- 1 Do not count events in EL0.

This field resets to a value that is architecturally UNKNOWN.

NSK, bit [29]

Non-secure EL1 (kernel) modes filtering bit. Controls counting in Non-secure EL1. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of P, events in Non-secure EL1 are counted.

Otherwise, events in Non-secure EL1 are not counted.

This field resets to a value that is architecturally UNKNOWN.

NSU, bit [28]

Non-secure EL0 (Unprivileged) filtering. Controls counting in Non-secure EL0. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of U, events in Non-secure EL0 are counted.

Otherwise, events in Non-secure EL0 are not counted.

This field resets to a value that is architecturally UNKNOWN.

NSH, bit [27]

Non-secure EL2 (Hypervisor) filtering. Controls counting in Non-secure EL2. If EL2 is not implemented, this bit is RES0.

0 Do not count events in EL2.

1 Count events in EL2.

This field resets to a value that is architecturally UNKNOWN.

M, bit [26]

Secure EL3 filtering bit. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of P, cycles in Secure EL3 are counted.

Otherwise, cycles in Secure EL3 are not counted.

Most applications can ignore this field and set its value to 0.

———— **Note** —————

This field is not visible in the AArch32 PMEVTYPER System register.

This field resets to a value that is architecturally UNKNOWN.

MT, bit [25]

Multithreading. When the implementation is multi-threaded, the valid values for this bit are:

0 Count events only on controlling PE.

1 Count events from any PE with the same affinity at level 1 and above as this PE.

When the implementation is not multi-threaded, this bit is RES0.

———— **Note** —————

- An implementation is described as multi-threaded when the lowest level of affinity consists of logical PEs that are implemented using a multi-threading type approach. That is, the performance of PEs at the lowest affinity level is highly interdependent. On such an implementation, the value of MPIDR_EL1.MT, when read at the highest implemented Exception level, is 1.
- Events from a different thread of a multithreaded implementation are not Attributable to the thread counting the event.

This field resets to a value that is architecturally UNKNOWN.

Bits [24:16]

Reserved, RES0.

evtCount[15:10], bits [15:10]

In ARMv8.2 and ARMv8.1

Extension to evtCount[9:0]. See evtCount[9:0] for more details.

This field resets to a value that is architecturally UNKNOWN.

In ARMv8.0.

Reserved, RES0.

evtCount[9:0], bits [9:0]

Event to count. The event number of the event that is counted by event counter [PMEVCNTR<n>_EL0](#).

Software must program this field with an event that is supported by the PE being programmed.

There are three ranges of event numbers:

- Event numbers in the range 0x000 to 0x03F are common architectural and microarchitectural events.
- Event numbers in the range 0x040 to 0x0BF are ARM recommended common architectural and microarchitectural events.
- Event numbers in the range 0x0C0 to 0x3FF are IMPLEMENTATION DEFINED events.

If evtCount is programmed to an event that is reserved or not supported by the PE, the behavior depends on the event type:

- For the range 0x000 to 0x03F, no events are counted, and the value returned by a direct or external read of the evtCount field is the value written to the field.
- For IMPLEMENTATION DEFINED events, it is UNPREDICTABLE what event, if any, is counted, and the value returned by a direct or external read of the evtCount field is UNKNOWN.

Note

UNPREDICTABLE means the event must not expose privileged information.

ARM recommends that the behavior across a family of implementations is defined such that if a given implementation does not include an event from a set of common IMPLEMENTATION DEFINED events, then no event is counted and the value read back on evtCount is the value written.

This field resets to a value that is architecturally UNKNOWN.

Accessing the PMEVTYPER<n>_EL0:

PMEVTYPER<n>_EL0 can be accessed through the external debug interface:

Component	Offset
PMU	0x400 + 4n

13.4.25 PMINTENCLR_EL1, Performance Monitors Interrupt Enable Clear register

The PMINTENCLR_EL1 characteristics are:

Purpose

Disables the generation of interrupt requests on overflows from the Cycle Count Register, [PMCCNTR_ELO](#), and the event counters [PMEVCNTR<n>_ELO](#). Reading the register shows which overflow interrupt requests are enabled.

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	EPMA	SLK	Default
Error	Error	Error	Error	RO	RW

Configurations

External register PMINTENCLR_EL1 is architecturally mapped to AArch64 System register [PMINTENCLR_EL1](#).

External register PMINTENCLR_EL1 is architecturally mapped to AArch32 System register [PMINTENCLR](#).

PMINTENCLR_EL1 is in the Core power domain. RW fields in this register reset to architecturally UNKNOWN values. These apply on a Warm or Cold reset. The register is not affected by an External debug reset.

Attributes

PMINTENCLR_EL1 is a 32-bit register.

Field descriptions

The PMINTENCLR_EL1 bit assignments are:

C, bit [31]

[PMCCNTR_ELO](#) overflow interrupt request disable bit. Possible values are:

- 0 When read, means the cycle counter overflow interrupt request is disabled. When written, has no effect.
- 1 When read, means the cycle counter overflow interrupt request is enabled. When written, disables the cycle count overflow interrupt request.

This field resets to a value that is architecturally UNKNOWN.

P<n>, bit [n], for n = 0 to 30

Event counter overflow interrupt request disable bit for [PMEVCNTR<n>_ELO](#).

Bits [30:N] are RAZ/WI. N is the value in [PMCFGR.N](#).

Possible values are:

- 0 When read, means that the [PMEVCNTR<n>_ELO](#) event counter interrupt request is disabled. When written, has no effect.
- 1 When read, means that the [PMEVCNTR<n>_ELO](#) event counter interrupt request is enabled. When written, disables the [PMEVCNTR<n>_ELO](#) interrupt request.

This field resets to a value that is architecturally UNKNOWN.

Accessing the PMINTENCLR_EL1:

PMINTENCLR_EL1 can be accessed through the external debug interface:

Component	Offset
PMU	0xC60

13.4.26 PMINTENSET_EL1, Performance Monitors Interrupt Enable Set register

The PMINTENSET_EL1 characteristics are:

Purpose

Enables the generation of interrupt requests on overflows from the Cycle Count Register, [PMCCNTR_ELO](#), and the event counters [PMEVCNTR<n>_ELO](#). Reading the register shows which overflow interrupt requests are enabled.

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	EPMA	SLK	Default
Error	Error	Error	Error	RO	RW

Configurations

External register PMINTENSET_EL1 is architecturally mapped to AArch64 System register [PMINTENSET_EL1](#).

External register PMINTENSET_EL1 is architecturally mapped to AArch32 System register [PMINTENSET](#).

PMINTENSET_EL1 is in the Core power domain. RW fields in this register reset to architecturally UNKNOWN values. These apply on a Warm or Cold reset. The register is not affected by an External debug reset.

Attributes

PMINTENSET_EL1 is a 32-bit register.

Field descriptions

The PMINTENSET_EL1 bit assignments are:

C, bit [31]

[PMCCNTR_ELO](#) overflow interrupt request enable bit. Possible values are:

- 0 When read, means the cycle counter overflow interrupt request is disabled. When written, has no effect.
- 1 When read, means the cycle counter overflow interrupt request is enabled. When written, enables the cycle count overflow interrupt request.

This field resets to a value that is architecturally UNKNOWN.

P<n>, bit [n], for n = 0 to 30

Event counter overflow interrupt request enable bit for [PMEVCNTR<n>_ELO](#).

Bits [30:N] are RAZ/WI. N is the value in [PMCFGR.N](#).

Possible values are:

- 0 When read, means that the [PMEVCNTR<n>_ELO](#) event counter interrupt request is disabled. When written, has no effect.
- 1 When read, means that the [PMEVCNTR<n>_ELO](#) event counter interrupt request is enabled. When written, enables the [PMEVCNTR<n>_ELO](#) interrupt request.

This field resets to a value that is architecturally UNKNOWN.

Accessing the PMINTENSET_EL1:

PMINTENSET_EL1 can be accessed through the external debug interface:

Component	Offset
PMU	0xC40

13.4.27 PMITCTRL, Performance Monitors Integration mode Control register

The PMITCTRL characteristics are:

Purpose

Enables the Performance Monitors to switch from default mode into integration mode, where test software can control directly the inputs and outputs of the PE, for integration testing or topology detection.

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	Default
IMP DEF	IMP DEF	IMP DEF	RW

Configurations

It is IMPLEMENTATION DEFINED whether PMITCTRL is implemented in the Core power domain or in the Debug power domain. Some or all RW fields of this register have defined reset values, and:

- The register is not affected by a Warm reset.
- If the register is implemented in the Core power domain the reset values apply on a Cold reset, and the register is not affected by an External debug reset.
- If the register is implemented in the Debug power domain the reset values apply on an External debug reset, and the register is not affected by a Cold reset.

Implementation of this register is OPTIONAL.

Attributes

PMITCTRL is a 32-bit register.

Field descriptions

The PMITCTRL bit assignments are:

Bits [31:1]

Reserved, RES0.

IME, bit [0]

Integration mode enable. When IME == 1, the device reverts to an integration mode to enable integration testing or topology detection. The integration mode behavior is IMPLEMENTATION DEFINED.

- 0 Normal operation.
- 1 Integration mode enabled.

When this register has an architecturally-defined reset value, this field resets to 0.

Accessing the PMITCTRL:

PMITCTRL can be accessed through the external debug interface:

Component	Offset
PMU	0xF00

13.4.28 PMLAR, Performance Monitors Lock Access Register

The PMLAR characteristics are:

Purpose

Allows or disallows access to the Performance Monitors registers through a memory-mapped interface.

Usage constraints

This register is accessible as follows:

Default
WO

Configurations

PMLAR is in the Debug power domain.

If OPTIONAL memory-mapped access to the external debug interface is supported then an OPTIONAL Software Lock can be implemented as part of CoreSight compliance.

PMLAR ignores writes if the Software Lock is not implemented and ignores writes for other accesses to the external debug interface.

The Software Lock provides a lock to prevent memory-mapped writes to the Performance Monitors registers. Use of this lock mechanism reduces the risk of accidental damage to the contents of the Performance Monitors registers. It does not, and cannot, prevent all accidental or malicious damage.

Software uses PMLAR to set or clear the lock, and [PMLSR](#) to check the current status of the lock.

Attributes

PMLAR is a 32-bit register.

Field descriptions

The PMLAR bit assignments are:

KEY, bits [31:0]

Lock Access control. Writing the key value 0xC5ACCE55 to this field unlocks the lock, enabling write accesses to this component's registers through a memory-mapped interface.

Writing any other value to this register locks the lock, disabling write accesses to this component's registers through a memory mapped interface.

Accessing the PMLAR:

PMLAR can be accessed through a memory-mapped interface access to the external debug interface:

Component	Offset
PMU	0xFB0

13.4.29 PMLSR, Performance Monitors Lock Status Register

The PMLSR characteristics are:

Purpose

Indicates the current status of the software lock for Performance Monitors registers.

Usage constraints

This register is accessible as follows:

Default
RO

Configurations

PMLSR is in the Debug power domain. Some or all RW fields of this register have defined reset values. These apply only on an External debug reset. The register is not affected by a Warm reset and is not affected by a Cold reset.

If OPTIONAL memory-mapped access to the external debug interface is supported then an OPTIONAL Software Lock can be implemented as part of CoreSight compliance.

PMLSR is RAZ if the Software Lock is not implemented and is RAZ for other accesses to the external debug interface.

The Software Lock provides a lock to prevent memory-mapped writes to the Performance Monitors registers. Use of this lock mechanism reduces the risk of accidental damage to the contents of the Performance Monitors registers. It does not, and cannot, prevent all accidental or malicious damage.

Software uses PMLAR to set or clear the lock, and PMLSR to check the current status of the lock.

Attributes

PMLSR is a 32-bit register.

Field descriptions

The PMLSR bit assignments are:

Bits [31:3]

Reserved, RES0.

nTT, bit [2]

Not thirty-two bit access required. RAZ.

SLK, bit [1]

Software Lock status for this component. For an access to LSR that is not a memory-mapped access, or when the Software Lock is not implemented, this field is RES0.

For memory-mapped accesses when the software lock is implemented, possible values of this field are:

- 0 Lock clear. Writes are permitted to this component's registers.
- 1 Lock set. Writes to this component's registers are ignored, and reads have no side effects.

When this register has an architecturally-defined reset value, this field resets to 1.

SLI, bit [0]

Software Lock implemented. For an access to LSR that is not a memory-mapped access, this field is RAZ. For memory-mapped accesses, the value of this field is IMPLEMENTATION DEFINED.

Permitted values are:

- 0 Software Lock not implemented or not memory-mapped access.
- 1 Software Lock implemented and memory-mapped access.

Accessing the PMLSR:

PMLSR can be accessed through a memory-mapped interface access to the external debug interface:

Component	Offset
PMU	0xFB4

13.4.30 PMOVSCLR_EL0, Performance Monitors Overflow Flag Status Clear register

The PMOVSCLR_EL0 characteristics are:

Purpose

Contains the state of the overflow bit for the Cycle Count Register, [PMCCNTR_EL0](#), and each of the implemented event counters [PMEVCNTR<n>](#). Writing to this register clears these bits.

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	EPMA	SLK	Default
Error	Error	Error	Error	RO	RW

Configurations

External register PMOVSCLR_EL0 is architecturally mapped to AArch64 System register [PMOVSCLR_EL0](#).

External register PMOVSCLR_EL0 is architecturally mapped to AArch32 System register [PMOVSR](#).

PMOVSCLR_EL0 is in the Core power domain. RW fields in this register reset to architecturally UNKNOWN values. These apply on a Warm or Cold reset. The register is not affected by an External debug reset.

Attributes

PMOVSCLR_EL0 is a 32-bit register.

Field descriptions

The PMOVSCLR_EL0 bit assignments are:

C, bit [31]

[PMCCNTR_EL0](#) overflow bit. Possible values are:

- 0 When read, means the cycle counter has not overflowed. When written, has no effect.
- 1 When read, means the cycle counter has overflowed. When written, clears the overflow bit to 0.

[PMCR_EL0](#).LC controls whether an overflow is detected from [PMCCNTR_EL0](#)[31] or from [PMCCNTR_EL0](#)[63].

This field resets to a value that is architecturally UNKNOWN.

P<n>, bit [n], for n = 0 to 30

Event counter overflow clear bit for [PMEVCNTR<n>_EL0](#).

Bits [30:N] are RAZ/WI. N is the value in [PMCFGR.N](#).

Possible values of each bit are:

- 0 When read, means that [PMEVCNTR<n>_EL0](#) has not overflowed. When written, has no effect.
- 1 When read, means that [PMEVCNTR<n>_EL0](#) has overflowed. When written, clears the [PMEVCNTR<n>_EL0](#) overflow bit to 0.

This field resets to a value that is architecturally UNKNOWN.

Accessing the PMOVSLR_EL0:

PMOVSLR_EL0 can be accessed through the external debug interface:

Component	Offset
PMU	0xC80

13.4.31 PMOVSET_EL0, Performance Monitors Overflow Flag Status Set register

The PMOVSET_EL0 characteristics are:

Purpose

Sets the state of the overflow bit for the Cycle Count Register, [PMCCNTR_EL0](#), and each of the implemented event counters [PMEVCNTR<n>](#).

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	EPMA	SLK	Default
Error	Error	Error	Error	RO	RW

Configurations

External register PMOVSET_EL0 is architecturally mapped to AArch64 System register [PMOVSET_EL0](#).

External register PMOVSET_EL0 is architecturally mapped to AArch32 System register [PMOVSET](#).

PMOVSET_EL0 is in the Core power domain. RW fields in this register reset to architecturally UNKNOWN values. These apply on a Warm or Cold reset. The register is not affected by an External debug reset.

Attributes

PMOVSET_EL0 is a 32-bit register.

Field descriptions

The PMOVSET_EL0 bit assignments are:

C, bit [31]

[PMCCNTR_EL0](#) overflow bit. Possible values are:

- 0 When read, means the cycle counter has not overflowed. When written, has no effect.
- 1 When read, means the cycle counter has overflowed. When written, sets the overflow bit to 1.

This field resets to a value that is architecturally UNKNOWN.

P<n>, bit [n], for n = 0 to 30

Event counter overflow set bit for [PMEVCNTR<n>_EL0](#).

Bits [30:N] are RAZ/WI. N is the value in [PMCFGR.N](#).

Possible values are:

- 0 When read, means that [PMEVCNTR<n>_EL0](#) has not overflowed. When written, has no effect.
- 1 When read, means that [PMEVCNTR<n>_EL0](#) has overflowed. When written, sets the [PMEVCNTR<n>_EL0](#) overflow bit to 1.

This field resets to a value that is architecturally UNKNOWN.

Accessing the PMOVSSET_EL0:

PMOVSSET_EL0 can be accessed through the external debug interface:

Component	Offset
PMU	0xCC0

13.4.32 PMPCSR, Program Counter Sample Register

The PMPCSR characteristics are:

Purpose

Holds a sampled instruction address value.

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	SLK	Default
Error	Error	Error	RO	RO

Configurations

PMPCSR is in the Core power domain.

Fields in this register reset to architecturally UNKNOWN values. These apply only on a Cold reset. The register is not affected by a Warm reset and is not affected by an External debug reset.

Implemented only if the OPTIONAL PC Sample-based Profiling Extension is implemented and [ARMv8.2-PCSample](#) is implemented.

Support for 64-bit atomic reads is IMPLEMENTATION DEFINED. If 64-bit atomic reads are implemented, a 64-bit read of PMPCSR has the same side-effect as a 32-bit read of PMCSR[31:0] followed by a 32-bit read of PMPCSR[63:32], returning the combined value. For example, if the PE is in Debug state then a 64-bit atomic read returns bits[31:0] == 0xFFFFFFFF and bits[63:32] UNKNOWN.

If the OPTIONAL PC Sample-based Profiling Extension is implemented and [ARMv8.2-PCSample](#) is not implemented, this register is not implemented and the architecture defines the functionality in [EDPCSR](#).

This register is introduced in ARMv8.2.

Attributes

PMPCSR is a 64-bit register.

Field descriptions

The PMPCSR bit assignments are:

NS, bit [63]

Non-secure state sample. Indicates the Security state that is associated with the most recent PMPCSR sample or, when it is read as a single atomic 64-bit read, the current PMPCSR sample.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

EL, bits [62:61]

Exception level status sample. Indicates the Exception level that is associated with the most recent PMPCSR sample or, when it is read as a single atomic 64-bit read, the current PMPCSR sample.

00 Sample is from EL0.

01 Sample is from EL1.

10 Sample is from EL2.

11 Sample is from EL3.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

Bits [60:56]

Reserved, RES0.

PC Sample[55:32], bits [55:32]

Bits[55:32] of the sampled instruction address value. The translation regime that PMPCSR samples can be determined from PMPCSR.{NS,EL}.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

PC Sample[31:0], bits [31:0]

Bits[31:0] of the sampled instruction address value. The translation regime that PMPCSR samples can be determined from PMPCSR.{NS,EL}.

- For a read of PMPCSR[31:0] from the memory-mapped interface, if `PMLSR.SLK == 1`, meaning the OPTIONAL Software Lock is locked, then the access has no side-effects.
- In any other cases, a read of PMPCSR[31:0] has the side-effect of indirectly writing to PMPCSR[63:32], `PMCID1SR`, `PMCID2SR`, and `PMVIDSR`:
 - If the PE is in Debug state, or PC Sample-based profiling is prohibited, PMPCSR[31:0] reads as 0xFFFFFFFF, and PMPCSR[63:32], `PMCID1SR`, `PMCID2SR`, and `PMVIDSR` become UNKNOWN.
 - If the PE is in Reset state, the sampled value is UNKNOWN and PMPCSR[63:32], `PMCID1SR`, `PMCID2SR`, and `PMVIDSR` become UNKNOWN.
 - If no instruction has been retired since the PE left Reset state, Debug state, or a state where PC Sample-based Profiling is prohibited, the sampled value is UNKNOWN, and PMPCSR[63:32], `PMCID1SR`, `PMCID2SR`, and `PMVIDSR` become UNKNOWN.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

Accessing the PMPCSR:

PMPCSR[31:0] can be accessed through the external debug interface:

Component	Offset
PMU	0x200
PMU	0x220

PMPCSR[63:32] can be accessed through the external debug interface:

Component	Offset
PMU	0x204
PMU	0x224

13.4.33 PMPIDR0, Performance Monitors Peripheral Identification Register 0

The PMPIDR0 characteristics are:

Purpose

Provides information to identify a Performance Monitor component.

For more information see [About the Peripheral identification scheme on page K2-6146](#).

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

PMPIDR0 is in the Debug power domain.

Implementation of this register is OPTIONAL.

This register is required for CoreSight compliance.

Attributes

PMPIDR0 is a 32-bit register.

Field descriptions

The PMPIDR0 bit assignments are:

Bits [31:8]

Reserved, RES0.

PART_0, bits [7:0]

Part number, least significant byte.

Accessing the PMPIDR0:

PMPIDR0 can be accessed through the external debug interface:

Component	Offset
PMU	0xFE0

13.4.34 PMPIDR1, Performance Monitors Peripheral Identification Register 1

The PMPIDR1 characteristics are:

Purpose

Provides information to identify a Performance Monitor component.

For more information see [About the Peripheral identification scheme on page K2-6146](#).

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

PMPIDR1 is in the Debug power domain.

Implementation of this register is OPTIONAL.

This register is required for CoreSight compliance.

Attributes

PMPIDR1 is a 32-bit register.

Field descriptions

The PMPIDR1 bit assignments are:

Bits [31:8]

Reserved, RES0.

DES_0, bits [7:4]

Designer, least significant nibble of JEP106 ID code. For ARM Limited, this field is 0b1011.

PART_1, bits [3:0]

Part number, most significant nibble.

Accessing the PMPIDR1:

PMPIDR1 can be accessed through the external debug interface:

Component	Offset
PMU	0xFE4

13.4.35 PMPIDR2, Performance Monitors Peripheral Identification Register 2

The PMPIDR2 characteristics are:

Purpose

Provides information to identify a Performance Monitor component.

For more information see [About the Peripheral identification scheme on page K2-6146](#).

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

PMPIDR2 is in the Debug power domain.

Implementation of this register is OPTIONAL.

This register is required for CoreSight compliance.

Attributes

PMPIDR2 is a 32-bit register.

Field descriptions

The PMPIDR2 bit assignments are:

Bits [31:8]

Reserved, RES0.

REVISION, bits [7:4]

Part major revision. Parts can also use this field to extend Part number to 16-bits.

JEDEC, bit [3]

RAO. Indicates a JEP106 identity code is used.

DES_1, bits [2:0]

Designer, most significant bits of JEP106 ID code. For ARM Limited, this field is 0b011.

Accessing the PMPIDR2:

PMPIDR2 can be accessed through the external debug interface:

Component	Offset
PMU	0xFE8

13.4.36 PMPIDR3, Performance Monitors Peripheral Identification Register 3

The PMPIDR3 characteristics are:

Purpose

Provides information to identify a Performance Monitor component.

For more information see [About the Peripheral identification scheme on page K2-6146](#).

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

PMPIDR3 is in the Debug power domain.

Implementation of this register is OPTIONAL.

This register is required for CoreSight compliance.

Attributes

PMPIDR3 is a 32-bit register.

Field descriptions

The PMPIDR3 bit assignments are:

Bits [31:8]

Reserved, RES0.

REVAND, bits [7:4]

Part minor revision. Parts using [PMPIDR2.REVISION](#) as an extension to the Part number must use this field as a major revision number.

CMOD, bits [3:0]

Customer modified. Indicates someone other than the Designer has modified the component.

Accessing the PMPIDR3:

PMPIDR3 can be accessed through the external debug interface:

Component	Offset
PMU	0xFEC

13.4.37 PMPIDR4, Performance Monitors Peripheral Identification Register 4

The PMPIDR4 characteristics are:

Purpose

Provides information to identify a Performance Monitor component.

For more information see [About the Peripheral identification scheme on page K2-6146](#).

Usage constraints

This register is accessible as follows:

SLK	Default
RO	RO

Configurations

PMPIDR4 is in the Debug power domain.

Implementation of this register is OPTIONAL.

This register is required for CoreSight compliance.

Attributes

PMPIDR4 is a 32-bit register.

Field descriptions

The PMPIDR4 bit assignments are:

Bits [31:8]

Reserved, RES0.

SIZE, bits [7:4]

Size of the component. RAZ. \log_2 of the number of 4KB pages from the start of the component to the end of the component ID registers.

DES_2, bits [3:0]

Designer, JEP106 continuation code, least significant nibble. For ARM Limited, this field is 0b0100.

Accessing the PMPIDR4:

PMPIDR4 can be accessed through the external debug interface:

Component	Offset
PMU	0xFD0

13.4.38 PMSWINC_EL0, Performance Monitors Software Increment register

The PMSWINC_EL0 characteristics are:

Purpose

Increments a counter that is configured to count the Software increment event, event 0x00. For more information, see [SW_INCR](#).

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	EPMAD	SLK	Default
Error	Error	Error	Error	WI	WO

Configurations

External register PMSWINC_EL0 is architecturally mapped to AArch64 System register [PMSWINC_EL0](#).

External register PMSWINC_EL0 is architecturally mapped to AArch32 System register [PMSWINC](#).

PMSWINC_EL0 is in the Core power domain.

Implementation of this register is OPTIONAL.

If this register is implemented, use of it is deprecated.

If 1 is written to bit [n] from the external debug interface, it is CONstrained UNPREDICTABLE whether or not a SW_INCR event is created for counter n. This is consistent with not implementing the register in the external debug interface.

Attributes

PMSWINC_EL0 is a 32-bit register.

Field descriptions

The PMSWINC_EL0 bit assignments are:

Bit [31]

Reserved, RES0.

P<n>, bit [n], for n = 0 to 30

Event counter software increment bit for [PMEVCNTR<n>_EL0](#).

P<n> is WI if n >= [PMCR_EL0.N](#), the number of implemented counters.

Otherwise, the effects of writing to this bit are:

- 0 No action. The write to this bit is ignored.
- 1 It is CONstrained UNPREDICTABLE whether a SW_INCR event is generated for event counter n.

Accessing the PMSWINC_EL0:

PMSWINC_EL0 can be accessed through the external debug interface:

Component	Offset
PMU	0xCA0

13.4.39 PMVIDSR, VMID Sample Register

The PMVIDSR characteristics are:

Purpose

Contains the sampled VMID value that is captured on reading [PMPCSR](#)[31:0].

Usage constraints

This register is accessible as follows:

Off	DLK	OSLK	SLK	Default
Error	Error	Error	RO	RO

Configurations

PMVIDSR is in the Core power domain.

Fields in this register reset to architecturally UNKNOWN values. These apply only on a Cold reset. The register is not affected by a Warm reset and is not affected by an External debug reset.

Implemented only if the OPTIONAL PC Sample-based Profiling Extension is implemented and [ARMv8.2-PCSample](#) is implemented. If the OPTIONAL PC Sample-based Profiling Extension is implemented and [ARMv8.2-PCSample](#) is not implemented, this register is not implemented and the architecture defines the functionality in [EDVIDSR](#).

If EL2 is not implemented, this register is RES0.

This register is introduced in ARMv8.2.

Attributes

PMVIDSR is a 32-bit register.

Field descriptions

The PMVIDSR bit assignments are:

Bits [31:16]

Reserved, RES0.

VMID, bits [15:0]

VMID sample. The VMID associated with the most recent [PMPCSR](#) sample.

- If EL2 is implemented and is using AArch64, then the VMID is held in [VTTBR_EL2](#).VMID.
- If EL2 is implemented and is using AArch32, then the VMID is held in [VTTBR](#).VMID.
- This field is set to an UNKNOWN value if:
 - [PMPCSR](#).NS == 0.
 - [PMPCSR](#).EL == 0b10.
 - [PMPCSR](#).NS == 1, [PMPCSR](#).EL == 0b00, EL2 is using AArch64, [HCR_EL2](#).E2H == 1, and [HCR_EL2](#).TGE == 1.
- If EL2 is not implemented, then this field is RES0.
- If 16-bit VMIDs are not supported, [PMVIDSR](#).VMID[15:8] is RES0.

- If 16-bit VMIDs are supported, but VTTBRx.VMID[15:8] are not used, PMVIDSR.VMID[15:8] is set to 0.

When this register has an architecturally-defined reset value, this field resets to a value that is architecturally UNKNOWN.

Accessing the PMVIDSR:

PMVIDSR can be accessed through the external debug interface:

Component	Offset
PMU	0x20C

I3.5 Generic Timer memory-mapped registers overview

The Generic Timer memory-mapped registers are implemented as multiple register frames, with each register frame having its own base address, as follows:

- A single CNTCTLBase register frame, at base address CNTCTLBase.
- Between one and seven CNTBaseN register frames, each with its own base address CNTBaseN.
- For each CNTBaseN register frame, if required, a CNTEL0BaseN register frame, at base address CNTEL0BaseN, that provides an EL0 view of the CNTBaseN register frame.

For more information, see:

- [Memory-mapped timer components on page I1-5730.](#)
- [The CNTBaseN and CNTEL0BaseN frames on page I1-5732.](#) This section includes the memory map of the CNTBaseN and CNTEL0BaseN register frames.
- [The CNTCTLBase frame on page I1-5731.](#) This section includes the memory map of the CNTCTLBase register frame.
- [Providing a complete set of counter and timer features on page I1-5734.](#)

I3.6 Generic Timer memory-mapped register descriptions

This section describes the Generic Timer registers. [Generic Timer memory-mapped registers overview on page I3-5815](#) gives an overview of these registers, and includes links to their memory maps.

13.6.1 CNTACR<n>, Counter-timer Access Control Registers, n = 0 - 7

The CNTACR<n> characteristics are:

Purpose

Provides top-level access controls for the elements of a timer frame. CNTACR<n> provides the controls for frame CNTBaseN.

In addition to the CNTACR<n> control:

- CNTNSAR controls whether CNTACR<n> is accessible by Non-secure accesses.
- If frame CNTELOBaseN is implemented, the CNTELOACR in frame CNTBaseN provides additional control of accesses to frame CNTELOBaseN.

Usage constraints

This register is accessible as follows:

Default

RW

In a system that recognizes two Security states:

- CNTACR<n> is always accessible by Secure accesses.
- CNTNSAR.NS<n> determines whether CNTACR<n> is accessible by Non-secure accesses.

Configurations

The power domain of CNTACR<n> is IMPLEMENTATION DEFINED.

On a reset of the reset domain in which it is implemented, RW fields in this register reset to UNKNOWN values. The register is not affected by a reset of any other reset domain. For more information see [Power and reset domains for the system level implementation of the Generic Timer on page I1-5724](#).

Implemented only if the value of CNTTIDR.Frame<n> is 1.

An implementation of the counters might not provide configurable access to some or all of the features. In this case, the associated field in the CNTACR<n> register is:

- RAZ/WI if access is always denied.
- RAO/WI if access is always permitted.

Attributes

CNTACR<n> is a 32-bit register.

Field descriptions

The CNTACR<n> bit assignments are:

Bits [31:6]

Reserved, RES0.

RWPT, bit [5]

Read/write access to the EL1 Physical Timer registers [CNTP_CVAL](#), [CNTP_TVAL](#), and [CNTP_CTL](#), in frame <n>. The possible values of this bit are:

- 0 No access to the EL1 Physical Timer registers in frame <n>. The registers are RES0.
- 1 Read/write access to the EL1 Physical Timer registers in frame <n>.

RWVT, bit [4]

Read/write access to the Virtual Timer register [CNTV_CVAL](#), [CNTV_TVAL](#), and [CNTV_CTL](#), in frame <n>. The possible values of this bit are:

- 0 No access to the Virtual Timer registers in frame <n>. The registers are RES0.
- 1 Read/write access to the Virtual Timer registers in frame <n>.

RVOFF, bit [3]

Read-only access to [CNTVOFF](#), in frame <n>. The possible values of this bit are:

- 0 No access to [CNTVOFF](#) in frame <n>. The register is RES0.
- 1 Read-only access to [CNTVOFF](#) in frame <n>.

RFrq, bit [2]

Read-only access to [CNTFRQ](#), in frame <n>. The possible values of this bit are:

- 0 No access to [CNTFRQ](#) in frame <n>. The register is RES0.
- 1 Read-only access to [CNTFRQ](#) in frame <n>.

RVCT, bit [1]

Read-only access to [CNTVCT](#), in frame <n>. The possible values of this bit are:

- 0 No access to [CNTVCT](#) in frame <n>. The register is RES0.
- 1 Read-only access to [CNTVCT](#) in frame <n>.

RPCT, bit [0]

Read-only access to [CNTPCT](#), in frame <n>. The possible values of this bit are:

- 0 No access to [CNTPCT](#) in frame <n>. The register is RES0.
- 1 Read-only access to [CNTPCT](#) in frame <n>.

Accessing the CNTACR<n>:

CNTACR<n> can be accessed through its memory-mapped interface:

Component	Frame	Offset
Timer	CNTCTLBase	0x040 + 4n

13.6.2 CNTCR, Counter Control Register

The CNTCR characteristics are:

Purpose

Enables the counter, controls the counter frequency setting, and controls counter behavior during debug.

Usage constraints

This register is accessible as follows:

Default

RW

In a system that supports Secure and Non-secure memory maps the CNTControlBase frame, that includes this register, is implemented only in the Secure memory map.

Configurations

The power domain of CNTCR is IMPLEMENTATION DEFINED.

Some or all fields in this register have defined reset values. These apply only on a reset of the reset domain in which the register is implemented. The register is not affected by a reset of any other reset domain. For more information see [Power and reset domains for the system level implementation of the Generic Timer](#) on page I1-5724.

Attributes

CNTCR is a 32-bit register.

Field descriptions

The CNTCR bit assignments are:

Bits [31:18]

Reserved, RES0.

FCREQ, bits [17:8]

Frequency change request. Indicates the number of the entry in the Frequency modes table to select. Selecting an unimplemented entry, or an entry that contains 0, has no effect on the counter.

The maximum number of entries in the Frequency modes table is IMPLEMENTATION DEFINED up to a maximum of 1004 entries, see [The Frequency modes table](#) on page I1-5727. An implementation is only required to implement an FCREQ field that can hold values from 0 to the highest supported Frequency modes table entry. Any unrequired most-significant bits of FCREQ can be implemented as RES0.

When this register has an architecturally-defined reset value, this field resets to 0.

Bits [7:2]

Reserved, RES0.

HDBG, bit [1]

Halt-on-debug. Controls whether a Halt-on-debug signal halts the system counter:

- 0 System counter ignores Halt-on-debug.
- 1 Asserted Halt-on-debug signal halts system counter update.

This field resets to a value that is architecturally UNKNOWN.

EN, bit [0]

Enables the counter:

- 0 System counter disabled.
- 1 System counter enabled.

When this register has an architecturally-defined reset value, this field resets to 0.

Accessing the CNTCR:

CNTCR can be accessed through its memory-mapped interface:

Component	Frame	Offset
Timer	CNTControlBase	0x000

I3.6.3 CNTCV, Counter Count Value register

The CNTCV characteristics are:

Purpose

Indicates the current count value.

Usage constraints

This register is accessible as follows:

Frame	Accessibility
CNTControlBase	RW
CNTReadBase	RO

A write to CNTCV must be visible in the [CNTPCT](#) register of each running processor in a finite time.

For the instance of the register in the CNTControlBase frame:

- In a system that supports Secure and Non-secure memory maps the CNTControlBase frame, and therefore this register instance, is implemented only in the Secure memory map.
- If the counter is enabled, the effect of writing to the register is UNKNOWN.

In an implementation that supports 64-bit atomic memory accesses, this register must be accessible using a 64-bit atomic access.

Configurations

The power domain of CNTCV is IMPLEMENTATION DEFINED.

On a reset of the reset domain in which an RW instance of this register is implemented, RW fields in the register reset to UNKNOWN values. The register is not affected by a reset of any other reset domain. For more information see [Power and reset domains for the system level implementation of the Generic Timer](#) on page I1-5724.

Attributes

CNTCV is a 64-bit register.

Field descriptions

The CNTCV bit assignments are:

CountValue, bits [63:0]

Indicates the counter value.

Accessing the CNTCV:

CNTCV[31:0] can be accessed through its memory-mapped interface:

Component	Frame	Offset
Timer	CNTControlBase	0x008
Timer	CNTReadBase	0x000

CNTCV[63:32] can be accessed through its memory-mapped interface:

Component	Frame	Offset
Timer	CNTControlBase	0x00C
Timer	CNTReadBase	0x004

13.6.4 CNTEL0ACR, Counter-timer EL0 Access Control Register

The CNTEL0ACR characteristics are:

Purpose

An implementation of CNTEL0ACR in the frame at CNTBaseN controls whether the [CNTPCT](#), [CNTVCT](#), [CNTFRQ](#), EL1 Physical Timer, and Virtual Timer registers are visible in the frame at CNTEL0BaseN.

Usage constraints

CNTEL0ACR can be implemented in any implemented CNTBaseN frame.

[CNTCTLBase status and control fields for the CNTBaseN and CNTEL0BaseN frames on page I1-5733](#) describes the status fields that identify whether a CNTBaseN frame is implemented, and for an implemented frame:

- Whether the CNTBaseN frame has virtual timer capability.
- Whether the corresponding CNTEL0BaseN frame is implemented.
- For an implementation that recognizes two Security states, whether the CNTBaseN frame, and any corresponding CNTEL0BaseN frame, is accessible by Non-secure accesses.

If CNTEL0ACR is not implemented in an implemented CNTBaseN frame:

- The register location in that frame is RAZ/WI.
- If the corresponding CNTEL0BaseN frame is implemented, the registers [CNTFRQ](#), [CNTP_CTL](#), [CNTP_CVAL](#), [CNTP_TVAL](#), [CNTPCT](#), [CNTV_CTL](#), [CNTV_CVAL](#), [CNTV_TVAL](#), and [CNTVCT](#) are not visible in that frame.

Configurations

The power domain of CNTEL0ACR is IMPLEMENTATION DEFINED.

On a reset of the reset domain in which it is implemented, RW fields in this register reset to UNKNOWN values. The register is not affected by a reset of any other reset domain. For more information see [Power and reset domains for the system level implementation of the Generic Timer on page I1-5724](#).

Implementation of this register is OPTIONAL.

Attributes

CNTEL0ACR is a 32-bit register.

Field descriptions

The CNTEL0ACR bit assignments are:

Bits [31:10]

Reserved, RES0.

EL0PTEN, bit [9]

Second view read/write access control for the EL1 Physical Timer registers. This bit controls whether the [CNTP_CVAL](#), [CNTP_TVAL](#), and [CNTP_CTL](#) registers in the current CNTBaseN frame are also accessible in the corresponding CNTELOBaseN frame. The possible values of this bit are:

- 0 No access. Registers are RES0 in the second view.
- 1 Access permitted. If the registers are accessible in the current frame then they are accessible in the second view.

EL0VTEN, bit [8]

Second view read/write access control for the Virtual Timer registers. This bit controls whether the [CNTV_CVAL](#), [CNTV_TVAL](#), and [CNTV_CTL](#) registers in the current CNTBaseN frame are also accessible in the corresponding CNTELOBaseN frame. The possible values of this bit are:

- 0 No access. Registers are RES0 in the second view.
- 1 Access permitted. If the registers are accessible in the current frame then they are accessible in the second view.

The definition of this bit means that, if the Virtual Timer registers are not implemented in the current CNTBaseN frame, then the Virtual Timer register addresses are RES0 in the corresponding CNTELOBaseN frame, regardless of the value of this bit.

Bits [7:2]

Reserved, RES0.

EL0VCTEN, bit [1]

Second view read access control for [CNTVCT](#) and [CNTFRQ](#). The possible values of this bit are:

- 0 [CNTVCT](#) is not visible in the second view.
If EL0PCTEN is set to 0, [CNTFRQ](#) is not visible in the second view.
- 1 Access permitted. If [CNTVCT](#) and [CNTFRQ](#) are visible in the current frame then they are visible in the second view.

EL0PCTEN, bit [0]

Second view read access control for [CNTPCT](#) and [CNTFRQ](#). The possible values of this bit are:

- 0 [CNTPCT](#) is not visible in the second view.
If EL0VCTEN is set to 0, [CNTFRQ](#) is not visible in the second view.
- 1 Access permitted. If [CNTPCT](#) and [CNTFRQ](#) are visible in the current frame then they are visible in the second view.

Accessing the CNTELOACR:

CNTELOACR can be accessed through its memory-mapped interface:

Component	Frame	Accessibility	Offset
Timer	CNTBaseN	RW	0x014

13.6.5 CNTFID0, Counter Frequency ID

The CNTFID0 characteristics are:

Purpose

Indicates the base frequency of the system counter.

Usage constraints

This register is accessible as follows:

Default

RO or RW

In a system that supports Secure and Non-secure memory maps the CNTControlBase frame, that includes this register, is implemented only in the Secure memory map.

Configurations

The power domain of CNTFID0 is IMPLEMENTATION DEFINED.

If this register is implemented as an RW register, on a reset of the reset domain in which it is implemented, RW fields in this register reset to UNKNOWN values. The register is not affected by a reset of any other reset domain. For more information see [Power and reset domains for the system level implementation of the Generic Timer on page 11-5724](#).

The possible frequencies for the system counter are stored in the Frequency modes table as 32-bit words starting with the base frequency, CNTFID0. For more information see [The Frequency modes table on page 11-5727](#).

The final entry in the Frequency modes table must be followed by a 32-bit word of zero value, to mark the end of the table.

Typically, the Frequency modes table will be in read-only memory. However, a system implementation might use read/write memory for the table, and initialize the table entries as part of its start-up sequence.

If the Frequency modes table is in read/write memory, ARM strongly recommends that the table is not updated once the system is running.

Attributes

CNTFID0 is a 32-bit register.

Field descriptions

The CNTFID0 bit assignments are:

Frequency, bits [31:0]

The base frequency of the system counter, in Hz.

Accessing the CNTFID0:

CNTFID0 can be accessed through its memory-mapped interface:

Component	Frame	Offset
Timer	CNTControlBase	0x020

13.6.6 CNTFID<n>, Counter Frequency IDs, n > 0

The CNTFID<n> characteristics are:

Purpose

Indicates alternative system counter update frequencies.

Usage constraints

This register is accessible as follows:

Default

RO or RW

In a system that supports Secure and Non-secure memory maps the CNTControlBase frame, that includes these registers, is implemented only in the Secure memory map.

Configurations

The power domain of CNTFID<n> is IMPLEMENTATION DEFINED.

If this register is implemented as an RW register, on a reset of the reset domain in which it is implemented, RW fields in this register reset to UNKNOWN values. The register is not affected by a reset of any other reset domain. For more information see *Power and reset domains for the system level implementation of the Generic Timer* on page 11-5724.

The possible frequencies for the system counter are stored in the Frequency modes table as 32-bit words starting with the base frequency, CNTFID0, see *The Frequency modes table* on page 11-5727.

The number of CNTFID<n> registers is IMPLEMENTATION DEFINED, and the only required CNTFID<n> register is CNTFID0.

The final entry in the Frequency modes table must be followed by a 32-bit word of zero value, to mark the end of the table.

Typically, the Frequency modes table will be in read-only memory. However, a system implementation might use read/write memory for the table, and initialize the table entries as part of its start-up sequence.

If the Frequency modes table is in read/write memory, ARM strongly recommends that the table is not updated once the system is running.

Attributes

CNTFID<n> is a 32-bit register.

Field descriptions

The CNTFID<n> bit assignments are:

Frequency, bits [31:0]

A system counter update frequency, in Hz. Must be an exact divisor of the base frequency. ARM strongly recommends that all frequency values in the Frequency modes table are integer power-of-two divisors of the base frequency.

When the system timer is operating at a lower frequency than the base frequency, the increment applied at each counter update is given by:

$$\text{increment} = (\text{base frequency}) / (\text{selected frequency})$$

Accessing the CNTFID<n>:

CNTFID<n> can be accessed through its memory-mapped interface:

Component	Frame	Offset
Timer	CNTControlBase	0x020 + 4n

13.6.7 CNTFRQ, Counter-timer Frequency

The CNTFRQ characteristics are:

Purpose

This register is provided so that software can discover the frequency of the system counter. The instance of this register in the CNTCTLBase frame must be programmed with this value as part of system initialization. The value of the register is not interpreted by hardware.

Usage constraints

CNTFRQ must be implemented as an RW register in the CNTCTLBase frame.

In a system that recognizes two Security states, the instance of this register in the CNTCTLBase frame is only accessible by Secure accesses.

CNTFRQ can be implemented as a RO register in any implemented CNTBaseN frame, and in the corresponding CNTEL0BaseN frame.

CNTCTLBase status and control fields for the CNTBaseN and CNTEL0BaseN frames on page I1-5733 describes the status fields that identify whether a CNTBaseN frame is implemented, and for an implemented frame:

- Whether the CNTBaseN frame has virtual timer capability.
- Whether the corresponding CNTEL0BaseN frame is implemented.
- For an implementation that recognizes two Security states, whether the CNTBaseN frame, and any corresponding CNTEL0BaseN frame, is accessible by Non-secure accesses.

For an implemented CNTBaseN frame:

- CNTFRQ is accessible in that frame, as a RO register, if the value of CNTACR<n>.RFRQ is 1.
- Otherwise, the CNTFRQ address in that frame is RAZ/WI.

For an implemented CNTEL0BaseN frame:

- CNTFRQ is accessible in that frame if both:
 - CNTFRQ is accessible in the corresponding CNTBaseN frame.
 - The value of at least one of CNTEL0ACR.ELOVCTEN and CNTEL0ACR.ELOPCTEN is 1.
- Otherwise, the CNTFRQ address in that frame is RAZ/WI.

Configurations

The power domain of CNTFRQ is IMPLEMENTATION DEFINED.

On a reset of the reset domain in which an RW instance of this register is implemented, RW fields in the register reset to UNKNOWN values. The register is not affected by a reset of any other reset domain. For more information see *Power and reset domains for the system level implementation of the Generic Timer on page I1-5724*.

Attributes

CNTFRQ is a 32-bit register.

Field descriptions

The CNTFRQ bit assignments are:

Bits [31:0]

Clock frequency. Indicates the system counter clock frequency, in Hz.

Accessing the CNTFRQ:

CNTFRQ can be accessed through its memory-mapped interface:

Component	Frame	Accessibility	Offset
Timer	CNTBaseN	RW	0x010
Timer	CNTEL0BaseN	RO	0x010
Timer	CNTCTLBase	RO	0x000

13.6.8 CNTNSAR, Counter-timer Non-secure Access Register

The CNTNSAR characteristics are:

Purpose

Provides the highest-level control of whether frames CNTBaseN and CNTEL0BaseN are accessible by Non-secure accesses.

Usage constraints

This register is accessible as follows:

Default
RW

In a system that recognizes two Security states, this register is only accessible by Secure accesses.

Configurations

The power domain of CNTNSAR is IMPLEMENTATION DEFINED.

On a reset of the reset domain in which it is implemented, RW fields in this register reset to UNKNOWN values. The register is not affected by a reset of any other reset domain. For more information see *Power and reset domains for the system level implementation of the Generic Timer* on page I1-5724.

Attributes

CNTNSAR is a 32-bit register.

Field descriptions

The CNTNSAR bit assignments are:

Bits [31:8]

Reserved, RES0.

NS<n>, bit [n], for n = 0 to 7

Non-secure access to frame n. The possible values of this bit are:

- 0 Secure access only. Behaves as RES0 to Non-secure accesses.
- 1 Secure and Non-secure accesses permitted.

This bit also determines whether, in the CNTCTLBase frame, CNTACR<n> and CNTVOFF<n> are accessible to Non-secure accesses.

If frame CNTBase<n>:

- Is not implemented, then NS<n> is RES0.
- Is not Configurable access, and is accessible only by Secure accesses, then NS<n> is RES0.
- Is not Configurable access, and is accessible by both Secure and Non-secure accesses, then NS<n> is RES1.

Accessing the CNTNSAR:

CNTNSAR can be accessed through its memory-mapped interface:

Component	Frame	Offset
Timer	CNTCTLBase	0x004

13.6.9 CNTP_CTL, Counter-timer Physical Timer Control

The CNTP_CTL characteristics are:

Purpose

Control register for the physical timer.

Usage constraints

CNTP_CTL can be implemented in any implemented CNTBaseN frame, and in the corresponding CNTELOBaseN frame.

CNTCTLBase status and control fields for the CNTBaseN and CNTELOBaseN frames on page I1-5733 describes the status fields that identify whether a CNTBaseN frame is implemented, and for an implemented frame:

- Whether the CNTBaseN frame has virtual timer capability.
- Whether the corresponding CNTELOBaseN frame is implemented.
- For an implementation that recognizes two Security states, whether the CNTBaseN frame, and any corresponding CNTELOBaseN frame, is accessible by Non-secure accesses.

For an implemented CNTBaseN frame:

- CNTP_CTL is accessible in that frame if the value of CNTACR<n>.RWPT is 1.
- Otherwise, the CNTP_CTL address in that frame is RAZ/WI.

For an implemented CNTELOBaseN frame:

- CNTP_CTL is accessible in that frame if both:
 - CNTP_CTL is accessible in the corresponding CNTBaseN frame.
 - The value of CNTELOACR.ELOPTEN is 1.
- Otherwise, the CNTP_CTL address in that frame is RAZ/WI.

Configurations

The power domain of CNTP_CTL is IMPLEMENTATION DEFINED.

On a reset of the reset domain in which an RW instance of this register is implemented, RW fields in the register reset to UNKNOWN values. The register is not affected by a reset of any other reset domain. For more information see *Power and reset domains for the system level implementation of the Generic Timer on page I1-5724*.

Attributes

CNTP_CTL is a 32-bit register.

Field descriptions

The CNTP_CTL bit assignments are:

Bits [31:3]

Reserved, RES0.

ISTATUS, bit [2]

The status of the timer. This bit indicates whether the timer condition is met:

- 0 Timer condition is not met.
- 1 Timer condition is met.

When the value of the ENABLE bit is 1, ISTATUS indicates whether the timer condition is met. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0 then the timer interrupt is asserted.

When the value of the ENABLE bit is 0, the ISTATUS field is UNKNOWN.

For more information see [Operation of the CompareValue views of the timers on page D6-2187](#) and [Operation of the TimerValue views of the timers on page D6-2188](#).

This bit is read-only.

IMASK, bit [1]

Timer interrupt mask bit. Permitted values are:

- 0 Timer interrupt is not masked by the IMASK bit.
- 1 Timer interrupt is masked by the IMASK bit.

For more information, see the description of the ISTATUS bit.

ENABLE, bit [0]

Enables the timer. Permitted values are:

- 0 Timer disabled.
- 1 Timer enabled.

Setting this bit to 0 disables the timer output signal, but the timer value accessible from [CNTP_TVAL](#) continues to count down.

———— **Note** —————

Disabling the output signal might be a power-saving option.

Accessing the CNTP_CTL:

CNTP_CTL can be accessed through its memory-mapped interface:

Component	Frame	Accessibility	Offset
Timer	CNTBaseN	RW	0x02C
Timer	CNTELOBaseN	RW	0x02C

13.6.10 CNTP_CVAL, Counter-timer Physical Timer CompareValue

The CNTP_CVAL characteristics are:

Purpose

Holds the 64-bit compare value for the EL1 physical timer.

Usage constraints

CNTP_CVAL can be implemented in any implemented CNTBaseN frame, and in the corresponding CNTELOBaseN frame.

CNTCTLBase status and control fields for the CNTBaseN and CNTELOBaseN frames on page I1-5733 describes the status fields that identify whether a CNTBaseN frame is implemented, and for an implemented frame:

- Whether the CNTBaseN frame has virtual timer capability.
- Whether the corresponding CNTELOBaseN frame is implemented.
- For an implementation that recognizes two Security states, whether the CNTBaseN frame, and any corresponding CNTELOBaseN frame, is accessible by Non-secure accesses.

For an implemented CNTBaseN frame:

- CNTP_CVAL is accessible in that frame if the value of CNTACR<n>.RWPT is 1.
- Otherwise, the CNTP_CVAL address in that frame is RAZ/WI.

For an implemented CNTELOBaseN frame:

- CNTP_CVAL is accessible in that frame if both:
 - CNTP_CVAL is accessible in the corresponding CNTBaseN frame.
 - The value of CNTELOACR.ELOPTEN is 1.
- Otherwise, the CNTP_CVAL address in that frame is RAZ/WI.

If the implementation supports 64-bit atomic accesses, then the CNTP_CVAL register must be accessible as an atomic 64-bit value.

Configurations

The power domain of CNTP_CVAL is IMPLEMENTATION DEFINED.

On a reset of the reset domain in which an RW instance of this register is implemented, RW fields in the register reset to UNKNOWN values. The register is not affected by a reset of any other reset domain. For more information see *Power and reset domains for the system level implementation of the Generic Timer on page I1-5724*.

Attributes

CNTP_CVAL is a 64-bit register.

Field descriptions

The CNTP_CVAL bit assignments are:

CompareValue, bits [63:0]

Holds the EL1 physical timer CompareValue.

When CNTP_CTL.ENABLE is 1, the timer condition is met when (CNTPCT - CompareValue) is greater than zero. This means that CompareValue acts like a 64-bit upcounter timer. When the timer condition is met:

- CNTP_CTL.ISTATUS is set to 1.

- An interrupt is generated if `CNTP_CTL.IMASK` is 0.
When `CNTP_CTL.ENABLE` is 0, the timer condition is not met, but `CNTPCT` continues to count.

Accessing the `CNTP_CVAL`:

`CNTP_CVAL[31:0]` can be accessed through its memory-mapped interface:

Component	Frame	Accessibility	Offset
Timer	<code>CNTBaseN</code>	RW	<code>0x020</code>
Timer	<code>CNTELOBaseN</code>	RW	<code>0x020</code>

`CNTP_CVAL[63:32]` can be accessed through its memory-mapped interface:

Component	Frame	Accessibility	Offset
Timer	<code>CNTBaseN</code>	RW	<code>0x024</code>
Timer	<code>CNTELOBaseN</code>	RW	<code>0x024</code>

I3.6.11 CNTP_TVAL, Counter-timer Physical Timer TimerValue

The CNTP_TVAL characteristics are:

Purpose

Holds the timer value for the EL1 physical timer.

Usage constraints

CNTP_TVAL can be implemented in any implemented CNTBaseN frame, and in the corresponding CNTELOBaseN frame.

CNTCTLBase status and control fields for the CNTBaseN and CNTELOBaseN frames on page I1-5733 describes the status fields that identify whether a CNTBaseN frame is implemented, and for an implemented frame:

- Whether the CNTBaseN frame has virtual timer capability.
- Whether the corresponding CNTELOBaseN frame is implemented.
- For an implementation that recognizes two Security states, whether the CNTBaseN frame, and any corresponding CNTELOBaseN frame, is accessible by Non-secure accesses.

For an implemented CNTBaseN frame:

- CNTP_TVAL is accessible in that frame if the value of CNTACR<n>.RWPT is 1.
- Otherwise, the CNTP_TVAL address in that frame is RAZ/WI.

For an implemented CNTELOBaseN frame:

- CNTP_TVAL is accessible in that frame if both:
 - CNTP_TVAL is accessible in the corresponding CNTBaseN frame.
 - The value of CNTELOACR.ELOPTEN is 1.
- Otherwise, the CNTP_TVAL address in that frame is RAZ/WI.

Configurations

The power domain of CNTP_TVAL is IMPLEMENTATION DEFINED.

On a reset of the reset domain in which an RW instance of this register is implemented, RW fields in the register reset to UNKNOWN values. The register is not affected by a reset of any other reset domain. For more information see *Power and reset domains for the system level implementation of the Generic Timer on page I1-5724*.

Attributes

CNTP_TVAL is a 32-bit register.

Field descriptions

The CNTP_TVAL bit assignments are:

TimerValue, bits [31:0]

The TimerValue view of the EL1 physical timer.

On a read of this register:

- If CNTP_CTL.ENABLE is 0, the value returned is UNKNOWN.
- If CNTP_CTL.ENABLE is 1, the value returned is (CompareValue - CNTPCT).

On a write of this register, CompareValue is set to (CNTPCT + TimerValue), where TimerValue is treated as a signed 32-bit integer.

When `CNTP_CTL.ENABLE` is 1, the timer condition is met when $(\text{CNTPCT} - \text{CompareValue})$ is greater than zero. This means that `TimerValue` acts like a 32-bit downcounter timer. When the timer condition is met:

- `CNTP_CTL.ISTATUS` is set to 1.
- If `CNTP_CTL.IMASK` is 0, an interrupt is generated.

When `CNTP_CTL.ENABLE` is 0, the timer condition is not met, but `CNTPCT` continues to count, so the `TimerValue` view appears to continue to count down.

Accessing the `CNTP_TVAL`:

`CNTP_TVAL` can be accessed through its memory-mapped interface:

Component	Frame	Accessibility	Offset
Timer	CNTBaseN	RW	0x028
Timer	CNTELOBaseN	RW	0x028

13.6.12 CNTPCT, Counter-timer Physical Count

The CNTPCT characteristics are:

Purpose

Holds the 64-bit physical count value.

Usage constraints

CNPCT can be implemented in any implemented CNTBaseN frame, and in the corresponding CNTELOBaseN frame, as a RO register.

CNCTLBase status and control fields for the CNTBaseN and CNTELOBaseN frames on page I1-5733 describes the status fields that identify whether a CNTBaseN frame is implemented, and for an implemented frame:

- Whether the CNTBaseN frame has virtual timer capability.
- Whether the corresponding CNTELOBaseN frame is implemented.
- For an implementation that recognizes two Security states, whether the CNTBaseN frame, and any corresponding CNTELOBaseN frame, is accessible by Non-secure accesses.

For an implemented CNTBaseN frame:

- CNPCT is accessible in that frame, as a RO register, if the value of CNTACR<n>.RPCT is 1.
- Otherwise, the CNPCT address in that frame is RAZ/WI.

For an implemented CNTELOBaseN frame:

- CNPCT is accessible in that frame if both:
 - CNPCT is accessible in the corresponding CNTBaseN frame.
 - The value of CNTELOACR.EL0PCTEN is 1.
- Otherwise, the CNPCT address in that frame is RAZ/WI.

If the implementation supports 64-bit atomic accesses, then the CNPCT register must be accessible as an atomic 64-bit value.

Configurations

The power domain of CNPCT is IMPLEMENTATION DEFINED.

For more information see *Power and reset domains for the system level implementation of the Generic Timer on page I1-5724*.

Attributes

CNPCT is a 64-bit register.

Field descriptions

The CNPCT bit assignments are:

Bits [63:0]

Physical count value.

Accessing the CNTPCT:

CNTPCT[31:0] can be accessed through its memory-mapped interface:

Component	Frame	Accessibility	Offset
Timer	CNTBaseN	RO	0x000
Timer	CNTELOBaseN	RO	0x000

CNTPCT[63:32] can be accessed through its memory-mapped interface:

Component	Frame	Accessibility	Offset
Timer	CNTBaseN	RO	0x004
Timer	CNTELOBaseN	RO	0x004

13.6.13 CNTSR, Counter Status Register

The CNTSR characteristics are:

Purpose

Provides counter frequency status information.

Usage constraints

This register is accessible as follows:

Default
RO

In a system that supports Secure and Non-secure memory maps the CNTControlBase frame, that includes this register, is implemented only in the Secure memory map.

Configurations

The power domain of CNTSR is IMPLEMENTATION DEFINED.

Some or all fields in this register have defined reset values. These apply only on a reset of the reset domain in which the register is implemented. The register is not affected by a reset of any other reset domain. For more information see *Power and reset domains for the system level implementation of the Generic Timer* on page I1-5724.

Attributes

CNTSR is a 32-bit register.

Field descriptions

The CNTSR bit assignments are:

FCKACK, bits [31:8]

Frequency change acknowledge. Indicates the currently selected entry in the Frequency modes table, see *The Frequency modes table* on page I1-5727.

When this register has an architecturally-defined reset value, this field resets to 0.

Bits [7:2]

Reserved, RES0.

DBGH, bit [1]

Indicates whether the counter is halted because the Halt-on-Debug signal is asserted:

- 0 Counter is not halted.
- 1 Counter is halted.

This field resets to a value that is architecturally UNKNOWN.

Bit [0]

Reserved, RES0.

Accessing the CNTSR:

CNTSR can be accessed through its memory-mapped interface:

Component	Frame	Offset
Timer	CNTControlBase	0x004

13.6.14 CNTTIDR, Counter-timer Timer ID Register

The CNTTIDR characteristics are:

Purpose

Indicates the implemented timers in the memory map, and their features. For each value of N from 0 to 7 it indicates whether:

- Frame CNTBaseN is a view of an implemented timer.
- Frame CNTBaseN has a second view, CNTEL0BaseN.
- Frame CNTBaseN has a virtual timer capability.

Usage constraints

This register is accessible as follows:

Default

RO

In a system that recognizes two Security states this register is accessible by both Secure and Non-secure accesses.

Configurations

The power domain of CNTTIDR is IMPLEMENTATION DEFINED.

For more information see [Power and reset domains for the system level implementation of the Generic Timer on page I1-5724](#).

Attributes

CNTTIDR is a 32-bit register.

Field descriptions

The CNTTIDR bit assignments are:

31	28 27	24 23	20 19	16 15	12 11	8 7	4 3	0
Frame7	Frame6	Frame5	Frame4	Frame3	Frame2	Frame1	Frame0	

Frame<n>, bits [4n+3:4n], for n = 0 to 7

A 4-bit field indicating the features of frame CNTBase<n>.

Bit[3] of the field is RES0.

Bit[2] indicates whether frame CNTBase<n> has a second view, CNTEL0Base<n>. The possible values of this bit are:

Bit[2]	Meaning
--------	---------

0	Frame <n> does not have a second view. CNTEL0Base<n> is RES0.
---	---

1	Frame <n> has a second view, CNTEL0Base<n>.
---	---

If bit[0] is 0, bit[2] is RES0.

Bit[1] indicates whether both:

- Frame CNTBase<n> implements the virtual timer registers CNTV_CVAL, CNTV_TVAL, and CNTV_CTL.
- This CNTCTLBase frame implements the virtual timer offset register CNTVOFF<n>.

The possible values of bit[1] are:

Bit[1]	Meaning
0	Frame <n> does not have virtual capability. The virtual time and offset registers are RES0.
1	Frame <n> has virtual capability. The virtual time and offset registers are implemented.

If bit[0] is 0, bit[1] is RES0.

Bit[0] indicates whether frame CNTBase<n> is implemented. The possible values of this bit are:

Bit[0]	Meaning
0	Frame <n> not implemented. All registers associated with the frame are RES0.
1	Frame <n> is implemented.

Accessing the CNTTIDR:

CNTTIDR can be accessed through its memory-mapped interface:

Component	Frame	Offset
Timer	CNTCTLBase	0x008

13.6.15 CNTV_CTL, Counter-timer Virtual Timer Control

The CNTV_CTL characteristics are:

Purpose

Control register for the virtual timer.

Usage constraints

CNTV_CTL can be implemented in any implemented CNTBaseN frame that has virtual timer capability, and in the corresponding CNTEL0BaseN frame.

[CNTCTLBase status and control fields for the CNTBaseN and CNTEL0BaseN frames on page I1-5733](#) describes the status fields that identify whether a CNTBaseN frame is implemented, and for an implemented frame:

- Whether the CNTBaseN frame has virtual timer capability.
- Whether the corresponding CNTEL0BaseN frame is implemented.
- For an implementation that recognizes two Security states, whether the CNTBaseN frame, and any corresponding CNTEL0BaseN frame, is accessible by Non-secure accesses.

For an implemented CNTBaseN frame that has virtual timer capability:

- CNTV_CTL is accessible in that frame if the value of CNTACR<n>.RWVT is 1.
- Otherwise, the CNTV_CTL address in that frame is RAZ/WI.

For an implemented CNTEL0BaseN frame:

- CNTV_CTL is accessible in that frame if both:
 - CNTV_CTL is accessible in the corresponding CNTBaseN frame.
 - The value of CNTEL0ACR.EL0VTEN is 1.
- Otherwise, the CNTV_CTL address in that frame is RAZ/WI.

Configurations

The power domain of CNTV_CTL is IMPLEMENTATION DEFINED.

On a reset of the reset domain in which an RW instance of this register is implemented, RW fields in the register reset to UNKNOWN values. The register is not affected by a reset of any other reset domain. For more information see [Power and reset domains for the system level implementation of the Generic Timer on page I1-5724](#).

Implementation of this register is OPTIONAL.

Attributes

CNTV_CTL is a 32-bit register.

Field descriptions

The CNTV_CTL bit assignments are:

Bits [31:3]

Reserved, RES0.

ISTATUS, bit [2]

The status of the timer. This bit indicates whether the timer condition is met:

- 0 Timer condition is not met.
- 1 Timer condition is met.

When the value of the ENABLE bit is 1, ISTATUS indicates whether the timer condition is met. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0 then the timer interrupt is asserted.

When the value of the ENABLE bit is 0, the ISTATUS field is UNKNOWN.

For more information see [Operation of the CompareValue views of the timers on page D6-2187](#) and [Operation of the TimerValue views of the timers on page D6-2188](#).

This bit is read-only.

IMASK, bit [1]

Timer interrupt mask bit. Permitted values are:

- 0 Timer interrupt is not masked by the IMASK bit.
- 1 Timer interrupt is masked by the IMASK bit.

For more information, see the description of the ISTATUS bit.

ENABLE, bit [0]

Enables the timer. Permitted values are:

- 0 Timer disabled.
- 1 Timer enabled.

Setting this bit to 0 disables the timer output signal, but the timer value accessible from [CNTV_TVAL](#) continues to count down.

———— **Note** —————

Disabling the output signal might be a power-saving option.

Accessing the CNTV_CTL:

CNTV_CTL can be accessed through its memory-mapped interface:

Component	Frame	Accessibility	Offset
Timer	CNTBaseN	RW	0x03C
Timer	CNTELOBaseN	RW	0x03C

13.6.16 CNTV_CVAL, Counter-timer Virtual Timer CompareValue

The CNTV_CVAL characteristics are:

Purpose

Holds the 64-bit compare value for the virtual timer.

Usage constraints

CNTV_CVAL can be implemented in any implemented CNTBaseN frame that has virtual timer capability, and in the corresponding CNTEL0BaseN frame.

[CNTCTLBase status and control fields for the CNTBaseN and CNTEL0BaseN frames on page I1-5733](#) describes the status fields that identify whether a CNTBaseN frame is implemented, and for an implemented frame:

- Whether the CNTBaseN frame has virtual timer capability.
- Whether the corresponding CNTEL0BaseN frame is implemented.
- For an implementation that recognizes two Security states, whether the CNTBaseN frame, and any corresponding CNTEL0BaseN frame, is accessible by Non-secure accesses.

For an implemented CNTBaseN frame that has virtual timer capability:

- CNTV_CVAL is accessible in that frame if the value of CNTACR<n>.RWVT is 1.
- Otherwise, the CNTV_CVAL address in that frame is RAZ/WI.

For an implemented CNTEL0BaseN frame:

- CNTV_CVAL is accessible in that frame if both:
 - CNTV_CVAL is accessible in the corresponding CNTBaseN frame.
 - The value of CNTEL0ACR.EL0VTEN is 1.
- Otherwise, the CNTV_CVAL address in that frame is RAZ/WI.

If the implementation supports 64-bit atomic accesses, then the CNTV_CVAL register must be accessible as an atomic 64-bit value.

Configurations

The power domain of CNTV_CVAL is IMPLEMENTATION DEFINED.

On a reset of the reset domain in which an RW instance of this register is implemented, RW fields in the register reset to UNKNOWN values. The register is not affected by a reset of any other reset domain. For more information see [Power and reset domains for the system level implementation of the Generic Timer on page I1-5724](#).

Implementation of this register is OPTIONAL.

Attributes

CNTV_CVAL is a 64-bit register.

Field descriptions

The CNTV_CVAL bit assignments are:

CompareValue, bits [63:0]

Holds the virtual timer CompareValue.

When `CNTV_CTL.ENABLE` is 1, the timer condition is met when $(CNTVCT - CompareValue)$ is greater than zero. This means that `CompareValue` acts like a 64-bit upcounter timer. When the timer condition is met:

- `CNTV_CTL.ISTATUS` is set to 1.
- An interrupt is generated if `CNTV_CTL.IMASK` is 0.

When `CNTV_CTL.ENABLE` is 0, the timer condition is not met, but `CNTVCT` continues to count.

Accessing the `CNTV_CVAL`:

`CNTV_CVAL[31:0]` can be accessed through its memory-mapped interface:

Component	Frame	Accessibility	Offset
Timer	CNTBaseN	RW	0x030
Timer	CNTELOBaseN	RW	0x030

`CNTV_CVAL[63:32]` can be accessed through its memory-mapped interface:

Component	Frame	Accessibility	Offset
Timer	CNTBaseN	RW	0x034
Timer	CNTELOBaseN	RW	0x034

13.6.17 CNTV_TVAL, Counter-timer Virtual Timer TimerValue

The CNTV_TVAL characteristics are:

Purpose

Holds the timer value for the virtual timer.

Usage constraints

CNTV_TVAL can be implemented in any implemented CNTBaseN frame that has virtual timer capability, and in the corresponding CNTELOBaseN frame.

[CNTCTLBase status and control fields for the CNTBaseN and CNTELOBaseN frames on page I1-5733](#) describes the status fields that identify whether a CNTBaseN frame is implemented, and for an implemented frame:

- Whether the CNTBaseN frame has virtual timer capability.
- Whether the corresponding CNTELOBaseN frame is implemented.
- For an implementation that recognizes two Security states, whether the CNTBaseN frame, and any corresponding CNTELOBaseN frame, is accessible by Non-secure accesses.

For an implemented CNTBaseN frame that has virtual timer capability:

- CNTV_TVAL is accessible in that frame if the value of CNTACR<n>.RWVT is 1.
- Otherwise, the CNTV_TVAL address in that frame is RAZ/WI.

For an implemented CNTELOBaseN frame:

- CNTV_TVAL is accessible in that frame if both:
 - CNTV_TVAL is accessible in the corresponding CNTBaseN frame.
 - The value of CNTELOACR.EL0VTEN is 1.
- Otherwise, the CNTV_TVAL address in that frame is RAZ/WI.

Configurations

The power domain of CNTV_TVAL is IMPLEMENTATION DEFINED.

On a reset of the reset domain in which an RW instance of this register is implemented, RW fields in the register reset to UNKNOWN values. The register is not affected by a reset of any other reset domain. For more information see [Power and reset domains for the system level implementation of the Generic Timer on page I1-5724](#).

Implementation of this register is OPTIONAL.

Attributes

CNTV_TVAL is a 32-bit register.

Field descriptions

The CNTV_TVAL bit assignments are:

TimerValue, bits [31:0]

The TimerValue view of the virtual timer.

On a read of this register:

- If CNTV_CTL.ENABLE is 0, the value returned is UNKNOWN.
- If CNTV_CTL.ENABLE is 1, the value returned is (CompareValue - CNTVCT).

On a write of this register, CompareValue is set to $(CNTVCT + \text{TimerValue})$, where TimerValue is treated as a signed 32-bit integer.

When `CNTV_CTL.ENABLE` is 1, the timer condition is met when $(CNTVCT - \text{CompareValue})$ is greater than zero. This means that TimerValue acts like a 32-bit downcounter timer. When the timer condition is met:

- `CNTV_CTL.ISTATUS` is set to 1.
- If `CNTV_CTL.IMASK` is 0, an interrupt is generated.

When `CNTV_CTL.ENABLE` is 0, the timer condition is not met, but `CNTVCT` continues to count, so the TimerValue view appears to continue to count down.

Accessing the CNTV_TVAL:

`CNTV_TVAL` can be accessed through its memory-mapped interface:

Component	Frame	Accessibility	Offset
Timer	CNTBaseN	RW	0x038
Timer	CNTEL0BaseN	RW	0x038

13.6.18 CNTVCT, Counter-timer Virtual Count

The CNTVCT characteristics are:

Purpose

Holds the 64-bit virtual count value.

Usage constraints

CNTVCT can be implemented in any implemented CNTBaseN frame, and in the corresponding CNTELOBaseN frame, as a RO register.

CNTCTLBase status and control fields for the CNTBaseN and CNTELOBaseN frames on page I1-5733 describes the status fields that identify whether a CNTBaseN frame is implemented, and for an implemented frame:

- Whether the CNTBaseN frame has virtual timer capability.
- Whether the corresponding CNTELOBaseN frame is implemented.
- For an implementation that recognizes two Security states, whether the CNTBaseN frame, and any corresponding CNTELOBaseN frame, is accessible by Non-secure accesses.

For an implemented CNTBaseN frame:

- CNTVCT is accessible in that frame, as a RO register, if the value of CNTACR<n>.RVCT is 1.
- Otherwise, the CNTVCT address in that frame is RAZ/WI.

For an implemented CNTELOBaseN frame:

- CNTVCT is accessible in that frame if both:
 - CNTVCT is accessible in the corresponding CNTBaseN frame.
 - The value of CNTELOACR.EL0VCTEN is 1.
- Otherwise, the CNTVCT address in that frame is RAZ/WI.

If the implementation supports 64-bit atomic accesses, then the CNTVCT register must be accessible as an atomic 64-bit value.

Configurations

The power domain of CNTVCT is IMPLEMENTATION DEFINED.

For more information see *Power and reset domains for the system level implementation of the Generic Timer on page I1-5724*.

Attributes

CNTVCT is a 64-bit register.

Field descriptions

The CNTVCT bit assignments are:

Bits [63:0]

Virtual count value.

Accessing the CNTVCT:

CNTVCT[31:0] can be accessed through its memory-mapped interface:

Component	Frame	Accessibility	Offset
Timer	CNTBaseN	RO	0x008
Timer	CNTELOBaseN	RO	0x008

CNTVCT[63:32] can be accessed through its memory-mapped interface:

Component	Frame	Accessibility	Offset
Timer	CNTBaseN	RO	0x00C
Timer	CNTELOBaseN	RO	0x00C

13.6.19 CNTVOFF{<n>}, Counter-timer Virtual Offset

The CNTVOFF{<n>} characteristics are:

Purpose

Holds the 64-bit virtual offset.

Usage constraints

In the CNTCTLBase frame a CNTVOFF<n> register must be implemented, as a RW register, for each CNTBaseN frame that has virtual timer capability.

———— Note —————

The value of <n> in an instance of CNTVOFF<n> specifies the value of N for the associated CNTBaseN frame.

In a system that recognizes two Security states, for any CNTVOFF<n> register in the CNTCTLBase frame:

- CNTVOFF<n> is always accessible by Secure accesses.
- CNTNSAR.NS<n> determines whether CNTVOFF<n> is accessible by Non-secure accesses.

The register location of any unimplemented CNTVOFF<n> register in the CNTCTLBase frame is RAZ/WI.

CNTVOFF is implemented, as a RO register, in any implemented CNTBaseN frame that has virtual timer capability.

CNTCTLBase status and control fields for the CNTBaseN and CNTEL0BaseN frames on page I1-5733 describes the status fields that identify whether a CNTBaseN frame is implemented, and for an implemented frame:

- Whether the CNTBaseN frame has virtual timer capability.
- Whether the corresponding CNTEL0BaseN frame is implemented.
- For an implementation that recognizes two Security states, whether the CNTBaseN frame, and any corresponding CNTEL0BaseN frame, is accessible by Non-secure accesses.

For an implemented CNTBaseN frame that has virtual timer capability:

- CNTVOFF is accessible in that frame, as a RO register, if the value of CNTACR<n>.RVOFF is 1.
- Otherwise, the CNTVOFF address in that frame is RAZ/WI.

———— Note —————

CNTVOFF is never visible in any CNTEL0BaseN frame. This means that the CNTVOFF address in any implemented CNTEL0BaseN frame is RAZ/WI.

In an implementation that supports 64-bit atomic accesses, then the CNTVOFF{<n>} register must be accessible as an atomic 64-bit value.

Configurations

The power domain of CNTVOFF is IMPLEMENTATION DEFINED.

On a reset of the reset domain in which an RW instance of this register is implemented, RW fields in the register reset to UNKNOWN values. The register is not affected by a reset of any other reset domain. For more information see *Power and reset domains for the system level implementation of the Generic Timer on page I1-5724*.

Implementation of CNTVOFF<n> is OPTIONAL.

CNTACR<n>.RVOFF enables access to this register for frame CNTBase<n>.

Attributes

CNTVOFF{<n>} is a 64-bit register.

Field descriptions

The CNTVOFF{<n>} bit assignments are:

Bits [63:0]

Virtual offset.

Accessing the CNTVOFF{<n>}:

CNTVOFF{<n>} can be accessed through its memory-mapped interface:

Component	Mnemonic	Frame	Accessibility	Offset
Timer	CNTVOFF<n>[31:0]	CNTCTLBase	RW	0x080 + 8n
Timer	CNTVOFF<n>[64:32]	CNTCTLBase	RW	0x084 + 8n
Timer	CNTVOFF[31:0]	CNTBaseN	RO	0x018
Timer	CNTVOFF[64:32]	CNTBaseN	RO	0x01C

13.6.20 CounterID<n>, Counter ID registers, n = 0 - 11

The CounterID<n> characteristics are:

Purpose

IMPLEMENTATION DEFINED identification registers 0 to 11 for the memory-mapped Generic Timer.

Usage constraints

These registers must be implemented, as RO registers, in every implemented frame of a Generic Timer memory-mapped component.

For the CNTCTLBase frame, in a system that recognizes two Security states these registers are accessible by both Secure and Non-secure accesses.

For the CNTControlBase frame, in a system that supports Secure and Non-secure memory maps the frame is implemented only in the Secure memory map, meaning these registers are implemented only in the Secure memory map.

For the CNTBaseN frames, [CNTCTLBase status and control fields for the CNTBaseN and CNTELOBaseN frames on page I1-5733](#) describes the status fields that identify whether a frame is implemented, and for an implemented frame:

- Whether the CNTBaseN frame has virtual timer capability.
- Whether the corresponding CNTELOBaseN frame is implemented.
- For an implementation that recognizes two Security states, whether the CNTBaseN frame, and any corresponding CNTELOBaseN frame, is accessible by Non-secure accesses.

Configurations

The power domain of CounterID<n> is IMPLEMENTATION DEFINED.

For more information see [Power and reset domains for the system level implementation of the Generic Timer on page I1-5724](#).

These registers are implemented independently in each implemented frame of a Generic Timer memory-mapped component.

If the implementation of the Counter ID registers requires an architecture version, the value for this version of the ARM Generic Timer is version 0.

The Counter ID registers can be implemented as a set of CoreSight ID registers, comprising Peripheral ID Registers and Component ID Registers. An implementation of these registers for the Generic Timer must use a Component class value of 0xF.

Attributes

CounterID<n> is a 32-bit register.

Field descriptions

The CounterID<n> bit assignments are:

IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

Accessing the CounterID<n>:

CounterID<n> can be accessed through its memory-mapped interface:

Component	Frame	Accessibility	Offset
Timer	CNTControlBase	RO	0xFD0 + 4n
Timer	CNTReadBase	RO	0xFD0 + 4n
Timer	CNTBaseN	RO	0xFD0 + 4n
Timer	CNTELOBaseN	RO	0xFD0 + 4n
Timer	CNTCTLBase	RO	0xFD0 + 4n

Part J

Architectural Pseudocode

Chapter J1

ARMv8 Pseudocode

This chapter contains pseudocode that describes many features of the ARMv8 architecture. It contains the following sections:

- *Pseudocode for AArch64 operations on page J1-5860.*
- *Pseudocode for AArch32 operation on page J1-5930.*
- *Shared pseudocode on page J1-6006.*

J1.1 Pseudocode for AArch64 operations

This section holds the pseudocode for execution in AArch64 state. Functions that are listed in this section are identified as `AArch64.FunctionName`. Some of these functions have an equivalent AArch32 function, `AArch32.FunctionName`. This section is organized by functional groups, with the functional groups being indicated by hierarchical path names, for example `aarch64/debug/breakpoint`.

The top-level sections of the AArch64 pseudocode hierarchy are:

- [aarch64/debug](#).
- [aarch64/exceptions](#) on page J1-5869.
- [aarch64/functions](#) on page J1-5887.
- [aarch64/instrs](#) on page J1-5903.
- [aarch64/translation](#) on page J1-5911.

J1.1.1 aarch64/debug

This section includes the following pseudocode functions:

- [aarch64/debug/breakpoint/AArch64.BreakpointMatch](#).
- [aarch64/debug/breakpoint/AArch64.BreakpointValueMatch](#) on page J1-5861.
- [aarch64/debug/breakpoint/AArch64.StateMatch](#) on page J1-5862.
- [aarch64/debug/enables/AArch64.GenerateDebugExceptions](#) on page J1-5863.
- [aarch64/debug/enables/AArch64.GenerateDebugExceptionsFrom](#) on page J1-5863.
- [aarch64/debug/pmu/AArch64.CheckForPMUOverflow](#) on page J1-5864.
- [aarch64/debug/pmu/AArch64.CountEvents](#) on page J1-5864.
- [aarch64/debug/statisticalprofiling/CheckProfilingBufferAccess](#) on page J1-5865.
- [aarch64/debug/statisticalprofiling/CheckStatisticalProfilingAccess](#) on page J1-5865.
- [aarch64/debug/statisticalprofiling/CollectContextIDR1](#) on page J1-5866.
- [aarch64/debug/statisticalprofiling/CollectContextIDR2](#) on page J1-5866.
- [aarch64/debug/statisticalprofiling/CollectPhysicalAddress](#) on page J1-5866.
- [aarch64/debug/statisticalprofiling/CollectRecord](#) on page J1-5866.
- [aarch64/debug/statisticalprofiling/CollectTimeStamp](#) on page J1-5867.
- [aarch64/debug/statisticalprofiling/OpType](#) on page J1-5867.

J1.2 Pseudocode for AArch32 operation

This section holds the pseudocode for execution in AArch32 state. Functions that are listed in this section are identified as `AArch32.FunctionName`. Some of these functions have an equivalent AArch64 function, `AArch64.FunctionName`. This section is organized by functional groups, with the functional groups being indicated by hierarchical path names, for example `aarch32/debug/breakpoint`.

———— Note ————

Many AArch32 pseudocode functions have not been updated to show the constraints on the ARMv7 UNPREDICTABLE behaviors that are described in [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#). Where AArch32 pseudocode shows something to be UNPREDICTABLE, check [Appendix K1](#) for possible constraints on the permitted behavior.

The top-level sections of the AArch32 pseudocode hierarchy are:

- [aarch32/debug](#).
- [aarch32/exceptions](#) on page J1-5938.
- [aarch32/functions](#) on page J1-5956.
- [aarch32/translation](#) on page J1-5985.

J1.2.1 aarch32/debug

This section includes the following pseudocode functions:

- [aarch32/debug/VCRMatch/AArch32.VCRMatch](#).
- [aarch32/debug/authentication/AArch32.SelfHostedSecurePrivilegedInvasiveDebugEnabled](#) on page J1-5931.
- [aarch32/debug/breakpoint/AArch32.BreakpointMatch](#) on page J1-5931.
- [aarch32/debug/breakpoint/AArch32.BreakpointValueMatch](#) on page J1-5932.
- [aarch32/debug/breakpoint/AArch32.StateMatch](#) on page J1-5933.
- [aarch32/debug/enables/AArch32.GenerateDebugExceptions](#) on page J1-5934.
- [aarch32/debug/enables/AArch32.GenerateDebugExceptionsFrom](#) on page J1-5934.
- [aarch32/debug/pmu/AArch32.CheckForPMUOverflow](#) on page J1-5935.
- [aarch32/debug/pmu/AArch32.CountEvents](#) on page J1-5935.
- [aarch32/debug/takeexceptiondbg/AArch32.EnterHypModeInDebugState](#) on page J1-5936.
- [aarch32/debug/takeexceptiondbg/AArch32.EnterModeInDebugState](#) on page J1-5936.
- [aarch32/debug/takeexceptiondbg/AArch32.EnterMonitorModeInDebugState](#) on page J1-5937.
- [aarch32/debug/watchpoint/AArch32.WatchpointByteMatch](#) on page J1-5937.
- [aarch32/debug/watchpoint/AArch32.WatchpointMatch](#) on page J1-5938.

J1.3 Shared pseudocode

This section holds the pseudocode that is common to execution in AArch64 state and in AArch32 state. Functions listed in this section are identified only by a `FunctionName`, without an `AArch64.` or `AArch32.` prefix. This section is organized by functional groups, with the functional groups being indicated by hierarchical path names, for example `shared/debug/DebugTarget`.

———— Note ————

Currently, the following pseudocode functions in this group reference C program functions, that are not linked from the pseudocode, to describe their operation:

`UnsignedRecipEstimate()`

Calls the C function `recip_estimate()`. This function is defined in *Floating-point reciprocal estimate and step* on page E1-2749.

`UnsignedRSqrtEstimate()`

Calls the C function `recip_sqrt_estimate()`. This function is defined in *Floating-point reciprocal square root estimate and step* on page E1-2750.

The top-level sections of the shared pseudocode hierarchy are:

- [shared/debug](#).
- [shared/exceptions](#) on page J1-6024.
- [shared/functions](#) on page J1-6026.
- [shared/translation](#) on page J1-6086.

J1.3.1 shared/debug

This section includes the following pseudocode functions:

- [shared/debug/ClearStickyErrors/ClearStickyErrors](#) on page J1-6007.
- [shared/debug/DebugTarget/DebugTarget](#) on page J1-6007.
- [shared/debug/DebugTarget/DebugTargetFrom](#) on page J1-6008.
- [shared/debug/DoubleLockStatus/DoubleLockStatus](#) on page J1-6008.

Architectural Constraints on UNPREDICTABLE behaviors

This chapter describes the architectural constraints on UNPREDICTABLE behaviors in the ARMv8 architecture. It contains the following sections:

- [AArch32 CONSTRAINED UNPREDICTABLE behaviors on page K1-6096.](#)
- [AArch64 CONSTRAINED UNPREDICTABLE behaviors on page K1-6119.](#)

K1.1 AArch32 CONSTRAINED UNPREDICTABLE behaviors

ARMv8 defines architecturally-required constraints on many behaviors that are UNPREDICTABLE in ARMv7. The following sections define those constraints:

- *Overview of the constraints on ARMv7 UNPREDICTABLE behaviors on page K1-6097.*
- *Using R13 on page K1-6097.*
- *Using R15 on page K1-6097.*

K1.1.1 Overview of the constraints on ARMv7 UNPREDICTABLE behaviors

The term UNPREDICTABLE describes a number of cases where the architecture has a feature that software must not use. For execution in AArch32 state, where previous versions of the architecture define behavior as UNPREDICTABLE, the ARMv8-A architecture specifies a narrow range of permitted behaviors. This range is the range of CONSTRAINED UNPREDICTABLE behavior. All implementations that are compliant with the architecture must follow the CONSTRAINED UNPREDICTABLE behavior.

———— **Note** —————

Software designed to be compatible with the ARMv8-A architecture must not rely on these CONSTRAINED UNPREDICTABLE cases.

K1.1.2 Using R13

In prior versions of the architecture, the use of R13 as a named register specifier was described as UNPREDICTABLE in the pseudocode. In the ARMv8-A architecture, the use of R13 as a named register specifier is not UNPREDICTABLE, unless this is specifically stated, and R13 can be used in the regular form. Bits[1:0] of R13 are not treated as RES0, but can hold any values programmed into them.

K1.1.3 Using R15

All uses of R15 as a named register specifier for a source register that are described as CONSTRAINED UNPREDICTABLE in the pseudocode or in other places in this Manual must do one of the following:

- Cause the instruction to be treated as UNDEFINED.
- Cause the instruction to execute as a NOP.
- Read or return an UNKNOWN value for the source register specified as R15.

All uses of R15 as a named register specifier for a destination register that are described as CONSTRAINED UNPREDICTABLE in the pseudocode or in other places in this reference manual must do one of the following:

- Cause the instruction to be treated as UNDEFINED.
- Cause the instruction to execute as a NOP.
- Ignore the write.
- Branch to an UNKNOWN location in either A32 or T32 state.

The choice between these behaviors might in some implementations vary from instruction to instruction, or between different instances of the same instruction.

Instructions that are CONSTRAINED UNPREDICTABLE when the base register is R15 and the instruction specifies a writeback of the base register, are treated as having R15 as both a source register and a destination register.

For instructions that have two destination registers, for example LDRD, MRRC, and many of the multiply instructions, if Rt, Rt2, RdLo, or RdHi is R15, then the other destination register of the pair is UNKNOWN, if the CONSTRAINED UNPREDICTABLE behavior for the write to R15 is either to ignore the write or to branch to an UNKNOWN location.

For instructions that affect any or all of **PSTATE**.{N, Z, C, V}, **PSTATE**.Q, and **PSTATE**.GE when the register specifier is not R15, any flags affected by an instruction that is CONSTRAINED UNPREDICTABLE when the register specifier is R15 become UNKNOWN,

In addition, for MRC instructions that use R15 as the destination register descriptor, and therefore target APSR_nzcv where these are described as being CONSTRAINED UNPREDICTABLE, **PSTATE**.{N, Z, C, V} becomes UNKNOWN.

K1.1.4 Branching into an IT block

Branching into an IT block leads to CONSTRAINED UNPREDICTABLE behavior. Execution starts from the address determined by the branch, but each instruction in the IT block is:

- Executed as if it were not in an IT block. This means that it is executed unconditionally.
- Executed as if it had passed its [Condition code check](#) within an IT block.
- Executed as a NOP. That is, it behaves as if it had failed the [Condition code check](#).

K1.1.5 Branching to an unaligned PC

In A32 state, when branching to an address that is not word aligned and is defined to be CONSTRAINED UNPREDICTABLE, one of the following behaviors must occur:

- The unaligned location is forced to be aligned.
 - The unaligned address generates an exception on the first instruction using the unaligned PC value. If that instruction is executed at EL0 and either of the following applies, the exception is taken to EL2:
 - EL2 is using AArch32 and the value of [HCR.TGE](#) is 1
 - EL2 is using AArch64 and the value of [HCR_EL2.TGE](#) is 1.If the instruction is executed at EL0 when the applicable TGE bit is 0 the exception is taken to EL1. If the instruction is executed at an Exception level that is higher than EL0 the exception is taken to the Exception level at which the instruction was executed.
- In all cases, the exception is generated only if the first instruction using the unaligned PC value is architecturally executed.

If the exception that results from a branch to an unaligned PC value:

- Is taken to an Exception level that is using AArch64, it is reported as a PC alignment fault exception, see [Exception from an Illegal Execution state, PC alignment fault, or SP alignment fault on page D1-1808](#).
- Is taken to an Exception level that is using AArch32, it is reported as a Prefetch Abort exception, see [Prefetch Abort exception reporting a PC alignment fault exception on page G1-4385](#).

———— **Note** —————

Because bit[0] is used for interworking, it is impossible to specify a branch to A32 state when the bottom bit of the target address is 1. Therefore the bottom bit of [IFAR](#), [HIFAR](#), or [FAR_ELx](#) is 0 for all these cases.

K1.1.6 Loads and Stores to unaligned locations

Some unaligned loads and stores in the ARMv7 architecture are described as UNPREDICTABLE. These are defined in the ARMv8-A architecture to do one of the following:

- Take an alignment fault.
- Perform the specified load or store to the unaligned memory location.

K1.1.7 CONSTRAINED UNPREDICTABLE behavior associated with IT instructions and PSTATE.IT

A number of instructions in the architecture are described as being CONSTRAINED UNPREDICTABLE either:

- Anywhere within an IT block.
- As an instruction within an IT block, other than the last instruction within an IT block.

Unless otherwise stated in this manual, when these instructions are committed for execution, one of the following occurs:

- An UNDEFINED exception results.
- The instructions are executed as if they had passed the [Condition code check](#).
- The instructions execute as NOPs. This means that they behave as if they had failed the [Condition code check](#).

The behavior might in some implementations vary from instruction to instruction, or between different instances of the same instruction.

Many instructions that are CONSTRAINED UNPREDICTABLE in an IT block are branch instructions or other non-sequential instructions that change the PC. Where these instructions are not treated as UNDEFINED within an IT block, the remaining iterations of the PSTATE.IT state machine must be treated in one of the following ways:

- PSTATE.IT is cleared to 0.
- PSTATE.IT advances for either a sequential or a nonsequential change of the PC in the same way as it does for instructions that are not CONSTRAINED UNPREDICTABLE that cause a sequential change of the PC.

———— **Note** —————

This does not apply to an instruction that is the last instruction in an IT block.

The instructions addressed by the updated PC must do one of the following:

- Execute as if they had passed the [Condition code check](#) for the remaining iterations of the PSTATE.IT state machine.
- Execute as NOPs. That is, they behave as if they had failed the [Condition code check](#) for the remaining iterations of the PSTATE.IT state machine.
- Execute as if they were unconditional, or, if the instructions are part of another IT block, in accordance with the behavior described in [Branching into an IT block on page K1-6098](#).

The behavior might in some implementations vary from instruction to instruction, or between different instances of the same instruction.

For exception returns or Debug state exits that cause PSTATE.IT to be set to a reserved value in T32 state or that return to A32 state with a nonzero value in PSTATE.IT, the PSTATE.IT bits are forced to '00000000'. The reserved values are:

```
PSTATE.IT[7:4] != '0000' && PSTATE.IT[3:0] = '0000'  
PSTATE.IT[2:0] != '000' when SCTLR/SCTLR_EL1.ITD == '1'
```

Exception returns or Debug state exits that set PSTATE.IT to a non-reserved value in T32 state can occur when the flow of execution returns to a point:

- Outside an IT block, but with the PSTATE.IT bits set to a value other than '00000000'.
- Inside an IT block, but with a different value of the PSTATE.IT bits than if the IT block had been executed without an exception return or Debug state exit.

In this case the instructions at the target of the exception return or Debug state exit must do one of the following:

- Execute as if they passed the [Condition code check](#) for the remaining iterations of the PSTATE.IT state machine.
- Execute as NOPs. That is, they behave as if they failed the [Condition code check](#) for the remaining iterations of the PSTATE.IT state machine.
- Execute as if they were unconditional, or as if the instruction were part of another IT block, in accordance with the behavior in [Branching into an IT block on page K1-6098](#).

The remaining iterations of the PSTATE.IT state machine must behave in one of the following ways:

- The PSTATE.IT state machine advances as if it were in an IT block.
- The PSTATE.IT bits are ignored.
- The PSTATE.IT bits are forced to '00000000'.

K1.1.8 Unallocated System register access instructions

In ARMv8-A, accesses to unallocated System register encodings are UNDEFINED.

This includes:

- Reads using encodings that are defined as WO.
- Writes using encodings that are defined as RO.
- MCR or MRC accesses to using a set of {coproc, CRn, opc1, CRm, opc2} values that the ARMv7 architecture defined as UNPREDICTABLE.
- Accesses to System registers in the (coproc==0b111x) encoding space that the ARMv7 architecture defined as UNPREDICTABLE when particular functionality was not implemented, when an ARMv8 implementation does not include the Exception level that provides that functionality.

K1.1.9 SBZ or SBO fields T32 and A32 in instructions

Many of the A32 and T32 instructions have (0) or (1) in the instruction decode to indicate *should-be-zero*, SBZ, or *should-be-one*, SBO. If the instruction bit pattern of an instruction is executed with these fields not having the *should be* values, one of the following must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction operates as if the bit had the *should-be* value.
- Any destination registers of the instruction become UNKNOWN.

The exceptions to this rule are:

- [LDM, LDMIA, LDMFD](#) on page F5-3144.
- [LDMDB, LDMEA](#) on page F5-3154.
- [LDR \(literal\)](#) on page F5-3163.
- [LDRB \(literal\)](#) on page F5-3172.
- [LDRD \(immediate\)](#) on page F5-3180.
- [LDRD \(register\)](#) on page F5-3186.
- [LDRD \(literal\)](#) on page F5-3183.
- [LDRH \(literal\)](#) on page F5-3200.
- [LDRSB \(literal\)](#) on page F5-3211.
- [LDRSH \(literal\)](#) on page F5-3222.
- [POP](#) on page F5-3325.
- [PUSH](#) on page F5-3331.
- [SDIV](#) on page F5-3407.
- [STM, STMIA, STMEA](#) on page F5-3495.
- [STMDB, STMFD](#) on page F5-3503.
- [UDIV](#) on page F5-3610.

K1.1.10 UNPREDICTABLE cases in immediate constants in T32 data-processing instructions

The description of immediate constants in T32 data processing [Modified immediate constants in T32 instructions](#) on page F2-2863 include constant values that were UNPREDICTABLE in ARMv7. [Instruction encodings](#) on page F2-2844 describes 32-bit T32 instructions as {hw1, hw2}, where hw1 is the left-hand halfword in the 32-bit encoding diagram for the instruction. The UNPREDICTABLE cases are those where both:

- hw2[7:0] == 0b0000000.
- hw1[10] == 0 and either:
 - hw2[14:12] == 0b001.
 - hw2[14:12] == 0b010.
 - hw2[14:12] == 0b011.

In ARMv8 the CONSTRAINED UNPREDICTABLE behavior is that these encodings produce the value `0b0000000`.

K1.1.11 UNPREDICTABLE cases in immediate constants in Advanced SIMD instructions

The description of immediate constants in *Modified immediate constants in T32 and A32 Advanced SIMD instructions* on page F2-2865 include constant values that were UNPREDICTABLE in ARMv7. The UNPREDICTABLE cases are those where:

- The bits that the encoding diagram shows as `abcd` are all 0.
In the A32 encoding these are bits[24, 18:6, 3:0]. In the T32 encoding they are bits {hw1[12, 2:0], hw2[3:0]}.
- The bits that the encoding diagram shows as `cmode[3:1]` are one of {0b001, 0b010, 0b011, 0b101, 0b110}.
In the A32 encoding these are bits[11:9]. In the T32 encoding they are bits hw2[11:9].

In ARMv8 the CONSTRAINED UNPREDICTABLE behavior is that these encodings produce an immediate constant value of zero.

K1.1.12 CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values

The ARM architecture allows copies of control values or data values to be cached in a cache or TLB. This can lead to CONSTRAINED UNPREDICTABLE behavior if the cache or TLB has not been correctly invalidated following a change of the control or data values.

Unless explicitly stated otherwise, the behavior of the PE is consistent with one of:

- The old data or control value.
- The new data or control value.
- An amalgamation of the old and new data or control values.

In an implementation that includes ARMv8.2-TTCNP, this CONSTRAINED UNPREDICTABLE case can arise from misprogramming when setting `TTBR.CnP` to 1, as identified in the descriptions of the `TTBR.CnP` field. In this case, for a particular `TTBR`, the behavior of the PE is consistent with one of:

- The value of the translation table entry pointed to by that `TTBR` on one of the PEs within the Inner Shareable domain for which both the value of `TTBR.CnP` is 1 and the other conditions for sharing translation table entries pointed to by that `TTBR` are met.
- An amalgamation of the values of the translation table entries pointed to by that `TTBR` on two or more of the PEs within the Inner Shareable domain for which both the value of `TTBR.CnP` is 1 and the other conditions for sharing translation table entries pointed to by that `TTBR` are met.

————— Note —————

If the effective control or data value that determines the behavior of the PE results from the amalgamation of two or more values then that effective value must not generate a privilege violation. So, for example:

- Where the CONSTRAINED UNPREDICTABLE behavior occurs because inadequate invalidation of the TLB causes multiple hits in the TLB, the failure to invalidate the TLB by software executing at a given Exception level and Security state must not make it possible to access regions of memory with permissions or attributes that could not be accessed at that Exception level and Security state.
- Where the CONSTRAINED UNPREDICTABLE behavior occurs because of a programming error, on one or more PEs in the Inner Shareable domain, when using a `TTBR.CnP` value of 1 to share translation table entries, the misprogramming must not make it possible to access regions of memory with permissions or attributes that could not be accessed at the Exception level of that `TTBR` and the Security state corresponding to the translation table entries being shared.

Alternatively to this CONSTRAINED UNPREDICTABLE behavior, an implementation detecting multiple hits within a TLB might generate an exception, reporting the exception using the TLB Conflict fault code, see *TLB conflict aborts* on page G4-4630.

The choice between the behaviors might, in some implementations, vary for each use of a control or data value.

K1.1.13 CONSTRAINED UNPREDICTABLE behavior due to inadequate context synchronization

The ARM architecture requires that changes to System registers must be synchronized before they take effect. This can lead to CONSTRAINED UNPREDICTABLE behavior if the synchronization has not been performed.

In these cases, the behavior of the PE is consistent with the unsynchronized control value being either the old value or the new value.

Where multiple control values are updated but not yet synchronized, each control value might independently be the old value or the new value.

In addition, where the unsynchronized control value applies to different areas of functionality, or what an implementation has constructed as different areas of functionality, those areas might independently treat the control value as being either the old value or the new value.

The choice between these behaviors might, in some implementations, vary for each use of a control value.

K1.1.14 Translation Table Base Address alignment

A misaligned Translation Table Base Address can occur if:

- The VMSAv8-32 Short-descriptor translation table format is enabled and `TTBR0[13-N:7]`, which is defined to be `RES0`, contains one or more nonzero values.
- The VMSAv8-32 Long-descriptor translation table format is enabled, and `TTBR0[x-1:3]`, `TTBR1[x-1:3]`, `HTTBR[x-1:3]`, or `VTTBR[x-1:3]`, which are defined to be `RES0`, contain one or more nonzero values.

In the event of a misaligned Translation Table Base Address, one of the following behaviors must occur:

- The field that is defined to be `RES0` is treated as if all bits were zero:
 - The value that is read back might be the value written or it might be zero.
- The calculation of an address for a translation table walk using that register might be corrupted in those bits that are nonzero.

K1.1.15 Handling of System register control fields for Advanced SIMD and floating-point operation

For historical reasons described in *Background to the System register interface on page G1-4410*, each of the `CPACR`, `HCPTR`, and `NSACR` has a pair of control fields that were defined to have identical functionality for controlling Advanced SIMD and floating-point operation. These fields are:

- `CPACR`.{cp10, cp11}.
- `HCPTR`.{TCP10, TCP11}.
- `NSACR`.{cp10, cp11}.

The architecture requires that both fields in one of these pairs are programmed to the same value. If this is not done, then the CONSTRAINED UNPREDICTABLE behavior is that behavior is the same as if the cp11, or TCP11, control field was equal to the cp10, or TCP10, field in all respects other than the value read back by a direct read of the register. After a register write that writes different values to the two fields of a pair, a direct read of the register might return an UNKNOWN value for the cp11 or TCP11 field.

———— **Note** —————

This means that, when different values are written to the {cp10, cp11} fields in a single register, the architecture permits but does not require that a read of that register returns the value written to the cp11 field.

CONSTRAINED UNPREDICTABLE CPACR and NSACR settings

If **CPACR**.cp<n> contains the encoding '10', then one of the following behaviors must occur:

- The encoding maps onto any of the allocated values, but otherwise does not cause UNPREDICTABLE behavior.
- The encoding causes effects that could be achieved by a combination of more than one of the allocated encodings.

———— Note —————

In ARMv7, **CPACR** had a D32DIS bit, and **NSACR** had an NSD32DIS bit. There is no **CPACR**.D32DIS or **NSACR**.NSD32DIS in ARMv8-A, and the corresponding bits in the two registers are RES0.

K1.1.16 The Performance Monitors Extension

The following subsections describe CONSTRAINED UNPREDICTABLE behaviors when accessing the Performance Monitors Extension in AArch32 state:

- *CONSTRAINED UNPREDICTABLE accesses to **PMXEVTYPER** or **PMXVCNTR**.*
- *CONSTRAINED UNPREDICTABLE accesses to **PMEVCNTR**<n> and **PMEVTYPER**<n> on page K1-6104.*
- *CONSTRAINED UNPREDICTABLE behavior caused by **HDCR**.HPMN on page K1-6104.*

CONSTRAINED UNPREDICTABLE accesses to **PMXEVTYPER** or **PMXVCNTR**

The following cases can cause CONSTRAINED UNPREDICTABLE behavior:

- If **PMSELR**.SEL is not equal to 31, and **PMSELR**.SEL is greater than or equal to **PMCR**.N, and the PE is executing in Secure state or in Non-secure Hyp mode.
- If **PMSELR**.SEL is not 31, and **PMSELR**.SEL is greater than or equal to **HDCR**.HPMN, and the PE is executing in a Non-secure mode other than Hyp mode.

In these UNPREDICTABLE cases, one of the following behaviors must occur:

- Accesses to **PMXEVTYPER** or **PMXVCNTR** from that mode are UNDEFINED.
- Accesses to **PMXEVTYPER** or **PMXVCNTR** from that mode behave as RAZ/WI.
- Accesses to **PMXEVTYPER** or **PMXVCNTR** from that mode execute as NOPs.
- Accesses to **PMXEVTYPER** or **PMXVCNTR** from that mode behave as if **PMSELR**.SEL contains an UNKNOWN value that is less than the number of counters accessible at the current Exception level and Security state.
- Accesses to **PMXEVTYPER** or **PMXVCNTR** behave as if **PMSELR**.SEL is 31.
- In Non-secure state, for an access to **PMXEVTYPER** or **PMXVCNTR** from PL1 or a permitted access from PL0, if the counter is implemented but not accessible at the current Exception level, the register access is trapped to EL2. Accesses from PL0 are permitted when:
 - EL1 is using AArch32 and the value of **PMUSERENR**.EN is 1.
 - EL1 is using AArch64 and the value of **PMUSERENR**._EL0.EN is 1.

If **PMSELR**.SEL is equal to 31, then one of the following behaviors must occur:

- Accesses to **PMXVCNTR** are UNDEFINED.
- Accesses to **PMXVCNTR** behave as RAZ/WI.
- Accesses to **PMXVCNTR** execute as NOPs.
- Accesses to **PMXVCNTR** behave as if **PMSELR**.SEL contains an UNKNOWN value that is less than the number of counters accessible at the current Exception level and Security state.

- In Non-secure state, for an access to [PMXEVNTR](#) from PL1 or a permitted access from PL0, if the counter is implemented but not accessible at the current Exception level, the register access is trapped to EL2. Accesses from PL0 are permitted when:
 - EL1 is using AArch32 and the value of [PMUSERENR.EN](#) is 1.
 - EL1 is using AArch64 and the value of [PMUSERENR_EL0.EN](#) is 1.

———— **Note** —————

In an implementation that includes EL2, in Non-secure state at PL0 and PL1, [HDCR.HPMN](#), or [MDCR_EL2.HPMN](#), identifies the number of accessible counters. Otherwise, the number of accessible counters is the number of implemented counters.

CONSTRAINED UNPREDICTABLE accesses to [PMEVCNTR<n>](#) and [PMEVTYPER<n>](#)

If [<n>](#) is greater than the number of counters available in the current Exception level and state, reads and writes of [PMEVCNTR<n>](#) and [PMEVTYPER<n>](#) are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a NOP.
- In Non-secure state, for an access to [PMEVCNTR<n>](#) or [PMEVTYPER<n>](#) from PL1 or a permitted access from PL0, if the counter is implemented but not accessible at the current Exception level, the register access is trapped to EL2. Accesses from PL0 are permitted when:
 - EL1 is using AArch32 and the value of [PMUSERENR.EN](#) is 1.
 - EL1 is using AArch64 and the value of [PMUSERENR_EL0.EN](#) is 1.

———— **Note** —————

In an implementation that includes EL2, in Non-secure state at PL0 and PL1, [HDCR.HPMN](#), or [MDCR_EL2.HPMN](#), identifies the number of accessible counters. Otherwise, the number of accessible counters is the number of implemented counters.

CONSTRAINED UNPREDICTABLE behavior caused by [HDCR.HPMN](#)

If [HDCR.HPMN](#) is set to 0 or to a value greater than [PMCR.N](#), then the CONSTRAINED UNPREDICTABLE behavior is:

- The value returned by a direct read of [HDCR.HPMN](#) is UNKNOWN.
- Either:
 - An UNKNOWN number of counters are reserved for EL2 use. That is, the PE behaves as if [HDCR.HPMN](#) is set to an UNKNOWN non-zero value less than [PMCR.N](#).
 - All counters are reserved for EL2 use, meaning no counters are accessible from Non-secure EL1 and Non-secure EL0.

K1.1.17 Syndrome register handling for CONSTRAINED UNPREDICTABLE instructions treated as UNDEFINED

When a CONSTRAINED UNPREDICTABLE instruction is treated as UNDEFINED, this generates an exception:

- If this exception is taken to an Exception level that is using AArch64 then [ESR_ELx](#) is UNKNOWN.
- If this exception is taken to EL2 and EL2 is using AArch32, then the [HSR](#) is UNKNOWN.

———— **Note** —————

The value written to ESR or HSR must be consistent with a value that could be created as the result of an exception from the same Exception level that generated the exception, but resulted from a situation that is not CONSTRAINED UNPREDICTABLE at that Exception level. This is to avoid a possible privilege violation.

K1.1.18 Out of range virtual address

If the PE executes an instruction for which the instruction address, size, and alignment mean it contains the bytes 0xFFFF FFFF and 0x0000 0000, then the bytes that wrap around and appear to be from 0x0000 0000 onwards come from an UNKNOWN address.

If the PE executes a load or store instruction for which the computed address, total access size, and alignment mean it accesses bytes 0xFFFF FFFF and 0x0000 0000, then the bytes that wrap around and appear to be from 0x0000 0000 onwards come from an UNKNOWN address.

K1.1.19 Instruction fetches from Device memory

Instruction fetches from Device memory are CONSTRAINED UNPREDICTABLE.

If a location in memory has the Device attribute and is not marked as execute-never, then an implementation might perform speculative instruction accesses to this memory location when address translation is enabled.

If a branch causes the program counter to point to a location in memory with the Device attribute that is not marked as execute-never for the current Exception level for instruction fetches, then an implementation must perform one of the following behaviors:

- It treats the instruction fetch as if it were to a memory location with the Normal, Non-cacheable attribute.
- It generates a Permission fault.

K1.1.20 Multi-access instructions that load the PC from Device memory

Multi-access instructions that load the PC from Device memory when address translation is enabled are UNPREDICTABLE in AArch32 state. In the ARMv8-A architecture in AArch32 state an implementation must perform one of the following behaviors:

- It loads the PC from the memory location as if the memory location had the Normal Non-cacheable attribute.
- It generates a permission fault.

K1.1.21 Programming CSSELR.Level for a cache level that is not implemented

If CSSELR.Level is programmed to a cache level that is not implemented, then a read of CSSELR returns an UNKNOWN value in CSSELR.Level.

If the CSSELR.Level is programmed to a cache level that is not implemented, then on a read of CCSIDR an implementation must perform one of the following behaviors:

- The CCSIDR read executes as a NOP.
- The CCSIDR read is UNDEFINED.
- The CCSIDR read returns an UNKNOWN value.

K1.1.22 Crossing a page boundary with different memory types or Shareability attributes

A memory access from a load or store instruction that crosses a page boundary to a memory location that has a different memory type or Shareability attribute results in CONSTRAINED UNPREDICTABLE behavior. In this case, the implementation must perform one of the following behaviors:

- All memory accesses generated by the instruction use the memory type and Shareability attributes associated with the first address accessed by the instruction.
- All memory accesses generated by the instruction use the memory type and Shareability attributes associated with the last address accessed by the instruction.
- Each memory access generated by the instruction uses the memory type and Shareability attribute associated with its own address.

- The instruction generates an alignment fault caused by the memory type.
For the Non-secure PL1&0 translation regime:
 - If the stage 1 translation causes the mismatch then the resulting exception is taken to PL1.
 - If the stage 2 translation causes the mismatch then the resulting exception is taken to PL2.
 - If both stages of translation cause the mismatch then the resulting exception can be taken to either PL1 or PL2.
- The instruction executes as a NOP.

K1.1.23 Crossing a 4KB boundary with a Device access

A memory access from a load or store instruction to Device memory that crosses a 4KB boundary results in CONSTRAINED UNPREDICTABLE behavior. In this case, the implementation must perform one of the following behaviors:

- All memory accesses generated by the instruction are performed as if the presence of the boundary had no effect on the memory accesses.
- All memory accesses generated by the instruction are performed as if the presence of the boundary had no effect on the memory accesses, except that there is no guarantee of ordering between memory accesses.
- The instruction generates an Alignment fault caused by the memory type.
For the Non-secure PL1&0 translation regime:
 - If the stage 1 translation causes the boundary to be crossed then the resulting exception is taken to PL1.
 - If the stage 2 translation causes the boundary to be crossed then the resulting exception is taken to PL2.
 - If both stages of translation cause the boundary to be crossed then the resulting exception can be taken to either PL1 or PL2.
- The instruction executes as a NOP.

———— **Note** —————

The boundary referred to is between two Device memory regions that are both of 4KB and aligned to 4KB.

K1.1.24 UNPREDICTABLE behaviors with Load-Exclusive/Store-Exclusive pairs

[Load-Exclusive and Store-Exclusive instruction usage restrictions on page E2-2802](#) defines a Load-Exclusive/Store-Exclusive pair, and identifies various CONSTRAINED UNPREDICTABLE behaviors associated with using Load-Exclusive/Store-Exclusive pairs. These cases were UNPREDICTABLE in ARMv7. In summary, these cases are:

- The target virtual address of a StoreExc1 instruction is different from the virtual address of the preceding LoadExc1 instruction in the same thread of execution.
- The transaction size of a StoreExc1 instruction is different from the transaction size of the preceding LoadExc1 instruction in the same thread of execution.
- The memory attributes for a StoreExc1 instruction are different from the memory attributes for the preceding LoadExc1 instruction in the same thread of execution, either:
 - Because the translation of the accessed address changes between the LoadExc1 instruction and the StoreExc1 instruction.
 - Because the LoadExc1 instruction and the StoreExc1 instruction use different virtual addresses, with different attributes, that point to the same physical address.

In addition, the effect of a data or unified cache invalidate, clean, or clean and invalidate instruction on a local or global Exclusives monitor that is in the Exclusive Access state is CONSTRAINED UNPREDICTABLE.

See the descriptions in [Load-Exclusive and Store-Exclusive instruction usage restrictions on page E2-2802](#) for the permitted behavior in each of these cases, and any constraints that might apply to whether the case is CONSTRAINED UNPREDICTABLE.

———— **Note** ————

Additional CONSTRAINED UNPREDICTABLE cases can apply to Load-Exclusive and Store-Exclusive instructions, see [CONSTRAINED UNPREDICTABLE behavior for A32 and T32 system instructions in the base instruction set on page K1-6108](#).

K1.1.25 CONSTRAINED UNPREDICTABLE behavior for A32 and T32 instruction encodings

The A32 and T32 instruction sets include encodings that result in CONSTRAINED UNPREDICTABLE behavior when they are decoded.

CONSTRAINED UNPREDICTABLE behavior of CRC32 instruction encodings

In the A32 and T32 instruction sets, there are encodings of the [CRC32](#) and [CRC32C](#) instructions that result in CONSTRAINED UNPREDICTABLE behavior. These encodings are listed in the following places in the A32 and T32 instruction sets:

- [Cyclic Redundancy Check on page F4-2952](#) for the A32 instruction set, with $sz = 11$.
- [Data-processing \(two source registers\) on page F3-2937](#) for the T32 instruction set, with $op1 = 10x$ and $op2 = 11$.

The CONSTRAINED UNPREDICTABLE behavior for these encodings is described in [CRC32 on page F5-3094](#) and [CRC32C on page F5-3097](#).

CONSTRAINED UNPREDICTABLE behavior of other A32 instruction encodings

In the A32 instruction set, there are encodings that result in CONSTRAINED UNPREDICTABLE behavior. These encodings are listed in:

- [Miscellaneous on page F4-2984](#).
- [Memory hints and barriers on page F4-2995](#).
- [Barriers on page F4-2996](#).

The CONSTRAINED UNPREDICTABLE behavior is that an implementation must treat the encodings in one of the following ways:

- The instruction encoding is UNDEFINED.
- The instruction encoding executes as NOP.

K1.1.26 Out of range values of the Set/Way/Index fields in cache maintenance instructions

In the cache maintenance by set/way instructions [DCCISW](#), [DCCSW](#), and [DCISW](#), if any set/way/index argument is larger than the value supported by the implementation, then the behavior is CONSTRAINED UNPREDICTABLE and one of the following occurs:

- The instruction is UNDEFINED.
- The instruction performs cache maintenance on one of:
 - No cache lines.
 - A single arbitrary cache line.
 - Multiple arbitrary cache lines.

———— **Note** —————

This CONSTRAINED UNPREDICTABLE behavior applies, also, to the A64 cache maintenance by set/way instructions [DC CISW](#), [DC CSW](#), and [DC ISW](#).

K1.1.27 CONSTRAINED UNPREDICTABLE behavior for A32 and T32 system instructions in the base instruction set

This section lists the CONSTRAINED UNPREDICTABLE behavior for the different A32 and T32 system instructions.

———— **Note** —————

If an instruction can result in CONSTRAINED UNPREDICTABLE behavior that is not specific to that particular instruction, see the relevant section in this appendix for a description of the CONSTRAINED UNPREDICTABLE behavior.

SRS (T32)

For a description of this instruction and the encoding, see [SRS](#), [SRSDA](#), [SRSDB](#), [SRSIA](#), [SRSIB](#) on page F5-3464.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If the instruction specifies an illegal mode field, then one of the following behaviors must occur:
 - The instruction is UNDEFINED.
 - The instruction executes as a NOP.
 - R13 of the current mode is used.
 - The store occurs to an UNKNOWN address, and if the instruction specifies writeback, any general-purpose register that can be accessed without privilege violation from the current Exception level become UNKNOWN.

SRS (A32)

For a description of this instruction and the encoding, see [SRS](#), [SRSDA](#), [SRSDB](#), [SRSIA](#), [SRSIB](#) on page F5-3464.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If the instruction specifies an illegal mode field, then one of the following behaviors must occur:
 - The instruction is UNDEFINED.
 - The instruction executes as a NOP.
 - R13 of the current mode is used.
 - The store occurs to an UNKNOWN address, and if the instruction specifies writeback, any general-purpose register that can be accessed without privilege violation from the current Exception level become UNKNOWN.

SUBS PC, LR and related instructions (T32)

For a description of this instruction and the encoding, see the exception return form of *SUB, SUBS (immediate)* on page F5-3560.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If this instruction is executed in User mode or in System mode, then one of the following behaviors must occur:
 - The instruction is UNDEFINED.
 - The instruction executes as a NOP.
- If the instruction transfers an illegal mode encoding to *PSTATE.M*, then this invokes the illegal exception return.

———— **Note** —————

An illegal mode encoding is either an unallocated mode encoding or one that is not accessible at the current Exception level.

For this encoding:

- If *hw2[3:0]* are *0b1110*, and the instruction is executed when not in Hyp mode, System mode, or User mode, then one of the following behaviors must occur:
 - The instruction is UNDEFINED.
 - The instruction is treated as a NOP.
 - The instruction is treated as if *hw2[3:0]* are *0b1110*.
 - The program counter is set using the value in the register specified by *hw2[3:0]*.

SUBS PC, LR and related instructions (A32)

For a description of this instruction and the encoding, see the exception return forms of *MOV, MOVS (register)* on page F5-3260 and *SUB, SUBS (immediate)* on page F5-3560.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If this instruction is executed in User mode or in System mode, then one of the following behaviors must occur:
 - The instruction is UNDEFINED.
 - The instruction executes as a NOP.
- If the instruction transfers an illegal mode encoding to *PSTATE.M*, then this invokes the illegal exception return.

———— **Note** —————

An illegal mode encoding is either an unallocated mode encoding or one that is not accessible at the current Exception level.

K1.1.28 CONSTRAINED UNPREDICTABLE behavior, A32 and T32 Advanced SIMD and floating-point instructions

This section lists the CONSTRAINED UNPREDICTABLE behavior for the different A32 and T32 Advanced SIMD and floating-point instructions listed in [Alphabetical list of floating-point and Advanced SIMD instructions on page F6-3680](#).

Note

- The pseudocode used in this section to describe cases that can result in CONSTRAINED UNPREDICTABLE behavior does not necessarily match the encoding specific pseudocode for a specific instruction.
- If an instruction can result in CONSTRAINED UNPREDICTABLE behavior that is not specific to that particular instruction, see the relevant section in this appendix for a description of the CONSTRAINED UNPREDICTABLE behavior.

VCVT (between floating-point and fixed-point)

For a description of this instruction and the encoding, see [VCVT \(between floating-point and fixed-point, floating-point\) on page F6-3819](#).

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VLD1 (multiple single elements)

For a description of this instruction and the encoding, see [VLD1 \(multiple single elements\) on page F6-3889](#).

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VLD1 (single element to all lanes)

For a description of this instruction and the encoding, see [VLD1 \(single element to all lanes\) on page F6-3886](#).

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VLD2 (multiple 2-element structures)

For a description of this instruction and the encoding, see [VLD2 \(multiple 2-element structures\) on page F6-3906](#).

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VLD2 (single 2-element structure to one lane)

For a description of this instruction and the encoding, see [VLD2 \(single 2-element structure to one lane\) on page F6-3897](#).

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VLD2 (single 2-element structure to all lanes)

For a description of this instruction and the encoding, see [VLD2 \(single 2-element structure to all lanes\)](#) on page F6-3903.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VLD3 (multiple 3-element structures)

For a description of this instruction and the encoding, see [VLD3 \(multiple 3-element structures\)](#) on page F6-3920.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VLD3 (single 3-element structure to one lane)

For a description of this instruction and the encoding, see [VLD3 \(single 3-element structure to one lane\)](#) on page F6-3911.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VLD3 (single 3-element structure to all lanes)

For a description of this instruction and the encoding, see [VLD3 \(single 3-element structure to all lanes\)](#) on page F6-3917.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VLD4 (multiple 4-element structures)

For a description of this instruction and the encoding, see [VLD4 \(multiple 4-element structures\)](#) on page F6-3932.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VLD4 (single 4-element structure to one lane)

For a description of this instruction and the encoding, see [VLD4 \(single 4-element structure to one lane\)](#) on page F6-3923.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VLD4 (single 4-element structure to all lanes)

For a description of this instruction and the encoding, see [VLD4 \(single 4-element structure to all lanes\)](#) on page F6-3929.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VLDM

For a description of this instruction and the encoding, see [VLDM, VLDMDB, VLDMIA](#) on page F6-3935.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VMOV (between two general-purpose registers and two single-precision registers)

For a description of this instruction and the encoding, see [VMOV \(between two general-purpose registers and two single-precision registers\)](#) on page F6-4008.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VMOV (between two general-purpose registers and a doubleword floating-point register)

For a description of this instruction and the encoding, see [VMOV \(between two general-purpose registers and a doubleword floating-point register\)](#) on page F6-3988.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VST1 (multiple single elements)

For a description of this instruction and the encoding, see [VST1 \(multiple single elements\)](#) on page F6-4231.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VST2 (multiple 2-element structures)

For a description of this instruction and the encoding, see [VST2 \(multiple 2-element structures\)](#) on page F6-4245.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VST2 (single 2-element structure from one lane)

For a description of this instruction and the encoding, see [VST2 \(single 2-element structure from one lane\)](#) on page F6-4239.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VST3 (multiple 3-element structures)

For a description of this instruction and the encoding, see [VST3 \(multiple 3-element structures\)](#) on page F6-4256.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VST3 (single 3-element structure from one lane)

For a description of this instruction and the encoding, see [VST3 \(single 3-element structure from one lane\)](#) on page F6-4250.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VST4 (multiple 4-element structures)

For a description of this instruction and the encoding, see [VST4 \(multiple 4-element structures\)](#) on page F6-4265.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VST4 (single 4-element structure from one lane)

For a description of this instruction and the encoding, see [VST4 \(single 4-element structure from one lane\)](#) on page F6-4259.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VSTM

For a description of this instruction and the encoding, see [VSTM, VSTMDB, VSTMIA](#) on page F6-4268.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

K1.1.29 CONSTRAINED UNPREDICTABLE behaviors associated with the VTCR

The following subsections describe the CONSTRAINED UNPREDICTABLE behavior associated with programming the VTCR:

- *Misprogramming VTCR.S.*
- *Misprogramming VTCR.{SL0, T0SZ}.*

Misprogramming VTCR.S

VTCR.S must be programmed to the value of T0SZ[3], or the effect is CONSTRAINED UNPREDICTABLE. For the ARMv8-A architecture, if VTCR.S is not programmed correctly, then the VTCR.T0SZ value is treated as an UNKNOWN value.

———— Note —————

The CONSTRAINED UNPREDICTABLE behavior described in *Misprogramming VTCR.{SL0, T0SZ}* means the UNKNOWN VTCR.T0SZ value might generate a Translation fault.

Misprogramming VTCR.{SL0, T0SZ}

If the stage 2 input address size, as programmed in VTCR.T0SZ, is out of range with respect to the starting level, as programmed in the VTCR.SL0 field, or the VTCR.SL0 field is programmed to a reserved value, then at the time of a translation walk that uses the stage 2 translation, a stage 2 level 1 Translation Fault is generated.

K1.1.30 CONSTRAINED UNPREDICTABLE behavior of EL2 features

The following sections describe CONSTRAINED UNPREDICTABLE behavior that can occur in an implementation that includes EL2 where EL2 can use AArch32:

- *ERET in User mode or System mode.*
- *Accessing Hyp mode from outside Hyp mode.*
- *Modifying PSTATE.M when in Hyp mode on page K1-6115*
- *Use of Hyp mode in Secure state on page K1-6115.*
- *Execution of Load/Store unprivileged instructions in Hyp mode on page K1-6115.*
- *Exception return to Hyp mode on page K1-6115.*
- *Accessing registers that cannot be accessed using MSR/MRS instructions on page K1-6115.*
- *Memory type handling on page K1-6116.*
- *Hyp mode TLB maintenance instructions on page K1-6116.*
- *Hyp mode VA to PA address translation instructions on page K1-6116.*
- *Stage 1 default memory type on page K1-6116.*
- *Trapping of general exceptions to Hyp mode on page K1-6116.*
- *Prevention of rootkits using Hyp mode or Secure state on page K1-6117.*
- *HVC on page K1-6117.*
- *MSR/MRS Banked registers on page K1-6117.*

ERET in User mode or System mode

If ERET is executed in User mode or System mode, it behaves as described in *SUBS PC, LR and related instructions (T32) on page K1-6109.*

Accessing Hyp mode from outside Hyp mode

Attempting to change into Hyp mode or out of Hyp mode using the MSR or CPS instruction invokes the ARMv8 illegal exception return by not changing the mode, and setting PSTATE.IL to 1.

SRS using the Hyp mode SP from Non-secure modes other than Hyp mode, or from Secure state, is handled as described in *SRS (T32) on page K1-6108* and *SRS (A32) on page K1-6108.*

Modifying PSTATE.M when in Hyp mode

Attempting to change into Hyp mode or out of Hyp mode using the MSR or CPS instruction invokes the ARMv8 illegal exception return by not changing the mode, and setting PSTATE.IL to 1.

SRS using the Hyp mode SP from Non-secure modes other than Hyp mode, or from Secure state, is handled as described in [SRS \(T32\) on page K1-6108](#) and [SRS \(A32\) on page K1-6108](#).

Use of Hyp mode in Secure state

Attempting to change into Hyp mode or out of Hyp mode using the MSR or CPS instruction invokes the ARMv8 illegal exception return by not changing the mode, and setting PSTATE.IL to 1.

SRS using the Hyp mode SP from Non-secure modes other than Hyp mode, or from Secure state, is handled as described in [SRS \(T32\) on page K1-6108](#) and [SRS \(A32\) on page K1-6108](#).

Execution of Load/Store unprivileged instructions in Hyp mode

If LDRT, LDRSHT, LDRHT, LDRSBT, LDRBT, STRT, STRHT or STRBT are executed in Hyp mode, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the equivalent, corresponding LDR, LDRSH, LDRH, LDRSB, LDRB, STR, STRH or STRB instruction in Hyp mode.

Exception return to Hyp mode

Exception returns to Hyp mode when SCR.NS == 0 or from a Non-secure PL1 mode invokes the ARMv8 illegal exception return.

Accessing registers that cannot be accessed using MSR/MRS instructions

The following MSR and MRS instructions can lead to CONSTRAINED UNPREDICTABLE behavior:

```
MSR <Rm>_<mode>, <Rn>
MSR SPSR_<mode>, <Rn>
MSR ELR_hyp, <Rn>
MRS <Rn>, <Rm>_<mode>
MRS <Rn>, SPSR_<mode>
MRS <Rn>, ELR_hyp
```

If these instructions are executed in either Secure or Non-secure User mode, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.

If the MSR and MRS instructions attempt to access a register that cannot be legally accessed, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- For MRS instructions, the destination general-purpose register becomes UNKNOWN.
- For MSR instructions, if the register specified could be accessed from the current mode by other mechanisms, then this register is UNKNOWN. Otherwise the instruction executes as a NOP.

Memory type handling

If the attributes for a memory location after combining stage 1 and stage 2 of a translation regime is Normal Inner Non-cacheable, Outer Non-cacheable, then the shareability attributes after combining the two stages of translation is Outer Shareable.

Hyp mode TLB maintenance instructions

If a [TLBIMVAH](#), [TLBIMVALH](#), [TLBIMVAHIS](#), [TLBIMVALHIS](#), [TLBIALLH](#), [TLBIALLHIS](#), [TLBIALLNSNH](#), [TLBIALLNSNHIS](#), [TLBIIPAS2](#), [TLBIIPAS2L](#), [TLBIIPAS2IS](#), or [TLBIIPAS2LIS](#) instruction is executed in a Secure Privileged mode other than Monitor mode, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The instruction is executed as if it had been executed in Monitor mode.

For more information about these instructions see [The scope of TLB maintenance instructions on page G4-4641](#).

Hyp mode VA to PA address translation instructions

If an [ATS1HR](#) or [ATS1HW](#) instruction is executed in a Secure Privileged mode other than Monitor mode, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The instruction is executed as if it had been executed in Monitor mode.

For more information about these instructions see [Address translation instruction naming and operation summary on page G4-4682](#).

Stage 1 default memory type

If [HCR.DC](#) == 1, then the behavior of the PE when executing in a Non-secure mode other than Hyp mode is consistent with:

- [SCTLR.M](#) == 0, regardless of the actual value of [SCTLR.M](#), other than for the value returned by an explicit read of [SCTLR.M](#).
- [HCR.VM](#) == 1, regardless of the actual value of [HCR.VM](#), other than for an explicit read of this bit.

Trapping of general exceptions to Hyp mode

Attempting to perform an exception return to a Non-secure PL1 mode when [HCR.TGE](#) == 1 invokes an illegal exception return.

Attempting to change from Monitor mode to a Non-secure PL1 mode when [HCR.TGE](#) == 1 by executing a CPS or MSR instruction generates an Illegal Execution state exception, by not changing the mode, and setting [PSTATE.IL](#) to 1.

When EL3 is using AArch32, attempting to change from a Secure PL1 mode to a Non-secure PL1 mode when [HCR.TGE](#) is set, by changing [SCR.NS](#) from 0 to 1, results in no change of [SCR.NS](#).

Because taking an exception into Non-secure PL1 modes leads to a CONSTRAINED UNPREDICTABLE situation, the following additional properties apply when [HCR.TGE](#) == 1:

- All exceptions that would be routed to EL1 are routed to EL2.
- Non-secure [SCTLR.M](#) is treated as being 0, regardless of its actual value, other than for an explicit read of of this bit.
- [HCR.FMO](#), [HCR.IMO](#), and [HCR.AMO](#) are treated as being 1, regardless of their actual value, other than for an explicit read of these bits.

- All virtual interrupts are disabled.
- Any IMPLEMENTATION DEFINED mechanisms for signalling virtual interrupts are disabled.

Prevention of rootkits using Hyp mode or Secure state

If an **HVC** instruction is executed in Hyp mode when **SCR.HCE** == 0, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.

If an **SMC** instruction is executed in a Secure privileged mode when **SCR.SCD** == 1, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.

HVC

For a description of this instruction and the encoding, see [HVC on page F5-3123](#).

For the A1 encoding, if cond field != 1110, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction executes unconditionally.
- The instruction executes conditionally.

MSR/MRS Banked registers

[Encoding and use of Banked register transfer instructions on page F5-3674](#) identifies cases where attempted execution of an MRS (Banked register) or MSR (Banked register) was UNPREDICTABLE in ARMv7 and becomes CONSTRAINED UNPREDICTABLE in ARMv8. This includes cases where:

- The target register specified by the {R, SYSm} fields of the instruction encoding is not accessible from the PE mode in which the instruction was executed, see [Usage restrictions on the Banked register transfer instructions on page F5-3675](#).
- The instruction was executed specifying unallocated {R, SYSm} field values, see [Encoding the register argument in the Banked register transfer instructions on page F5-3676](#).

If one of these encodings for the MSR/MRS (Banked register) instructions is executed, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- An allocated MSR/MRS (Banked register) instruction is executed.

K1.1.31 Reserved values in System and memory-mapped registers and translation table entries

Unless otherwise stated, all unallocated or reserved values of fields with allocated values within the AArch32 System registers, memory-mapped registers, and translation table entries behave in one of the following ways:

- The encoding maps onto any of the allocated values, but otherwise does not cause CONSTRAINED UNPREDICTABLE behavior.
- The encoding causes effects that could be achieved by a combination of more than one of the allocated encodings.
- The encoding causes the field to have no functional effect.

———— **Note** —————

These constraints are identical to those for the equivalent AArch64 definitions, as given in [Reserved values in System and memory-mapped registers and translation table entries](#) on page K1-6133.

K1.1.32 CONSTRAINED UNPREDICTABLE behavior in Debug state

[Behavior in Debug state on page H2-5445](#) of this manual describes the CONSTRAINED UNPREDICTABLE behaviors that are specifically associated with Debug state.

K1.2 AArch64 CONSTRAINED UNPREDICTABLE behaviors

It contains the following sections:

- [Overview of the constraints on AArch64 UNPREDICTABLE behaviors.](#)
- [SBZ or SBO fields in A64 instructions.](#)
- [CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values on page K1-6120.](#)
- [CONSTRAINED UNPREDICTABLE behavior due to inadequate context synchronization on page K1-6120.](#)
- [Translation table base address alignment on page K1-6121.](#)
- [The Performance Monitors Extension on page K1-6121.](#)
- [Syndrome register handling for CONSTRAINED UNPREDICTABLE instructions treated as UNDEFINED on page K1-6122.](#)
- [Out of range virtual address on page K1-6122.](#)
- [Instruction fetches from Device memory on page K1-6122.](#)
- [Programming the CSSELR_EL1.Level for a cache level that is not implemented on page K1-6123.](#)
- [Crossing a page boundary with different memory types or Shareability attributes on page K1-6123.](#)
- [Crossing a peripheral boundary with a Device access on page K1-6123.](#)
- [CONSTRAINED UNPREDICTABLE behaviors with Load-Exclusive/Store-Exclusive pairs on page K1-6124.](#)
- [CONSTRAINED UNPREDICTABLE behavior for A64 instructions on page K1-6124.](#)
- [Out of range values of the Set/Way/Index fields in cache maintenance instructions on page K1-6133.](#)
- [Reserved values in System and memory-mapped registers and translation table entries on page K1-6133.](#)
- [CONSTRAINED UNPREDICTABLE behavior in Debug state on page K1-6133.](#)

K1.2.1 Overview of the constraints on AArch64 UNPREDICTABLE behaviors

The term UNPREDICTABLE describes a number of cases where the architecture has a feature that software must not use. For execution in AArch64 state, the ARMv8-A architecture specifies a narrow range of permitted behaviors. This range is the range of CONSTRAINED UNPREDICTABLE behavior. All implementations that are compliant with the architecture must follow the CONSTRAINED UNPREDICTABLE behavior.

———— **Note** —————

Software designed to be compatible with the ARMv8-A architecture must not rely on these CONSTRAINED UNPREDICTABLE cases being handled in any way other than those listed under the heading CONSTRAINED UNPREDICTABLE.

K1.2.2 SBZ or SBO fields in A64 instructions

Some A64 instructions have (0) or (1) in the instruction decode to indicate *should-be-zero*, SBZ, or *should-be-one*, SBO, as described in [Fixed values in AArch64 instruction and System register descriptions on page C2-151](#). Except for specific cases identified in [CONSTRAINED UNPREDICTABLE behaviors with Load-Exclusive/Store-Exclusive pairs on page K1-6124](#), if the instruction bit pattern of an instruction is executed with these fields not having the *should be* values, one of the following must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction operates as if the bit had the *should-be* value.
- Any destination registers of the instruction become UNKNOWN.

K1.2.3 CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values

The ARM architecture allows copies of control values or data values to be cached in a cache or TLB. This can lead to UNPREDICTABLE behavior if the cache or TLB has not been correctly invalidated following a change of the control or data values.

Unless explicitly stated otherwise, the behavior of the PE is consistent with one of:

- The old data or control value.
- The new data or control value.
- An amalgamation of the old and new data or control values.

In an implementation that includes ARMv8.2-TTCNP, this CONSTRAINED UNPREDICTABLE case can arise from misprogramming when setting TTBR.CnP to 1, as identified in the descriptions of the TTBR.CnP field. In this case, for a particular TTBR, the behavior of the PE is consistent with one of:

- The value of the translation table entry pointed to by that TTBR on one of the PEs within the Inner Shareable domain for which both the value of TTBR.CnP is 1 and the other conditions for sharing translation table entries pointed to by that TTBR are met.
- An amalgamation of the values of the translation table entries pointed to by that TTBR on two or more of the PEs within the Inner Shareable domain for which both the value of TTBR.CnP is 1 and the other conditions for sharing translation table entries pointed to by that TTBR are met.

———— Note ————

If the effective control or data value that determines the behavior of the PE results from the amalgamation of two or more values then that effective value must not generate a privilege violation. So, for example:

- Where the CONSTRAINED UNPREDICTABLE behavior occurs because inadequate invalidation of the TLB causes multiple hits in the TLB, the failure to invalidate the TLB by software executing at a given Exception level and Security state must not make it possible to access regions of memory with permissions or attributes that could not be accessed at that Exception level and Security state.
- Where the CONSTRAINED UNPREDICTABLE behavior occurs because of a programming error, on one or more PEs in the Inner Shareable domain, when using a TTBR.CnP value of 1 to share translation table entries, the misprogramming must not make it possible to access regions of memory with permissions or attributes that could not be accessed at the Exception level of that TTBR and the Security state corresponding to the translation table entries being shared.

Alternatively to this CONSTRAINED UNPREDICTABLE behavior, an implementation detecting multiple hits in a TLB might generate an exception, reporting the exception using the TLB conflict fault code, see [TLB conflict aborts on page D4-2118](#).

The choice between the behaviors might, in some implementations, vary for each use of a control or data value.

K1.2.4 CONSTRAINED UNPREDICTABLE behavior due to inadequate context synchronization

The ARM architecture requires that changes to System registers must be synchronized before they take effect. This can lead to UNPREDICTABLE behavior if the synchronization has not been performed.

In these cases, the behavior of the PE is consistent with the unsynchronized control value being either the old value or the new value.

Where multiple control values are updated but not yet synchronized, each control value might independently be the old value or the new value.

In addition, where the unsynchronized control value applies to different areas of functionality, or what an implementation has constructed as different areas of functionality, those areas might independently treat the control value as being either the old value or the new value.

The choice between these behaviors might, in some implementations, vary for each use of a control value.

K1.2.5 Translation table base address alignment

In the translation table base registers `TTBR0_EL1`, `TTBR1_EL1`, `TTBR0_EL2`, `VTTBR_EL2`, and `TTBR0_EL3`, register bits[48:*x*] hold the translation table base address, where *x* depends on the translation table granule size and the size of the addressed translation table, as described in *Memory translation granule size on page D4-2021*. Register bits[(*x*-1):0], **unless redefined for another purpose**, correspond to bits[(*x*-1):0] of the translation table base address and therefore are RES0.

———— **Note** ————

- When ARMv8.2-LPA is implemented and the 64KB granule size is used, register bits[5:2] are redefined to hold bits[51:48] of the translation table base address.
- When ARMv8.2-TTCNP is implemented register bit[0] is redefined as the CnP bit.

For these registers, if one or more RES0 bits in register bits [(*x*-1):0] does not have a value of 0, this can result in a misaligned translation table base address. In this case, one of the following behaviors must occur:

- The field that is defined to be RES0 is treated as if all the bits had a value of 0:
 - The value read back might be the value written or it might be zero.
- The calculation of an address for a translation table walk using those registers might be corrupted in those bits that are nonzero.

For more information, see the appropriate `TTBR.BADDR` field description.

K1.2.6 The Performance Monitors Extension

The following cases can cause CONSTRAINED UNPREDICTABLE behavior:

- If `PMSELR_EL0.SEL` is not equal to 31, and `PMSELR_EL0.SEL` is greater than or equal to `PMCR_EL0.N`, and the PE is executing in an Exception level in Secure state or in EL2.
- If `PMSELR_EL0.SEL` is not 31, and `PMSELR_EL0.SEL` is greater than or equal to `MDCR_EL2.HPMN`, and the PE is executing in an Exception level in Non-secure state other than in EL2.

In these cases, one of the following behaviors must occur:

- Accesses to `PMXEVTYPER_EL0` or `PMXVCNTR_EL0` from that state are UNDEFINED.
- Accesses to `PMXEVTYPER_EL0` or `PMXVCNTR_EL0` from that state behave as RAZ/WI.
- Accesses to `PMXEVTYPER_EL0` or `PMXVCNTR_EL0` from that state execute as NOPs.
- Accesses to `PMXEVTYPER_EL0` or `PMXVCNTR_EL0` from that state behave as if `PMSELR_EL0.SEL` contains an UNKNOWN value that is less than the number of counters accessible at the current Exception level and Security state.
- Accesses to `PMXEVTYPER_EL0` or `PMXVCNTR_EL0` from that state behave as if `PMSELR_EL0.SEL` is 31.
- In Non-secure state, for an access to `PMXEVTYPER_EL0` or `PMXVCNTR_EL0` from EL1 or a permitted access from EL0, if the counter is implemented but not accessible at the current Exception level, the register access is trapped to EL2. Accesses from EL0 are permitted when:
 - EL1 is using AArch32 and the value of `PMUSERENR.EN` is 1.
 - EL1 is using AArch64 and the value of `PMUSERENR_EL0.EN` is 1.

If `PMSELR_EL0.SEL` is equal to 31, then one of the following behaviors must occur:

- Accesses to `PMXVCNTR_EL0` are UNDEFINED.
- Accesses to `PMXVCNTR_EL0` behave as RAZ/WI.
- Accesses to `PMXVCNTR_EL0` execute as NOPs.

- Accesses to `PMXEVCNTR_EL0` behave as if `PMSELR_EL0.SEL` contains an UNKNOWN value that is less than the number of counters accessible at the current Exception level and Security state.

If `MDCR_EL2.HPMN` is set to 0, or to a value larger than `PMCR_EL0.N`, then the following CONSTRAINED UNPREDICTABLE behavior applies:

- The value returned by a direct read of `MDCR_EL2.HPMN` is UNKNOWN.
- Either:
 - An UNKNOWN number of counters are reserved for EL2 use. That is, the PE behaves as if `MDCR_EL2.HPMN` is set to an UNKNOWN non-zero value less than `PMCR_EL0.N`.
 - All counters are reserved for EL2 use, meaning no counters are accessible from Non-secure EL1 and Non-secure EL0.

K1.2.7 Syndrome register handling for CONSTRAINED UNPREDICTABLE instructions treated as UNDEFINED

When a CONSTRAINED UNPREDICTABLE instruction is treated as UNDEFINED, `ESR_ELx` is UNKNOWN.

———— **Note** ————

The value written to `ESR_ELx` must be consistent with a value that could be created as the result of an exception from the same Exception level that generated the exception, but was the result of a situation that is not CONSTRAINED UNPREDICTABLE at that Exception level. This is to avoid a possible privilege violation.

K1.2.8 Out of range virtual address

If the PE executes a load or store instruction with tagged addressing disabled in the current translation regime, and where the computed virtual address, total access size, and alignment mean that it accesses the bytes at `0xFFFF FFFF FFFF FFFF` and `0x0000 0000 0000 0000`, then the bytes that appear to be from `0x0000 0000 0000 0000` onwards are accessed at an UNKNOWN address.

If the PE executes a load or store instruction with tagged addressing enabled in the current translation regime, and where the computed address, total access size, and alignment mean that it accesses the bytes at `0xFFFF FFFF FFFF FFFF` and `0x0000 0000 0000 0000`, then the bytes that appear to be from `0x0000 0000 0000 0000` onwards are accessed at an UNKNOWN address and the tags associated with address also become UNKNOWN.

———— **Note** ————

Because of program counter alignment constraints, it is impossible for a PE to fetch an A64 instruction that includes both the byte at virtual address `0xFFFF FFFF FFFF FFFF` and the byte at virtual address `0x0000 0000 0000 0000`.

K1.2.9 Instruction fetches from Device memory

Instruction fetches from Device memory are CONSTRAINED UNPREDICTABLE.

If a location in memory has the Device attribute and is not marked as execute-never, then an implementation might perform speculative instruction accesses to this memory location at times when address translation is enabled.

If a branch causes the program counter to point to an area of memory with the Device attribute that is not marked as execute-never for the current Exception level for instruction fetches, then an implementation must perform one of the following behaviors:

- It treats the instruction fetch as if it were to a memory location with the Normal, Non-cacheable attribute.
- It generates a Permission fault.

K1.2.10 Programming the CSSELR_EL1.Level for a cache level that is not implemented

If the CSSELR_EL1.Level is programmed to a cache level that is not implemented, then a read of CSSELR_EL1 returns an UNKNOWN value in CSSELR_EL1.Level.

If the CSSELR_EL1.Level is programmed to a cache level that is not implemented, then on a read of CCSIDR_EL1 an implementation must perform one of the following behaviors:

- The CCSIDR_EL1 read executes as a NOP.
- The CCSIDR_EL1 read is UNDEFINED.
- The CCSIDR_EL1 read returns an UNKNOWN value.

K1.2.11 Crossing a page boundary with different memory types or Shareability attributes

A memory access from a load or store instruction that crosses a page boundary to a memory location that has a different memory type or Shareability attribute results in CONSTRAINED UNPREDICTABLE behavior. In this case, the implementation must perform one of the following behaviors:

- All memory accesses generated by the instruction use the memory type and Shareability attributes associated with the first address accessed by the instruction.
- All memory accesses generated by the instruction use the memory type and Shareability attributes associated with the last address accessed by the instruction.
- Each memory access generated by the instruction uses the memory type and Shareability attribute associated with its own address.
- The instruction generates an Alignment fault caused by the memory type.

For the Non-secure EL1&0 translation regime:

- If the stage 1 translation generated the mismatch then the resulting exception is taken to EL1.
 - If the stage 2 translation generated the mismatch then the resulting exception is taken to EL2.
 - If both stages of translation generate the mismatch then the exception can be taken to either EL1 or EL2.
- The instruction executes as a NOP.

K1.2.12 Crossing a peripheral boundary with a Device access

Performing memory accesses from one load or store instruction to Device memory that crosses a boundary corresponding to the smallest translation granule size of the implementation causes CONSTRAINED UNPREDICTABLE behavior. In this case, the implementation performs one of the following behaviors:

- All memory accesses generated by the instruction are performed as if the boundary has no effect on the memory accesses.
- All memory accesses generated by the instruction are performed as if the boundary has no effect on the memory accesses except that there is no guarantee of ordering between memory accesses.
- The instruction generates an alignment fault caused by the memory type.

For the Non-secure EL1&0 translation regime:

- If the stage 1 translation causes the boundary to be crossed then the resulting exception is taken to EL1.
 - If the stage 2 translation causes the boundary to be crossed then the resulting exception is taken to EL2.
 - If both stages of translation cause the boundary to be crossed then the resulting exception can be taken to either EL1 or EL2.
- The instruction executes as a NOP.

———— **Note** —————

The boundary referred to is between two Device memory regions that are both:

- Of the size of the smallest implemented translation granule.
- Aligned to the size of the smallest implemented translation granule.

K1.2.13 CONSTRAINED UNPREDICTABLE behaviors with Load-Exclusive/Store-Exclusive pairs

[Load-Exclusive and Store-Exclusive instruction usage restrictions on page B2-128](#) defines a Load-Exclusive/Store-Exclusive pair, and identifies various CONSTRAINED UNPREDICTABLE behaviors associated with using Load-Exclusive/Store-Exclusive pairs. In summary, these cases are:

- The target virtual address of a StoreExc1 instruction is different from the virtual address of the preceding LoadExc1 instruction in the same thread of execution.
- The transaction size of a StoreExc1 instruction is different from the transaction size of the preceding LoadExc1 instruction in the same thread of execution.
- The StoreExc1 instruction accesses a different number of registers than the preceding LoadExc1 instruction in the same thread of execution.
- The memory attributes for a StoreExc1 instruction are different from the memory attributes for the preceding LoadExc1 instruction in the same thread of execution, either:
 - Because the translation of the accessed address changes between the LoadExc1 instruction and the StoreExc1 instruction.
 - Because the LoadExc1 instruction and the StoreExc1 instruction use different virtual addresses, with different attributes, that point to the same physical address.

In addition, the effect of a data or unified cache invalidate, clean, or clean and invalidate instruction on a local or global Exclusives monitor that is in the Exclusive Access state is CONSTRAINED UNPREDICTABLE.

See the descriptions in [Load-Exclusive and Store-Exclusive instruction usage restrictions on page B2-128](#) for the permitted behavior in each of these cases, and any constraints that might apply to whether the case is CONSTRAINED UNPREDICTABLE.

K1.2.14 CONSTRAINED UNPREDICTABLE behavior for A64 instructions

This section lists the CONSTRAINED UNPREDICTABLE behavior for the different A64 instructions listed in [Chapter C6 A64 Base Instruction Descriptions](#) and [Chapter C7 A64 Advanced SIMD and Floating-point Instruction Descriptions](#).

LDAXP

For a description of this instruction and the encoding, see [LDAXP on page C6-641](#).

CONSTRAINED UNPREDICTABLE behavior

If $t == t2$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs a load using the specified addressing mode, and the base register is set to an UNKNOWN value.

LDNP

For a description of this instruction and the encoding, see [LDNP on page C6-662](#).

CONSTRAINED UNPREDICTABLE behavior

If $t == t2$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs a load using the specified addressing mode, and the base register is set to an UNKNOWN value.

LDNP (SIMD&FP)

For a description of this instruction and the encoding, see [LDNP \(SIMD&FP\) on page C7-1353](#).

CONSTRAINED UNPREDICTABLE behavior

If $t == t2$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs a load using the specified addressing mode, and the base register is set to an UNKNOWN value.

LDP

For a description of this instruction and the encoding, see [LDP on page C6-664](#).

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and $(t == n \mid t2 == n) \ \&\& \ n \neq 31$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs a load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

If $t == t2$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs all of the loads using the specified addressing mode, and the register loaded is set to an UNKNOWN value.

Note

Pre-indexed addressing and post-indexed addressing imply writeback.

LDP (SIMD&FP)

For a description of this instruction and the encoding, see [LDP \(SIMD&FP\) on page C7-1355](#).

CONSTRAINED UNPREDICTABLE behavior

If $t == t2$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.

- The instruction performs a load using the specified addressing mode, and the base register is set to an UNKNOWN value.

LDPSW

For a description of this instruction and the encoding, see [LDPSW](#) on page C6-667.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and $(t == n \ || \ t2 == n) \ \&\& \ n \ != \ 31$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs a load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

If $t == t2$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs all of the loads using the specified addressing mode, and the register loaded is set to an UNKNOWN value.

Note

Pre-indexed addressing and post-indexed addressing imply writeback.

LDR (immediate)

For a description of this instruction and the encoding, see [LDR \(immediate\)](#) on page C6-670.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and $n == t \ \&\& \ n \ != \ 31$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

Note

Pre-indexed addressing and post-indexed addressing imply writeback.

LDRB (immediate)

For a description of this instruction and the encoding, see [LDRB \(immediate\)](#) on page C6-677.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and $n == t \ \&\& \ n \neq 31$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

———— **Note** —————

Pre-indexed addressing and post-indexed addressing imply writeback.

LDRH (immediate)

For a description of this instruction and the encoding, see [LDRH \(immediate\)](#) on page C6-681.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and $n == t \ \&\& \ n \neq 31$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

———— **Note** —————

Pre-indexed addressing and post-indexed addressing imply writeback.

LDRSB (immediate)

For a description of this instruction and the encoding, see [LDRSB \(immediate\)](#) on page C6-685.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and $n == t \ \&\& \ n \neq 31$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

———— **Note** —————

Pre-indexed addressing and post-indexed addressing imply writeback.

LDRSH (immediate)

For a description of this instruction and the encoding, see [LDRSH \(immediate\)](#) on page C6-690.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and $n \neq t$ & $n \neq 31$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

———— **Note** —————

Pre-indexed addressing and post-indexed addressing imply writeback.

LDRSW (immediate)

For a description of this instruction and the encoding, see [LDRSW \(immediate\)](#) on page C6-695.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and $n \neq t$ & $n \neq 31$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

———— **Note** —————

Pre-indexed addressing and post-indexed addressing imply writeback.

LDXP

For a description of this instruction and the encoding, see [LDXP](#) on page C6-748.

CONSTRAINED UNPREDICTABLE behavior

If $t \neq t2$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs a load using the specified addressing mode, and the base register is set to an UNKNOWN value.

STP

For a description of this instruction and the encoding, see [STP on page C6-867](#).

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and $(t == n \ || \ t2 == n) \ \&\& \ n \ != \ 31$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs a store using the specified addressing mode but the value stored is UNKNOWN.

———— **Note** —————

Pre-indexed addressing and post-indexed addressing imply writeback.

STLXP

For a description of this instruction and the encoding, see [STLXP on page C6-856](#).

CONSTRAINED UNPREDICTABLE behavior

If $s == t \ || \ (s == t2)$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to the specified address, but the value stored is UNKNOWN.

If $s == n \ \&\& \ n \ != \ 31$ then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to an UNKNOWN address.

STLXR

For a description of this instruction and the encoding, see [STLXR on page C6-859](#).

CONSTRAINED UNPREDICTABLE behavior

If $s == t$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to the specified address, but the value stored is UNKNOWN.

If $s == n \ \&\& \ n \ != \ 31$ then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to an UNKNOWN address.

STLXRB

For a description of this instruction and the encoding, see [STLXRB](#) on page C6-861.

CONSTRAINED UNPREDICTABLE behavior

If $s == t$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to the specified address, but the value stored is UNKNOWN.

If $s == n$ && $n != 31$ then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to an UNKNOWN address.

STLXRH

For a description of this instruction and the encoding, see [STLXRH](#) on page C6-863.

CONSTRAINED UNPREDICTABLE behavior

If $s == t$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to the specified address, but the value stored is UNKNOWN.

If $s == n$ && $n != 31$ then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to an UNKNOWN address.

STR (immediate)

For a description of this instruction and the encoding, see [STR \(immediate\)](#) on page C6-870.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and $n == t$ && $n != 31$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs a store using the specified addressing mode but the value stored is UNKNOWN.

———— **Note** —————

Pre-indexed addressing and post-indexed addressing imply writeback.

STRB (immediate)

For a description of this instruction and the encoding, see [STRB \(immediate\)](#) on page C6-875.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and $n == t$ && $n != 31$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs a store using the specified addressing mode but the value stored is UNKNOWN.

———— Note —————

Pre-indexed addressing and post-indexed addressing imply writeback.

STRH (immediate)

For a description of this instruction and the encoding, see [STRH \(immediate\)](#) on page C6-879.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and $n == t$ && $n != 31$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs a store using the specified addressing mode but the value stored is UNKNOWN.

———— Note —————

Pre-indexed addressing and post-indexed addressing imply writeback.

STXP

For a description of this instruction and the encoding, see [STXP](#) on page C6-920.

CONSTRAINED UNPREDICTABLE behavior

If $s == t$ || ($s == t2$), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to the specified address, but the value stored is UNKNOWN.

If $s == n$ && $n != 31$ then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to an UNKNOWN address.

STXR

For a description of this instruction and the encoding, see [STXR on page C6-922](#).

CONSTRAINED UNPREDICTABLE behavior

If $s == t$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to the specified address, but the value stored is UNKNOWN.

If $s == n$ && $n != 31$ then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to an UNKNOWN address.

STXRB

For a description of this instruction and the encoding, see [STXRB on page C6-924](#).

CONSTRAINED UNPREDICTABLE behavior

If $s == t$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to the specified address, but the value stored is UNKNOWN.

If $s == n$ && $n != 31$ then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to an UNKNOWN address.

STXRH

For a description of this instruction and the encoding, see [STXRH on page C6-926](#).

CONSTRAINED UNPREDICTABLE behavior

If $s == t$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to the specified address, but the value stored is UNKNOWN.

If $s == n$ && $n != 31$ then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to an UNKNOWN address.

K1.2.15 Out of range values of the Set/Way/Index fields in cache maintenance instructions

In the cache maintenance by set/way instructions [DC CISW](#), [DC CSW](#), and [DC ISW](#), if any set/way/index argument is larger than the value supported by the implementation, then the behavior is CONSTRAINED UNPREDICTABLE and one of the following occurs:

- The instruction is UNDEFINED.
- The instruction performs cache maintenance on one of:
 - No cache lines.
 - A single arbitrary cache line.
 - Multiple arbitrary cache lines.

———— **Note** —————

This CONSTRAINED UNPREDICTABLE behavior applies, also, to the AArch32 cache maintenance by set/way instructions [DCCISW](#), [DCCSW](#), and [DCISW](#).

K1.2.16 Reserved values in System and memory-mapped registers and translation table entries

Unless otherwise stated in this manual, all unallocated or reserved values of fields with allocated values within AArch64 System registers, memory-mapped registers, and translation table entries behave in one of the following ways:

- The unallocated value maps onto any of the allocated values, but otherwise does not cause CONSTRAINED UNPREDICTABLE behavior.
- The unallocated value causes effects that could be achieved by a combination of more than one of the allocated values.
- The unallocated value causes the field to have no functional effect.

———— **Note** —————

These constraints are identical to those for the equivalent AArch32 definitions, as given in [Reserved values in System and memory-mapped registers and translation table entries on page K1-6117](#).

K1.2.17 CONSTRAINED UNPREDICTABLE behavior in Debug state

[Behavior in Debug state on page H2-5445](#) of this manual describes the CONSTRAINED UNPREDICTABLE behaviors that are specifically associated with Debug state.

Appendix K2

Recommended External Debug Interface

This appendix describes the recommended external debug interface. It contains the following sections:

- [About the recommended external debug interface on page K2-6136.](#)
- [PMUEVENT bus on page K2-6139.](#)
- [Recommended authentication interface on page K2-6140.](#)
- [Management registers and CoreSight compliance on page K2-6141.](#)

———— **Note** —————

This recommended external debug interface specification is not part of the ARM architecture specification. Implementers and users of the ARMv8 architecture must not consider this appendix as a requirement of the architecture. It is included as an appendix to this manual only:

- As reference material for users of ARM products that implement this interface.
- As an example of how an external debug interface might be implemented.

The inclusion of this appendix is no indication of whether any ARM products might, or might not, implement this external debug interface. For details of the implemented external debug interface you must always see the appropriate product documentation.

K2.1 About the recommended external debug interface

See the *Note* on the first page of this appendix for information about the architectural status of this recommended debug interface.

This specification provides a recommended external debug interface for ARMv8 to define a standard set of connections for validation environments. In general, the connection between components, such as between the PE and Trace extension, is not described here, although the table does include the signals for the CTI connection.

[Table K2-1](#) shows the signals in the recommended interface.

Table K2-1 Recommended debug interface signals

Name	Direction	Description	Notes
DBGEN	In	External debug enable	-
SPIDEN	In	Secure privileged external debug enable Secure privileged self-hosted debug enable	- Only in Secure AArch32 modes when enabled by MDCR_EL3.SPD32
NIDEN	In	External profiling and trace enable	-
SPNIDEN	In	Secure external profiling and trace enable	-
EDBGRQ	In	External halt request	Provided for legacy connections only.
DBGACK	Out	External halt request acknowledge	
COMMIRQ	Out	DCC interrupt	Interface to an interrupt controller. See Interrupt-driven use of the DCC on page H4-5514 and the pseudocode for function CheckForDCCInterrupts() .
PMUIRQ	Out	Performance Monitor overflow	Interface to an interrupt controller. See Behavior on overflow on page D5-2142 .
COMMRX	Out	DTRRX is full	Provided for legacy connection to an interrupt controller only. See Interrupt-driven use of the DCC on page H4-5514 and the pseudocode for function CheckForDCCInterrupts() .
COMMTX	Out	DTRTX is empty	
PMUEVENT[n:0]	Out	Performance Monitors event bus	See PMUEVENT bus on page K2-6139 .
DBGNOPWRDWN	Out	Core no powerdown request	Interface to a power controller. See DBGPRCR_EL1.CORENPDRQ .
DBGPWRUPREQ	Out	Core powerup request	Interface to a power controller. See EDPRCR.COREPURQ .
DBGRSTREQ	Out	Warm reset request	Interface to a power controller. See EDPRCR.CWRR .
DBGBUSCANCELREQ	Out	All asynchronous entry to Debug state	Extension to the bus interface. See EDRCR.CBRRQ .
DBGPWRDUP	In	Core powerup status	Interface to a power controller. See EDPRSR.PU .
DBGROMADDR[n:12]	In	MDRAR_EL1.ROMADDR	<i>n</i> depends on the size of the physical address space.

Table K2-1 Recommended debug interface signals (continued)

Name	Direction	Description	Notes	
DBGROMADDRV	In	MDRAR_EL1 . Valid	-	
PRESETDBG	In	External debug reset	-	
CPUPORESET	In	Cold reset	-	
CORERESET	In	Warm reset	-	
PSELDBG	In	Debug APB slave port	For details see <i>AMBA APB3</i> . ARM recommends a single slave port for all integrated debug components. PADDRDBG31 distinguishes memory-mapped and DAP accesses: 0 Memory-mapped access 1 DAP access	
PENABLEDBG	In			
PWRITDBG	In			
PRDATADBG[31:0]	Out			
PWDATADBG[31:0]	In			
PADDRDBG[n:2] ^a	In			
PREADYDBG	Out			
PSLVERRDBG	Out			
PCLKDBG	In			
PCLKENDBG	In			
CTICHIN	In	CoreSight channel interface		For details, see the <i>ARM® CoreSight™ Architecture Specification</i> . The ACK signals are not required if the channel interface is synchronous.
CTICHOUTACK	In			
CTICHOUT	Out			
CTICHINACK	Out			
CTHIRQ	Out	CTI interrupt, see Description and allocation of CTI triggers on page H5-5525	Implements a handshake for an edge-sensitive interrupt.	
CTHIRQACK	In			
ATDATA[nx8-1:0]	Out	AMBA 4 ATB interface	For details, see the <i>AMBA 4 ATB Protocol Specification, ATBv1.0 and ATBv1.1</i> . Only available if the OPTIONAL Trace extension is implemented.	
ATBYTES[n-1:0]	Out			
ATID[6:0]	Out			
ATREADY	In			
ATVALID	Out			
AFREADY	Out			
AFVALID	Out			
SYNCREQ	In			
ATCLK	In			
ATCLKEN	In			
ATRESET	In			

a. The value of *n* depends on the size of the address space occupied by the Debug port.

Figure K2-1 shows the recommended debug interface.

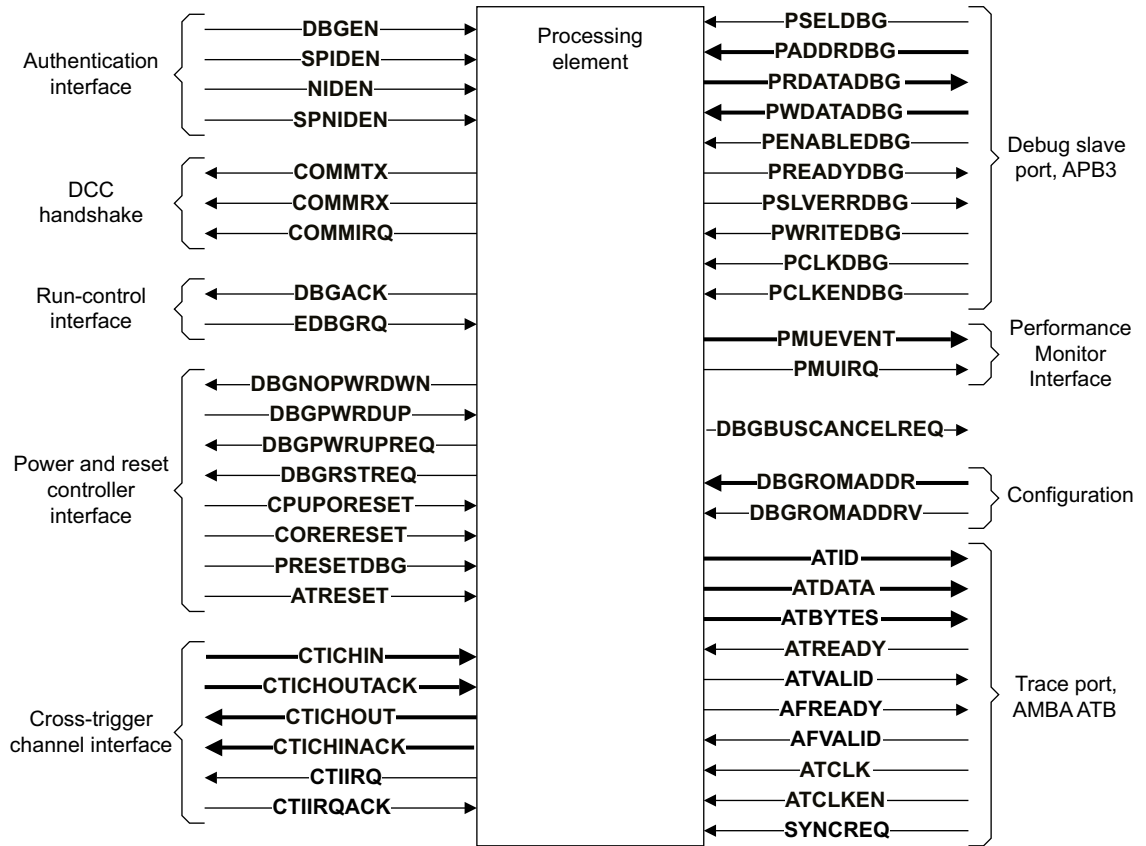

Figure K2-1 Recommended external debug interface, including the APB3 slave port

K2.2 PMUEVENT bus

The **PMUEVENT** bus exports Performance Monitor events from the PE to an on-chip agent. ARM recommends that it has the following characteristics:

- The bus is synchronous.
- The width of the bus is IMPLEMENTATION DEFINED.
- It is IMPLEMENTATION DEFINED which events are exported on the bus.
- Each exported event occupies a contiguous sub-field of the bus. ARM recommends that the sub-fields of the bus are occupied in the same order as the event numbers.
- If the event can only occur once per cycle, it occupies a single bit. If the event can occur more than once per cycle, it is IMPLEMENTATION DEFINED how the event is encoded. The encoding depends on constraints such as the designated use of the event bus and the number of pins available. For example, the event can be encoded:
 - As a count, using a plain binary number. This is the most useful encoding when exporting to an external counter. It is not a useful encoding for exporting to a Trace extension external input.
 - As a count, using thermometer encoding. This is the most useful encoding when exporting to a Trace extension.
 - Using a single bit encoding to indicate whether the event count is zero or nonzero. This is useful for exporting to an activity monitor where the number of pins is constrained.

If a Trace extension is implemented, the **PMUEVENT** bus is normally connected to the Trace extension using the external inputs. TRCEXTINSEL multiplexes a wide **PMUEVENT** bus to a narrow set of inputs. An external **PMUEVENT** bus might also be provided. For more information, contact ARM.

K2.3 Recommended authentication interface

An implementation of the ARMv8 architecture must support debug authentication described in [Required debug authentication on page H1-5432](#).

The details of the debug authentication interface are IMPLEMENTATION DEFINED, but ARM recommends the use of the CoreSight interface, which includes the following signals for external debug authentication:

- **DBGEN**.
- **SPIDEN**.
- **NIDEN**.
- **SPNIDEN**.

ARM recommends an interface in which **DBGEN** and **SPIDEN** are also used for self-hosted Secure debug authentication if either:

- EL3 is using AArch32 and `SDCR.SPD == 0b00`.
- Secure EL1 is using AArch32 and `MDCR_EL3.SPD32 == 0b00`.

If EL3 is not implemented and the PE is in Non-secure state, **SPIDEN** and **SPNIDEN** are not implemented, and the PE behaves as if these signals were tied LOW.

If EL3 is not implemented and the PE is in Secure state, **SPIDEN** is usually connected to **DBGEN** and **SPNIDEN** is connected to **NIDEN**, but this is not required. The recommended interface is defined as if all four signals are implemented.

How the authentication signals are driven is IMPLEMENTATION DEFINED. For example, the signals might be hard-wired, connected to fuses, or to an authentication module. The architecture permits PEs within a cluster to have independent authentication interfaces, but this is not required. ARM recommends that any Trace extension has the same authentication interface as the PE it is connected to.

[Table K2-2](#) shows the debug authentication pseudocode functions and the recommended implementations.

Table K2-2 Recommended implementation of debug enable pseudocode functions

Pseudocode function	Description	Implementation
<code>AArch32.SelfHostedSecurePrivilegedInvasiveDebugEnabled()</code>	Secure invasive self-hosted debug enabled in AArch32 state (legacy)	(DBGEN AND SPIDEN)
<code>ExternalSecureNoninvasiveDebugEnabled()</code>	Secure non-invasive debug enabled	(DBGEN OR NIDEN) AND (SPIDEN OR SPNIDEN)
<code>ExternalSecureInvasiveDebugEnabled()</code>	Secure invasive debug enabled	(DBGEN AND SPIDEN)
<code>ExternalNoninvasiveDebugEnabled()</code>	Non-secure non-invasive debug enabled	(DBGEN OR NIDEN)
<code>ExternalInvasiveDebugEnabled()</code>	Non-secure invasive debug enabled	DBGEN

The `Debug_authentication()` pseudocode function on [shared/debug on page J1-6006](#) defines the authentication signals **DBGEN**, **SPIDEN**, **NIDEN** and **SPNIDEN**.

K2.4 Management registers and CoreSight compliance

The CoreSight architecture requires the implementation of a set of management registers that occupy the memory map from 0xF00 upwards in each of the debug components.

CoreSight compliance and complete implementation of the management registers is OPTIONAL, but ARM recommends that the registers are implemented.

The CoreSight architecture specification recommends that any integration test registers are implemented starting from 0xEFC downwards. Each of the debug components has an IMPLEMENTATION DEFINED region from 0xE80 to 0xEFC for this purpose.

K2.4.1 Coresight interface register map

Table K2-3 shows the external management register maps for the following registers:

- ED** These are the external debug register.
- CTI** These are the Cross-trigger interface registers.
- PMU** These are the Performance Monitors registers.

Table K2-3 Coresight interface register map

Offset	Mnemonic			Name
	ED	CTI	PMU	
0xF00	EDITCTRL	CTIITCTRL	PMITCTRL	Integration Model Control registers
0xF04-0xF9C	-	-	-	Reserved, RES0
0xFA0	DBGCLAIMSET_EL1 ^a	CTICLAIMSET ^b	-	CLAIM Tag Set registers
0xFA4	DBGCLAIMCLR_EL1 ^a	CTICLAIMCLR ^b	-	CLAIM Tag Clear registers
0xFA8	EDDEVAFF0 ^a	CTIDEVAFF0 ^c	PMDEVAFF0	Device Affinity registers
0xFAC	EDDEVAFF1 ^a	CTIDEVAFF1 ^c	PMDEVAFF1	
0xFB0	EDLAR ^d	CTILAR ^d	PMLAR ^d	Lock Access register
0xFB4	EDLSR ^d	CTILSR ^d	PMLSR ^d	Lock Status register
0xFB8	DBGAUTHSTATUS_EL1 ^a	CTIAUTHSTATUS	PMAUTHSTATUS	Authentication Status register
0xFBC	EDDEVARCH	CTIDEVARCH	PMDEVARCH	Device Architecture register
0xFC0	EDDEVID2 ^a	CTIDEVID2 ^a	-	Device ID register
0xFC4	EDDEVID1 ^a	CTIDEVID1 ^a	-	
0xFC8	EDDEVID ^a	CTIDEVID ^a	PMDEVID ^a	
0xFCC	EDDEVTYPE	CTIDEVTYPE	PMDEVTYPE	Device Type register
0xFD0	EDPIDR4	CTIPIDR4	PMPIDR4	Peripheral ID registers
0xFD4-0xFDC	-	-	-	Reserved, RES0
0xFE0	EDPIDR0	CTIPIDR0	PMPIDR0	Peripheral ID registers
0xFE4	EDPIDR1	CTIPIDR1	PMPIDR1	
0xFE8	EDPIDR2	CTIPIDR2	PMPIDR2	
0xFEC	EDPIDR3	CTIPIDR3	PMPIDR3	

Table K2-3 Coresight interface register map (continued)

Offset	Mnemonic			Name
	ED	CTI	PMU	
0xFF0	EDCIDR0	CTICIDR0	PMCIDR0	Component ID registers
0xFF4	EDCIDR1	CTICIDR1	PMCIDR1	
0xFF8	EDCIDR2	CTICIDR2	PMCIDR2	
0xFFC	EDCIDR3	CTICIDR3	PMCIDR3	

- This register must always be implemented, regardless of whether the component is CoreSight compliant.
- If implemented, the number of CLAIM bits is IMPLEMENTATION DEFINED and can be discovered by reading CLAIMSET.
- If the CTI implements CTIV1, this register is not implemented. See the register description for details.
- The Software lock registers are defined as part of CoreSight compliance, but their contents depend on the type of access that is made and whether the OPTIONAL Software lock is implemented. See the register description for details.

K2.4.2 Management register access permissions

Access to the OPTIONAL Integration Control register (ITCTRL) is IMPLEMENTATION DEFINED.

If the Debug power domain is off, all register accesses return an error.

Otherwise, [Table K2-4 on page K2-6143](#), [Table K2-5 on page K2-6144](#), and [Table K2-6 on page K2-6145](#) show the response to accesses by the external debug interface to the CoreSight management registers. For definitions of the terms used in the tables, see [External debug interface register access permissions summary on page H8-5563](#).

———— Note —————

Access to the CoreSight management registers is not affected by the values of EDAD and EPMAD.

[Table K2-4 on page K2-6143](#), [Table K2-5 on page K2-6144](#), and [Table K2-6 on page K2-6145](#) include reserved management registers, because the CoreSight architecture requires that these registers are always RES0. The descriptions in [Reserved and unallocated registers on page H8-5563](#) does not apply to reserved management registers if the implementation is CoreSight compliant.

If OPTIONAL memory-mapped access to the external debug interface is supported, there are additional constraints on memory-mapped accesses. See [Register access permissions for memory-mapped accesses on page H8-5558](#).

The terms in [Table K2-4 on page K2-6143](#), [Table K2-5 on page K2-6144](#), and [Table K2-6 on page K2-6145](#) are defined as follows:

Domain This describes the power domain in which the register is logically implemented. Registers described as implemented in the Core power domain might be implemented in the Debug power domain, as long as they exhibit the required behavior.

Conditions This lists the conditions under which the access is attempted.
To determine the access permissions for a register, read these columns from left to right, and stop at first column which lists the condition as being true.

The conditions are:

Off [EDPRSR.PU](#) == 0. The Core power domain is completely off, or in low-power state. In these cases the Core power domain registers cannot be accessed.

———— Note —————

If debug power is off, then all external debug interface accesses return an error.

DLK [DoubleLockStatus\(\)](#) == TRUE. The OS Double Lock is locked.

OSLK [OSLSR.OSLK](#) == 1. The OS Lock is locked.

- Default** This provides the default access permissions, if there are no conditions that prevent access to the register.
- SLK** This provides the modified default access permissions for OPTIONAL memory-mapped accesses to the external debug interface if the OPTIONAL Software Lock is locked. See [Register access permissions for memory-mapped accesses on page H8-5558](#). For all other accesses, this column is ignored.

The access permissions are:

- This means that the default access permission applies. See the Default column, or the SLK column, if applicable.
- RO** This means that the register or field is read-only.
- RW** This means that the register or field is read/write. Individual fields within the register might be RO. See the relevant register description for details.
- RC** This means that the bit clears to 0 after a read.
- (SE)** This means that accesses to this register have indirect write side effects. A side effect occurs when a direct read or a direct write of a register creates an indirect write to the same register or to another register.
- WO** This means that the register or field is write-only.
- WI** This means that the register or field ignores writes.
- IMP DEF** This means that the access permissions are IMPLEMENTATION DEFINED.

Table K2-4 External debug interface access permissions, CoreSight registers (debug)

Offset	Register	Domain	Conditions (priority left to right)			Default	SLK

K2.4.3 Management register resets

Table K2-7 shows the management register resets. This table does not include:

- Read-only identification registers that have a fixed value from reset. These registers include those with the DEVAFFn, DEVARCH, DEVID{n}, DEVTYPE, PIDRn, and CIDRn mnemonics.
- Registers that have the AUTHSTATUS mnemonic. This is a read-only status register that reflects the status outside of the reset domain of the register.
- Registers that have the LAR mnemonic. These are write-only registers that only have an effect on writes.

All other fields in the management registers are reset to an IMPLEMENTATION DEFINED value which can be UNKNOWN. The registers are in the reset domain specified in the table.

Table K2-7 shows a summary of the management register resets.

Table K2-7 Management register resets

Register	Reset domain	Field	Value	Description
CTIITCTRL EDITCTRL PMITCTRL	IMPLEMENTATION DEFINED	IME	0	Integration mode enable
DBGCLAIMCLR_EL1	Cold reset	CLAIM	0x00	CLAIM tags
CTICLAIMCLR	External debug	CLAIM	0x00000000	
CTILSR ^a EDLSR ^a PMLSR ^a	External debug	SLK	1	Software Lock

a. Only if the OPTIONAL Software Lock is implemented

K2.4.4 About the Peripheral identification scheme

The Peripheral Identification scheme provides the standard information required by all components that conform to the *ARM® Debug Interface Architecture Specification, ADIv5.0 to ADIv5.2*, that implements the CoreSight identification scheme. They identify a peripheral in a particular namespace. For more information, see the *ARM® CoreSight™ Architecture Specification*.

Table K2-8 on page K2-6147 lists the Peripheral ID Registers that make up the Peripheral Identification scheme for each component.

Table K2-8 Peripheral Identification Registers

Register offset	Description	Reference		
		External Debug	CTI	Performance Monitors
0xFD0	Peripheral ID4	EDPIDR4	CTIPIDR4	PMPIDR4
0xFD4	Reserved for Peripheral ID5	-	-	-
0xFD8	Reserved for Peripheral ID6	-	-	-
0xFDC	Reserved for Peripheral ID7	-	-	-
0xFE0	Peripheral ID0	EDPIDR0	CTIPIDR0	PMPIDR0
0xFE4	Peripheral ID1	EDPIDR1	CTIPIDR1	PMPIDR1
0xFE8	Peripheral ID2	EDPIDR2	CTIPIDR2	PMPIDR2
0xFEC	Peripheral ID3	EDPIDR3	CTIPIDR3	PMPIDR3

Figure K2-2 shows the register field allocation scheme for the Peripheral ID Registers.

Figure K2-2 Peripheral ID register format

Software can consider the eight Peripheral ID Registers as defining a single 64-bit Peripheral ID, as shown in Figure K2-3.

Figure K2-3 Mapping between Peripheral ID Registers and a 64-bit Peripheral ID Value

Figure K2-3 shows the fields in the 64-bit Peripheral ID value, and includes the field values for fields that:

- Have fixed values, including the bits that are reserved.
- Have fixed values in an implementation that is designed by ARM.

For more information about the fields and their values see Table K2-9 on page K2-6148.

Figure K2-4 Peripheral ID fields, with values for a implementation designed by ARM

Table K2-9 shows the fields in the Peripheral ID.

Table K2-9 Fields in the Peripheral Identification Registers

Name	Size	Description	Registers
4KB count	4 bits	Log2 of the number of 4KB blocks occupied by the implementation.	EDPIDR4 CTIPIDR4 PMPIDR4
JEP106 code	4-7 bits	Identifies the designer of the implementation. This value consists of: <ul style="list-style-type: none"> A 4-bit continuation code, also described as the bank number. A 7-bit identification code. For implementations designed by ARM, the continuation code is 0x4, indicating bank 5, and the identity code is 0x3B.	EDPIDR1, EDPIDR2, EDPIDR4 CTIPIDR1, CTIPIDR2, CTIPIDR4 PMPIDR1, PMPIDR2, PMPIDR4
RevAnd	4 bits	Manufacturing revision number. Indicates a late modification to the implementation, usually as a result of an <i>Engineering Change Order</i> (ECO). This field starts at 0x0 and is incremented by the integrated circuit manufacturer on metal fixes.	EDPIDR3 CTIPIDR3 PMPIDR3
Customer modified	4 bits	Indicates an endorsed modification to the implementation. If the system designer cannot modify the implementation supplied by the implementation designer then this field is RES0.	EDPIDR3 CTIPIDR3 PMPIDR3
Revision	4 bits	Revision number for the implementation. Starts at 0x0 and increments by 1 at both major and minor revisions.	EDPIDR2 CTIPIDR2 PMPIDR2
Uses JEP106 ID code	1 bit	This bit is set to 1 when a JEP106 identification code is used. This bit must be 1 on all ARMv8 implementations.	EDPIDR2 CTIPIDR2 PMPIDR2
Part number	12 bits	Part number for the implementation. Each organization designing to the ARM Debug architecture specification keeps its own part number list.	EDPIDR0, EDPIDR1 CTIPIDR0, CTIPIDR1 PMPIDR0, PMPIDR1

A component is identified uniquely by the combination of the following fields:

- JEP106 continuation code.
- JEP106 identity code.
- Part number.
- Revision.
- Customer Modified.
- RevAnd.

For components with a *Component class* of 0x9, Debug component, indicated by the Component Identification Registers, multiple components can have the same Part number, provided each component has a different CoreSight *Device type*. However, ARM strongly recommends that each device has a unique Part number. For more information:

- About the Component Identification Registers, see [About the Component Identification scheme on page K2-6149](#).
- About the CoreSight Device type, see [EDDEVTYPE](#), [CTIDEVTYPE](#), or [PMDEVTYPE](#).
- About CoreSight components and their identification, see the *ARM® Debug Interface Architecture Specification*.

Allocating revisions and part numbers

Within the Peripheral Identification registers, the allocation of major and minor revisions, part numbers, and customer-modified fields is IMPLEMENTATION DEFINED, with the following set of restrictions so that:

- The REVISION field must increase monotonically with revisions.

———— **Note** —————

ARM recommends that the REVISION field is updated for each update to the RTL, regardless of whether this is a major or minor update.

- The REVAND field should increase monotonically with revisions.

———— **Note** —————

ARM recommends that the REVAND field is used only for post-release changes. For example, those due to engineering change order (ECO) fixes related to the debug component of the processor.

- The PART field must have a degree of uniqueness:

- Two component designs can have the same part number so long as they are sub-components of the same part and the programmers' model for the part has the means to disambiguate sub-components.
- Otherwise, two component designs must have unique part numbers.

The DEVARCH (if implemented) or DEVTYPE (otherwise) register provides the means to disambiguate sub-components of the Debug Architecture.

A ROM table has no DEVTYPE or DEVARCH register. However, if it is the only CLASS 0x1 component in a processor cluster, it can still be disambiguated.

Multiple instances of the same component design have the same part number.

K2.4.5 About the Component Identification scheme

The Component Identification Registers identify the processor as an ARM Debug Interface v5 component. For more information, see the *ARM® Debug Interface Architecture Specification* and the *ARM® CoreSight™ Architecture Specification*.

The Component Identification Registers occupy the last four words of the 4KB block of debug registers.

Table K2-10 Component Identification Registers

Register offset	Description	External debug	CTI	Performance Monitors
0xFF0	Component ID0	EDCIDR0	CTICIDR0	PMCIDR0
0xFF0	Component ID1	EDCIDR1	CTICIDR1	PMCIDR1
0xFF0	Component ID2	EDCIDR2	CTICIDR2	PMCIDR2
0xFF0	Component ID3	EDCIDR3	CTICIDR3	PMCIDR3

Figure K2-5 shows the register field allocation scheme for the Component ID Registers.

Figure K2-5 Component ID Register format

Software can consider the eight Component ID Registers as defining a single 32-bit Component ID, as shown in Figure K2-6 on page K2-6150.

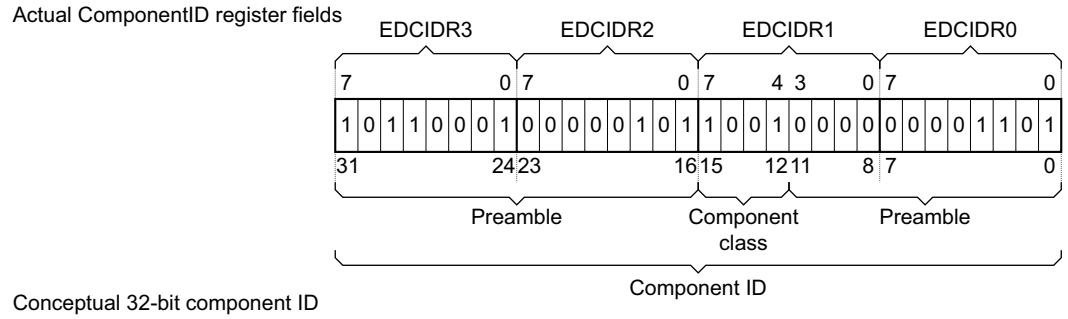

Figure K2-6 Mapping between Component ID Registers and a 32-bit Component ID Value

Appendix K3

Recommendations for Performance Monitors Event Numbers for IMPLEMENTATION DEFINED Events

This appendix describes the ARM recommendations for the use of the IMPLEMENTATION DEFINED event numbers. It contains the following sections:

- *ARM recommendations for IMPLEMENTATION DEFINED event numbers on page K3-6152.*
- *Summary of events for exceptions taken to an Exception level using AArch64 on page K3-6166.*

K3.1 ARM recommendations for IMPLEMENTATION DEFINED event numbers

These are the ARM recommendations for the use of the IMPLEMENTATION DEFINED event numbers. ARM does not define these events as rigorously as those in the architectural and microarchitectural event lists, and an implementation might:

- Modify the definition of an event to better correspond to the implementation.
- Not use some, or many, of these event numbers.

Table K3-1 lists the PMU IMPLEMENTATION DEFINED event numbers in event number order.

Table K3-1 PMU IMPLEMENTATION DEFINED event numbers

Event number	Event mnemonic	Description
0x0040	L1D_CACHE_RD	Attributable Level 1 data cache access, read
0x0041	L1D_CACHE_WR	Attributable Level 1 data cache access, write
0x0042	L1D_CACHE_REFILL_RD ^a	Attributable Level 1 data cache refill, read
0x0043	L1D_CACHE_REFILL_WR ^a	Attributable Level 1 data cache refill, write
0x0044	L1D_CACHE_REFILL_INNER	Attributable Level 1 data cache refill, inner
0x0045	L1D_CACHE_REFILL_OUTER	Attributable Level 1 data cache refill, outer
0x0046	L1D_CACHE_WB_VICTIM	Attributable Level 1 data cache Write-Back, victim
0x0047	L1D_CACHE_WB_CLEAN	Level 1 data cache Write-Back, cleaning and coherency
0x0048	L1D_CACHE_INVAL	Attributable Level 1 data cache invalidate
0x0049-0x004B	-	Reserved
0x004C	L1D_TLB_REFILL_RD ^a	Attributable Level 1 data TLB refill, read
0x004D	L1D_TLB_REFILL_WR ^a	Attributable Level 1 data TLB refill, write
0x004E	L1D_TLB_RD	Attributable Level 1 data or unified TLB access, read
0x004F	L1D_TLB_WR	Attributable Level 1 data or unified TLB access, write
0x0050	L2D_CACHE_RD	Attributable Level 2 data cache access, read
0x0051	L2D_CACHE_WR	Attributable Level 2 data cache access, write
0x0052	L2D_CACHE_REFILL_RD ^a	Attributable Level 2 data cache refill, read
0x0053	L2D_CACHE_REFILL_WR ^a	Attributable Level 2 data cache refill, write
0x0054-0x0055	-	Reserved
0x0056	L2D_CACHE_WB_VICTIM	Attributable Level 2 data cache Write-Back, victim
0x0057	L2D_CACHE_WB_CLEAN	Level 2 data cache Write-Back, cleaning and coherency
0x0058	L2D_CACHE_INVAL	Attributable Level 2 data cache invalidate
0x0059-0x005B	-	Reserved
0x005C	L2D_TLB_REFILL_RD ^a	Attributable Level 2 data or unified TLB refill, read
0x005D	L2D_TLB_REFILL_WR ^a	Attributable Level 2 data or unified TLB refill, write

Table K3-1 PMU IMPLEMENTATION DEFINED event numbers (continued)

Event number	Event mnemonic	Description
0x005E	L2D_TLB_RD	Attributable Level 2 data or unified TLB access, read
0x005F	L2D_TLB_WR	Attributable Level 2 data or unified TLB access, write
0x0060	BUS_ACCESS_RD	Bus access, read
0x0061	BUS_ACCESS_WR	Bus access, write
0x0062	BUS_ACCESS_SHARED	Bus access, Normal, Cacheable, Shareable
0x0063	BUS_ACCESS_NOT_SHARED	Bus access, not Normal, Cacheable, Shareable
0x0064	BUS_ACCESS_NORMAL	Bus access, normal
0x0065	BUS_ACCESS_PERIPH	Bus access, peripheral
0x0066	MEM_ACCESS_RD	Data memory access, read
0x0067	MEM_ACCESS_WR	Data memory access, write
0x0068	UNALIGNED_LD_SPEC	Unaligned access, read
0x0069	UNALIGNED_ST_SPEC	Unaligned access, write
0x006A	UNALIGNED_LDST_SPEC	Unaligned access
0x006B	-	Reserved
0x006C	LDREX_SPEC	Exclusive operation speculatively executed, LDREX or LDX
0x006D	STREX_PASS_SPEC	Exclusive operation speculatively executed, STREX or STX pass
0x006E	STREX_FAIL_SPEC	Exclusive operation speculatively executed, STREX or STX pass
0x006F	STREX_SPEC	Exclusive operation speculatively executed, STREX or STX
0x0070	LD_SPEC	Operation speculatively executed, load
0x0071	ST_SPEC	Operation speculatively executed, store
0x0072	LDST_SPEC	Operation speculatively executed, load or store
0x0073	DP_SPEC	Operation speculatively executed, integer data processing
0x0074	ASE_SPEC	Operation speculatively executed, Advanced SIMD instruction
0x0075	VFP_SPEC	Operation speculatively executed, floating-point instruction
0x0076	PC_WRITE_SPEC	Operation speculatively executed, software change of the PC
0x0077	CRYPTO_SPEC	Operation speculatively executed, Cryptographic instruction
0x0078	BR_IMMED_SPEC	Branch speculatively executed, immediate branch
0x0079	BR_RETURN_SPEC	Branch speculatively executed, procedure return
0x007A	BR_INDIRECT_SPEC	Branch speculatively executed, indirect branch
0x007B	-	Reserved
0x007C	ISB_SPEC	Barrier speculatively executed, ISB
0x007D	DSB_SPEC	Barrier speculatively executed, DSB

Table K3-1 PMU IMPLEMENTATION DEFINED event numbers (continued)

Event number	Event mnemonic	Description
0x007E	DMB_SPEC	Barrier speculatively executed, DMB
0x007F-0x0080	-	Reserved
0x0081	EXC_UNDEF	Exception taken, Other synchronous
0x0082	EXC_SVC	Exception taken, Supervisor Call
0x0083	EXC_PABORT	Exception taken, Instruction Abort
0x0084	EXC_DABORT	Exception taken, Data Abort and SError
0x0085	-	Reserved
0x0086	EXC_IRQ	Exception taken, IRQ
0x0087	EXC_FIQ	Exception taken, FIQ
0x0088	EXC_SMC	Exception taken, Secure Monitor Call
0x0089	-	Reserved
0x008A	EXC_HVC	Exception taken, Hypervisor Call
0x008B	EXC_TRAP_PABORT	Exception taken, Instruction Abort not taken locally ^b
0x008C	EXC_TRAP_DABORT	Exception taken, Data Abort or SError not taken locally ^b
0x008D	EXC_TRAP_OTHER	Exception taken, Other traps not taken locally ^b
0x008E	EXC_TRAP_IRQ	Exception taken, IRQ not taken locally ^b
0x008F	EXC_TRAP_FIQ	Exception taken, FIQ not taken locally ^b
0x0090	RC_LD_SPEC	Release consistency operation speculatively executed, Load-Acquire
0x0091	RC_ST_SPEC	Release consistency operation speculatively executed, Store-Release
0x0092-0x009F	-	Reserved
0x00A0	L3D_CACHE_RD	Attributable Level 3 data or unified cache access, read
0x00A1	L3D_CACHE_WR	Attributable Level 3 data or unified cache access, write
0x00A2	L3D_CACHE_REFILL_RD ^a	Attributable Level 3 data or unified cache refill, read
0x00A3	L3D_CACHE_REFILL_WR ^a	Attributable Level 3 data or unified cache refill, write
0x00A4-0x00A5	-	Reserved
0x00A6	L3D_CACHE_WB_VICTIM	Attributable Level 3 data or unified cache Write-Back, victim
0x00A7	L3D_CACHE_WB_CLEAN	Attributable Level 3 data or unified cache Write-Back, cache clean
0x00A8	L3D_CACHE_INVAL	Attributable Level 3 data or unified cache access, invalidate

a. For more information, see *Relationship between REFILL events and associated access events* on page K3-6165.

b. In these definitions, an exception that is *taken locally* means an exception that is taken to the default Exception level, and is not routed to another Exception level. See *Exception levels* on page D1-1776 for more information.

0x0040, L1D_CACHE_RD, Attributable Level 1 data cache access, read

This event is similar to Level 1 data cache access, [L1D_CACHE](#), but the counter counts only memory-read operations that access at least the Level 1 data or unified cache.

0x0041, L1D_CACHE_WR, Attributable Level 1 data cache access, write

This event is similar to Level 1 data cache access, [L1D_CACHE](#), but the counter counts only memory-write operations that access at least the Level 1 data or unified cache.

The counter counts [DC ZVA](#) as a store instruction.

0x0042, L1D_CACHE_REFILL_RD, Attributable Level 1 data cache refill, read

This event is similar to Level 1 data cache refill, [L1D_CACHE_REFILL](#), but the counter counts only memory-read operations that cause a refill of at least the Level 1 data or unified cache.

See also [Relationship between REFILL events and associated access events](#). on page K3-6165.

0x0043, L1D_CACHE_REFILL_WR, Attributable Level 1 data cache refill, write

This event is similar to Level 1 data cache refill, [L1D_CACHE_REFILL](#), but the counter counts only memory-write operations that cause a refill of at least the Level 1 data or unified cache.

The counter counts [DC ZVA](#) as a store instruction.

See also [Relationship between REFILL events and associated access events](#). on page K3-6165.

0x0044, L1D_CACHE_REFILL_INNER, Attributable Level 1 data cache refill, inner

This event is similar to Level 1 data cache refill, [L1D_CACHE_REFILL](#), but the counter counts only memory-read and memory-write operations that generate refills satisfied by transfer from another cache inside of the immediate cluster.

———— **Note** —————

The boundary between *inner* and *outer* is IMPLEMENTATION DEFINED, and it is not necessarily linked to other similar boundaries, such as the boundary between Inner Cacheable and Outer Cacheable or the boundary between Inner Shareable and Outer Shareable.

0x0045, L1D_CACHE_REFILL_OUTER, Attributable Level 1 data cache refill, outer

This event is similar to Level 1 data cache refill, [L1D_CACHE_REFILL](#), but the counter counts only memory-read and memory-write operations that generate refills satisfied from outside of the immediate cluster.

0x0046, L1D_CACHE_WB_VICTIM, Attributable Level 1 data cache Write-Back, victim

This event is similar to Level 1 data cache Write-Back, [L1D_CACHE_WB](#), but the counter counts only Write-Backs that are a result of the line being allocated for an access made by the PE.

Write-Backs caused by the execution of a cache maintenance instruction are not counted.

It is IMPLEMENTATION DEFINED whether a write of a whole cache line that is not the result of the eviction of a line from the cache is counted. For example, this might occur if the PE detects streaming writes to memory and does not allocate lines to the cache, or as the result of a [DC ZVA](#).

0x0047, L1D_CACHE_WB_CLEAN, Level 1 data cache Write-Back, cleaning and coherency

This event is similar to Attributable Level 1 data cache Write-Back, [L1D_CACHE_WB](#), but the counter counts only Write-Backs that are a result of a coherency operation made by another PE or are caused by the execution of a cache maintenance instruction. Whether Write-Backs caused by the execution of a cache maintenance instruction are counted is IMPLEMENTATION DEFINED.

If a coherency request from a requestor outside the PE results in a Write-Back, it is an Unattributable event.

———— **Note** —————

The transfer of a dirty cache line from the Level 1 data cache of this PE to the Level 1 data cache of another PE due to a hardware coherency operation is not counted unless the dirty cache line is also written back to a Level 2 cache or memory.

0x0048, L1D_CACHE_INVALID, Attributable Level 1 data cache invalidate

The counter counts each invalidation of a cache line in the Level 1 data or unified cache.

The counter does not count events:

- If a cache refill invalidates a line.
- For locally-executed cache maintenance instructions that operate by set/way.

If a coherency request from a requestor outside the PE results in a Write-Back, it is an Unattributable event.

0x004C, L1D_TLB_REFILL_RD, Attributable Level 1 data TLB refill, read

This event is similar to Level 1 data TLB refill, [L1D_TLB_REFILL](#), but the counter counts only memory-read operations that cause a data TLB refill of at least the Level 1 data or unified TLB.

See also [Relationship between REFILL events and associated access events](#). on page K3-6165.

0x004D, L1D_TLB_REFILL_WR, Attributable Level 1 data TLB refill, write

This event is similar to Level 1 data TLB refill, [L1D_TLB_REFILL](#), but the counter counts only memory-write operations that cause a data TLB refill of at least the Level 1 data or unified TLB.

The counter counts [DC ZVA](#) as a store instruction.

See also [Relationship between REFILL events and associated access events](#). on page K3-6165.

0x004E, L1D_TLB_RD, Attributable Level 1 data or unified TLB access, read

This event is similar to Level 1 data or unified TLB access, [L1D_TLB](#), but the counter counts only memory-read operations that cause a TLB access to at least the Level 1 data or unified TLB.

0x004F, L1D_TLB_WR, Attributable Level 1 data or unified TLB access, write

This event is similar to Level 1 data or unified TLB access, [L1D_TLB](#), but the counter counts only memory-write operations that cause a TLB access to at least the Level 1 data or unified TLB.

0x0050, L2D_CACHE_RD, Attributable Level 2 data cache access, read

This event is similar to Attributable Level 2 data cache access, [L2D_CACHE](#), but the counter counts only memory-read operations that access at least the Level 2 data or unified cache.

0x0051, L2D_CACHE_WR, Attributable Level 2 data cache access, write

This event is similar to Attributable Level 2 data cache access, [L2D_CACHE](#), but the counter counts only memory-write operations that access at least the Level 2 data or unified cache.

The counter counts [DC ZVA](#) as a store instruction.

0x0052, L2D_CACHE_REFILL_RD, Attributable Level 2 data cache refill, read

This event is similar to Attributable Level 2 data cache refill, [L2D_CACHE_REFILL](#), but the counter counts only memory-read operations that cause a refill of at least the Level 2 data or unified cache.

See also [Relationship between REFILL events and associated access events](#). on page K3-6165.

0x0053, L2D_CACHE_REFILL_WR, Attributable Level 2 data cache refill, write

This event is similar to Attributable Level 2 data cache refill, [L2D_CACHE_REFILL](#), but the counter counts only memory-write operations that cause a refill of at least the Level 2 data or unified cache.

The counter counts [DC ZVA](#) as a store instruction.

See also [Relationship between REFILL events and associated access events](#). on page K3-6165.

0x0056, L2D_CACHE_WB_VICTIM, Attributable Level 2 data cache Write-Back, victim

This event is similar to Attributable Level 2 data cache Write-Back, [L2D_CACHE_WB](#), but the counter counts only Write-Backs that are a result of the line being allocated for an access made by the PE.

Write-Backs caused by the execution of a cache maintenance instruction are not counted.

It is IMPLEMENTATION DEFINED whether a write of a whole cache line that is not the result of the eviction of a line from the cache is counted. For example, this might occur if the PE detects streaming writes to memory and does not allocate lines to the cache, or as the result of a [DC ZVA](#).

0x0057, L2D_CACHE_WB_CLEAN, Level 2 data cache Write-Back, cleaning and coherency

This event is similar to Attributable Level 2 data cache Write-Back, [L2D_CACHE_WB](#), but the counter counts only Write-Backs that are a result of a coherency operation made by another PE or are caused by the execution of a cache maintenance instruction. Whether Write-Backs caused by the execution of a cache maintenance instruction are counted as IMPLEMENTATION DEFINED.

———— **Note** —————

The transfer of a dirty cache line from the Level 2 data cache of this PE to the Level 2 data cache of another PE due to a hardware coherency operation is not counted unless the dirty cache line is also written back to a Level 3 cache or memory.

—————

If a coherency request from a requestor outside the PE results in a Write-Back, it is an Unattributable event.

0x0058, L2D_CACHE_INVAL, Attributable Level 2 data cache invalidate

The counter counts each invalidation of a cache line in the Level 2 data or unified cache.

The counter does not count events:

- If a cache refill invalidates a line.
- For locally executed cache maintenance instructions that operate by set/way.

———— **Note** —————

Software that uses this event must know whether the Level 2 data cache is shared with other PEs. This event does not follow the general rule of Level 2 data cache events of only counting events that directly affect this PE.

—————

If a coherency request from a requestor outside the PE results in a Write-Back, it is an Unattributable event.

0x005C, L2D_TLB_REFILL_RD, Attributable Level 2 data or unified TLB refill, read

This event is similar to Attributable Level 2 data or unified TLB refill, [L2D_TLB_REFILL](#), but the counter counts only Attributable memory read operations that cause a TLB refill of at least the Level 2 data or unified TLB. See also [Relationship between REFILL events and associated access events](#) on page K3-6165.

0x005D, L2D_TLB_REFILL_WR, Attributable Level 2 data or unified TLB refill, write

This event is similar to Attributable Level 2 data or unified TLB refill, [L2D_TLB_REFILL](#), but the counter counts only Attributable memory write operations that cause a TLB refill of at least the Level 2 data or unified TLB. See also [Relationship between REFILL events and associated access events](#) on page K3-6165.

0x005E, L2D_TLB_RD, Attributable Level 2 data or unified TLB access, read

This event is similar to Attributable Level 2 data or unified TLB access, [L2D_TLB](#), but the counter counts only Attributable memory read operations that cause a TLB access to at least the Level 2 data or unified TLB.

0x005F, L2D_TLB_WR, Attributable Level 2 data or unified TLB access, write

This event is similar to Attributable Level 2 data or unified TLB access, [L2D_TLB](#), but the counter counts only Attributable memory write operations that cause a TLB access to at least the Level 2 data or unified TLB.

0x0060, BUS_ACCESS_RD, Bus access, read

This event is similar to Bus access, [BUS_ACCESS](#), but the counter counts only memory-read operations that access outside the boundary of the PE and its closely-coupled caches.

0x0061, BUS_ACCESS_WR, Bus access, write

This event is similar to Bus access, [BUS_ACCESS](#), but the counter counts only memory-write operations that access outside the boundary of the PE and its closely-coupled caches.

0x0062, BUS_ACCESS_SHARED, Bus access, Normal, Cacheable, Shareable

This event is similar to Bus access, [BUS_ACCESS](#), but the counter counts only memory-read and memory-write operations that make Normal, Cacheable, Shareable accesses outside the boundary of the PE and its closely-coupled caches.

———— **Note** —————

It is IMPLEMENTATION DEFINED how the PE translates the attributes from the translation table entry for a region to the attributes on the bus.

In particular, a region of memory designated as Normal, Cacheable, Inner Shareable, Not Outer Shareable by a translation table entry, might be marked as either shareable or Non-shareable at the boundary of the PE and its closely-coupled caches. This depends on where the IMPLEMENTATION DEFINED boundary lies, between Inner and Outer Shareable.

If the Inner Shareable extends beyond the PE boundary, and the bus indicates the distinction between Inner and Outer Shareable, then either is counted as shareable for the purposes of defining this event.

0x0063, BUS_ACCESS_NOT_SHARED, Bus access, not Normal, Cacheable, Shareable

This event is similar to Bus access, [BUS_ACCESS](#), but the counter counts only memory-read and memory-write operations that make accesses outside the boundary of the PE and its closely-coupled caches that are not Normal, Cacheable, Shareable. For example, the counter counts accesses marked as:

- Normal, Cacheable, Non-shareable.
- Normal, Non-cacheable.
- Device.

———— **Note** —————

It is IMPLEMENTATION DEFINED, how the PE translates the attributes from the translation table entries for a region to the attributes on the bus.

In particular, a region of memory designated as Normal, Cacheable, Inner Shareable, Not Outer Shareable by a translation table entry, might be marked as either shareable or Non-shareable at the boundary of the PE and its closely-coupled caches. This depends on where the IMPLEMENTATION DEFINED boundary lies, between Inner and Outer Shareable.

If the Inner Shareable extends beyond the PE boundary, and the bus indicates the distinction between Inner and Outer Shareable, then either is counted as shareable for the purposes of defining this event.

0x0064, BUS_ACCESS_NORMAL, Bus access, normal

This event is similar to Bus access, [BUS_ACCESS](#), but the counter counts only memory-read and memory-write operations that make Normal accesses outside the boundary of the PE and its closely-coupled caches. For example, the counter counts Normal, Cacheable and Normal, Non-cacheable accesses but does not count Device accesses.

0x0065, BUS_ACCESS_PERIPH, Bus access, peripheral

This event is similar to Bus access, [BUS_ACCESS](#), but the counter counts only memory-read and memory-write operations that make Device accesses outside the boundary of the PE and its closely-coupled caches.

0x0066, MEM_ACCESS_RD, Data memory access, read

This event is similar to Data memory access, [MEM_ACCESS](#), but the counter counts only memory-read operations that the PE made.

0x0067, MEM_ACCESS_WR, Data memory access, write

This event is similar to Data memory access, [MEM_ACCESS](#), but the counter counts only memory-write operations made by the PE.

0x0068, UNALIGNED_LD_SPEC, Unaligned access, read

This event is similar to Data memory access, [MEM_ACCESS](#), but the counter counts only unaligned memory-read operations that the PE made. It also counts unaligned accesses if they are subsequently transposed into multiple aligned accesses.

0x0069, UNALIGNED_ST_SPEC, Unaligned access, write

This event is similar to Data memory access, [MEM_ACCESS](#), but the counter counts only unaligned memory-read operations that the PE made. It also counts unaligned accesses if they are subsequently transposed into multiple aligned accesses.

0x006A, UNALIGNED_LDST_SPEC, Unaligned access

This event is similar to Data memory access, [MEM_ACCESS](#), but the counter counts only unaligned memory-read operations and unaligned memory-write operations that the PE made. It also counts unaligned accesses if they are subsequently transposed into multiple aligned accesses.

0x006C, LDREX_SPEC, Exclusive operation speculatively executed, Load-Exclusive

The counter counts Load-Exclusive instructions speculatively executed.

The definition of speculatively executed is IMPLEMENTATION DEFINED.

0x006D, STREX_PASS_SPEC, Exclusive operation speculatively executed, Store-Exclusive pass

The counter counts Store-Exclusive instructions speculatively executed that completed a write.

The definition of speculatively executed is IMPLEMENTATION DEFINED but must be the same as for the [LDREX_SPEC](#) event.

0x006E, STREX_FAIL_SPEC, Exclusive operation speculatively executed, Store-Exclusive fail

The counter counts Store-Exclusive instructions speculatively executed that fail to complete a write. It is within the IMPLEMENTATION DEFINED definition of speculatively executed whether this includes conditional instructions that fail the condition code check.

The definition of speculatively executed is IMPLEMENTATION DEFINED but must be the same as for the [LDREX_SPEC](#) event.

0x006F, STREX_SPEC, Exclusive operation speculatively executed, Store-Exclusive

The counter counts Store-Exclusive instructions speculatively executed.

The definition of speculatively executed is IMPLEMENTATION DEFINED but it must be the same as for the [LDREX_SPEC](#) event.

ARM recommends that this event is implemented if it is not possible to implement the exclusive operation speculatively executed, Store-Exclusive pass, and exclusive operation speculatively executed, Store-Exclusive fail, events with the same degree of speculation as the [LDREX_SPEC](#) event.

0x0070, LD_SPEC, Operation speculatively executed, load

This event is similar to Operation speculatively executed, [INST_SPEC](#), but the counter counts only memory-reading instructions, as defined by the [LD_RETIRED](#) event.

The definition of speculatively executed is IMPLEMENTATION DEFINED but must be the same as for the [INST_SPEC](#) event.

0x0071, ST_SPEC, Operation speculatively executed, store

This event is similar to Operation speculatively executed, INST_SPEC, but the counter counts only memory-writing instructions, as defined by the ST_RETIRED event.

The counter counts DC ZVA as a store operation.

The definition of speculatively executed is IMPLEMENTATION DEFINED but must be the same as for the INST_SPEC event.

0x0072, LDST_SPEC, Operation speculatively executed, load or store

This event is similar to Operation speculatively executed, INST_SPEC, but the counter counts only memory-reading instructions and memory-writing instructions, as defined by the LD_RETIRED and ST_RETIRED events.

The definition of speculatively executed is IMPLEMENTATION DEFINED but must be the same as for the INST_SPEC event.

0x0073, DP_SPEC, Operation speculatively executed, integer data processing

This event is similar to Operation speculatively executed, INST_SPEC, but counts only integer data-processing instructions. It counts the following operations that operate on the general-purpose registers:

- In AArch64 state, *Data processing - immediate* on page C3-176 and *Data processing - register* on page C3-181.
- In AArch32 state, *Data-processing instructions* on page F1-2812.

This includes MOV and MVN operations.

This event also counts the following miscellaneous instructions:

- In AArch64 state, *System register instructions* on page C3-158, *System instructions* on page C3-158, and *Hint instructions* on page C3-159.
- In AArch32 state, *PSTATE and banked register access instructions* on page F1-2820, *Banked register access instructions* on page F1-2820, *Miscellaneous instructions* on page F1-2825, other than ISB and preloads, and *System register access instructions* on page F1-2828, other than LDC and STC instructions.

If the preload instructions PRFM, PLD, PLDW, and PLI, do not count as memory-reading instructions then they must count as integer data-processing instructions.

If ISBs do not count as software change of the PC then they must count as integer data-processing instructions.

The definition of speculatively executed is IMPLEMENTATION DEFINED, but must be the same as for the INST_SPEC event.

It is IMPLEMENTATION DEFINED whether the following instructions are counted as integer data-processing operations, SIMD operations, or floating-point operations, but ARM recommends that the instructions are all counted as integer data-processing operations:

- For AArch64 state, from the A64 floating-point convert to integer class, operations that move a value between a general-purpose register and a SIMD and floating-point register without type conversion:
 - FMOV (general).
- For AArch64 state, from the SIMD Move group, operations that move a values between a general-purpose register and an element or elements in a SIMD and floating-point register:
 - DUP (general).
 - SMOV.
 - UMOV.
 - INS (general).

- For AArch32 state:
 - VDUP (general-purpose register) and all VMOV instructions that transfer data between a general-purpose register and a SIMD and floating-point register.
 - VMRS.
 - VMSR.

0x0074, ASE_SPEC, Operation speculatively executed, Advanced SIMD

This event is similar to Operation speculatively executed, [INST_SPEC](#), but the counter counts only Advanced SIMD data-processing instructions, see:

- For AArch64 state, the SIMD operations listed in [Data processing - SIMD and floating-point on page C3-189](#).
- For AArch32 state, [Advanced SIMD data-processing instructions on page F1-2832](#).

This includes all operations that operate on the SIMD and floating-point registers, except those that are counted as:

- Integer data-processing operations.
- Floating-point data-processing operations.
- Memory-reading operations.
- Memory-writing operations.
- Cryptographic operations other than PMULL, in AArch64 state.
- VMULL, in AArch32 state.

Advanced SIMD scalar operations are counted as Advanced SIMD operations, including those which operate on floating-point values. In AArch64 state, PMULL, and in AArch32 state, VMULL are counted as Advanced SIMD operations.

The definition of speculatively executed is IMPLEMENTATION DEFINED, but must be the same as for the [INST_SPEC](#) event.

0x0075, VFP_SPEC, Operation speculatively executed, floating-point

This event is similar to Operation speculatively executed, [INST_SPEC](#), but the counter counts only floating-point data-processing instructions, see:

- In AArch64 state, only the scalar floating-point operations listed in [Data processing - SIMD and floating-point on page C3-189](#).

———— **Note** ————

This event does not count the SIMD floating-point operations listed in [Data processing - SIMD and floating-point on page C3-189](#).

- In AArch32 state, [Floating-point data-processing instructions on page F1-2840](#).

This includes all operations that operate on the SIMD and floating-point registers as floating-point values, except for SIMD scalar operations and those that are counted as one of:

- Integer data processing.
- Memory-reading operations.
- Memory-writing operations.

The following instructions that take both an integer register and a floating-point register argument and perform a type conversion (to/from integer or to/from fixed-point), are counted as floating-point data-processing operations:

- In AArch64 state, FCVT{<mode>}, UCVTF, and SCVTF.
- In AArch32 state, VCVT<mode>(floating-point), VCVT, VCVTT, and VCVTB.

The definition of speculatively executed is IMPLEMENTATION DEFINED, but must be the same as for the [INST_SPEC](#) event.

0x0076, PC_WRITE_SPEC, Operation speculatively executed, software change of the PC

This event is similar to Operation speculatively executed, [INST_SPEC](#), but the counter counts only software changes of the PC. Defined by the instruction architecturally executed, condition code check pass, software change of the PC event, see [Common event numbers on page D5-2156](#).

The definition of speculatively executed is IMPLEMENTATION DEFINED but must be the same as for the [INST_SPEC](#) event.

See also [PC_WRITE_RETIRED](#).

0x0077, CRYPTO_SPEC, Operation speculatively executed, Cryptographic instruction

This event is similar to Operation speculatively executed, [INST_SPEC](#), but the counter counts only Cryptographic instructions, except PMULL and VMULL, see [The Cryptographic Extension on page C3-207](#).

The definition of speculatively executed is IMPLEMENTATION DEFINED but must be the same as for the [INST_SPEC](#) event.

0x0078, BR_IMMED_SPEC, Branch speculatively executed, immediate branch

The counter counts immediate branch instructions speculatively executed. Defined by the instruction architecturally executed, immediate branch event, see [Common event numbers on page D5-2156](#).

The definition of speculatively executed is IMPLEMENTATION DEFINED.

See also [BR_IMMED_RETIRED](#).

0x0079, BR_RETURN_SPEC, Branch speculatively executed, procedure return

The counter counts procedure return instructions speculatively executed. Defined by the [BR_RETURN_RETIRED](#) event.

The definition of speculatively executed is IMPLEMENTATION DEFINED.

See also [BR_RETURN_RETIRED](#).

0x007A, BR_INDIRECT_SPEC, Branch speculatively executed, indirect branch

The counter counts indirect branch instructions speculatively executed. This includes software change of the PC other than exception-generating instructions and immediate branch instructions.

The definition of speculatively executed is IMPLEMENTATION DEFINED.

0x007C, ISB_SPEC, Barrier speculatively executed, ISB

The counter counts Instruction Synchronization Barrier instructions speculatively executed, including [CP15ISB](#).

The definition of speculatively executed is IMPLEMENTATION DEFINED.

0x007D, DSB_SPEC, Barrier speculatively executed, DSB

The counter counts data synchronization barrier instructions speculatively executed, including [CP15DSB](#).

The definition of speculatively executed is IMPLEMENTATION DEFINED.

0x007E, DMB_SPEC, Barrier speculatively executed, DMB

The counter counts data memory barrier instructions speculatively executed, including [CP15DSB](#). It does not include the implied barrier operations of load/store operations with release consistency semantics.

The definition of speculatively executed is IMPLEMENTATION DEFINED.

0x0081, EXC_UNDEF, Exception taken, other synchronous

This event is similar to Exception taken, [EXC_TAKEN](#), but the counter counts only synchronous exceptions that are not counted by the other Exception taken events. This event counts only exceptions taken locally.

0x0082, EXC_SVC, Exception taken, Supervisor Call

This event is similar to Exception taken, [EXC_TAKEN](#), but the counter counts only Supervisor Call exceptions. This event counts only exceptions taken locally.

0x0083, EXC_PABORT, Exception taken, Instruction Abort

This event is similar to Exception taken, [EXC_TAKEN](#), but the counter counts only Instruction Abort exceptions. This event counts only exceptions taken locally.

0x0084, EXC_DABORT, Exception taken, Data Abort or SError

This event is similar to Exception taken, [EXC_TAKEN](#), but the counter counts only Data Abort or SError interrupt exceptions. The counter counts only exceptions taken locally.

0x0086, EXC_IRQ, Exception taken, IRQ

This event is similar to Exception taken, [EXC_TAKEN](#), but the counter counts only IRQ exceptions. The counter counts only exceptions taken locally, including Virtual IRQ exceptions.

0x0087, EXC_FIQ, Exception taken, FIQ

This event is similar to Exception taken, [EXC_TAKEN](#), but the counter counts only FIQ exceptions. The counter counts only exceptions taken locally, including Virtual FIQ exceptions.

0x0088, EXC_SMC, Exception taken, Secure Monitor Call

This event is similar to Exception taken, [EXC_TAKEN](#), but the counter counts only Secure Monitor Call exceptions. The counter does not increment on SMC instructions trapped as a Hyp Trap exception.

0x008A, EXC_HVC, Exception taken, Hypervisor Call

This event is similar to Exception taken, [EXC_TAKEN](#), but the counter counts only Hypervisor Call exceptions. The counter counts for both Hypervisor Call exceptions taken locally in the hypervisor and those taken as an exception from Non-secure EL1.

0x008B, EXC_TRAP_PABORT, Exception taken, Instruction Abort not taken locally

This event is similar to Exception taken, [EXC_TAKEN](#), but the counter counts only Instruction Abort exceptions not taken locally.

0x008C, EXC_TRAP_DABORT, Exception taken, Data Abort or SError not taken locally

This event is similar to Exception taken, [EXC_TAKEN](#), but the counter counts only Data Abort or SError interrupt exceptions not taken locally.

0x008D, EXC_TRAP_OTHER, Exception taken, other traps not taken locally

This event is similar to Exception taken, [EXC_TAKEN](#), but the counter counts only those traps that are not counted as:

- Exception taken, Hypervisor Call.
- Exception taken, Instruction Abort not taken locally.
- Exception taken, Data Abort or SError not taken locally.
- Exception taken, IRQ not taken locally.
- Exception taken, FIQ not taken locally.

0x008E, EXC_TRAP_IRQ, Exception taken, IRQ not taken locally

This event is similar to Exception taken, [EXC_TAKEN](#), but the counter counts only IRQ exceptions not taken locally.

0x008F, EXC_TRAP_FIQ, Exception taken, FIQ not taken locally

This event is similar to Exception taken, [EXC_TAKEN](#), but the counter counts only FIQ exceptions not taken locally.

0x0090, RC_LD_SPEC, Release consistency operation speculatively executed, Load-Acquire

The counter counts Load-Acquire operations that are speculatively executed. The definition of speculatively executed is IMPLEMENTATION DEFINED.

0x0091, RC_ST_SPEC, Release consistency operation speculatively executed, Store-Release

The counter counts Store-Release operations that are speculatively executed. The definition of speculatively executed is IMPLEMENTATION DEFINED.

0x00A0, L3D_CACHE_RD, Attributable Level 3 data or unified cache access, read

This event is similar to Attributable Level 3 data or unified cache access, [L3D_CACHE](#), but the counter counts only attributable memory read operations that cause a cache access to at least the Level 3 data or unified cache.

0x00A1, L3D_CACHE_WR, Attributable Level 3 data or unified cache access, write

This event is similar to Attributable Level 3 data or unified cache access, [L3D_CACHE](#), but the counter counts only attributable memory write operations that cause a cache access to at least the Level 3 data or unified cache.

0x00A2, L3D_CACHE_REFILL_RD, Attributable Level 3 data or unified cache refill, read

This event is similar to Attributable Level 3 data or unified cache refill, [L3D_CACHE_REFILL](#), but the counter counts only attributable memory read operations that cause a refill of at least the Level 3 data or unified cache from outside the Level 3 cache. See also [Relationship between REFILL events and associated access events](#). on page K3-6165

0x00A3, L3D_CACHE_REFILL_WR, Attributable Level 3 data or unified cache refill, write

This event is similar to Attributable Level 3 data or unified cache refill, [L3D_CACHE_REFILL](#), but the counter counts only attributable memory write operations that cause a refill of at least the Level 3 data or unified cache from outside the Level 3 cache. See also [Relationship between REFILL events and associated access events](#). on page K3-6165

0x00A6, L3D_CACHE_WB_VICTIM, Attributable Level 3 data or unified cache Write-Back, victim

This event is similar to Attributable Level 3 data cache Write-Back, [L3D_CACHE_WB](#), but the counter counts only Write-Backs that are a result of the line being allocated for an access made by the PE.

Write-Backs caused by the execution of a cache maintenance instruction are not counted.

It is IMPLEMENTATION DEFINED whether a write of a whole cache line that is not the result of the eviction of a line from the cache is counted. For example, this might occur if the PE detects streaming writes to memory and does not allocate lines to the cache, or as the result of a [DC ZVA](#).

0x00A7, L3D_CACHE_WB_CLEAN, Level 3 data or unified cache Write-Back, cache clean

This event is similar to Attributable Level 3 data cache Write-Back, [L3D_CACHE_WB](#), but the counter counts only Write-Backs that are a result of a coherency operation made by another PE or are caused by the execution of a cache maintenance instruction. Whether Write-Backs that are caused by the execution of a cache maintenance instruction are counted is IMPLEMENTATION DEFINED.

———— **Note** —————

The transfer of a dirty cache line from the Level 3 data cache of this PE to the Level 3 data cache of another PE due to a hardware coherency operation is not counted unless the dirty cache line is also written back to a Level 3 cache or memory.

If a coherency request from a requestor outside the PE results in a Write-Back, it is an Unattributable event.

0x00A8, L3D_CACHE_INVALID, Attributable Level 3 data or unified cache access, invalidate

The counter counts each invalidation of a cache line in the Level 3 data or unified cache.

The counter does not count events:

- If a cache refill invalidates a line.
- For locally-executed cache maintenance instructions that operate by set/way.

———— **Note** —————

Software that uses this event must know whether the Level 3 data cache is shared with other PEs. This event does not follow the general rule of Level 3 data cache events of only counting Attributable events.

K3.1.1 Relationship between REFILL events and associated access events.

CACHE_REFILL and TLB_REFILL events count the refills for accesses that are counted by the corresponding CACHE or TLB event. Table K3-2 shows this correspondence.

Table K3-2 Relationship between REFILL events and associated access events

REFILL event	Access event	Ratio REFILL/Access
0x0042 L1D_CACHE_REFILL_RD	0x0040 L1D_CACHE_RD	Attributable Level 1 cache refill rate, read
0x0043 L1D_CACHE_REFILL_WR	0x0041 L1D_CACHE_WR	Attributable Level 1 cache refill rate, write
0x004C L1D_TLB_REFILL_RD	0x004E L1D_TLB_RD	Attributable Level 1 TLB refill rate, read
0x004D L1D_TLB_REFILL_WR	0x004F L1D_TLB_WR	Attributable Level 1 TLB refill rate, write
0x0052 L2D_CACHE_REFILL_RD	0x0050 L2D_CACHE_RD	Attributable Level 2 data cache refill rate, read
0x0053 L2D_CACHE_REFILL_WR	0x0051 L2D_CACHE_WR	Attributable Level 2 data cache refill rate, write
0x005C L2D_TLB_REFILL_RD	0x005E L2D_TLB_RD	Attributable Level 2 data TLB refill rate, read
0x005D L2D_TLB_REFILL_WR	0x005F L2D_TLB_WR	Attributable Level 2 data TLB refill rate, write
0x00A2 L3D_CACHE_REFILL_RD	0x00A0 L3D_CACHE_RD	Attributable Level 3 data cache refill rate, read
0x00A3 L3D_CACHE_REFILL_WR	0x00A1 L3D_CACHE_WR	Attributable Level 3 data cache refill rate, write

K3.2 Summary of events for exceptions taken to an Exception level using AArch64

Table K3-3 shows the events for exceptions taken to an Exception level using AArch64.

Table K3-3 Events for exceptions taken to an Exception level using AArch64

ESR.EC	Description	Event number and classification for exception taken to	
		EL1, or the current Exception level	EL2 or EL3, from below
0x00	Unknown or uncategorized	0x0081, Other synchronous	0x008D, Other traps not taken locally
0x01	WFE/WFI traps	0x0081, Other synchronous	0x008D, Other traps not taken locally
0x03	AArch32 MCR/MRC traps on (coproc==0b1111) accesses	0x0081, Other synchronous	0x008D, Other traps not taken locally
0x04	AArch32 MCRR/MRRC traps on (coproc==0b1111) accesses	0x0081, Other synchronous	0x008D, Other traps not taken locally
0x05	AArch32 MCR/MRC traps on (coproc==0b1110) accesses	0x0081, Other synchronous	0x008D, Other traps not taken locally
0x06	AArch32 LDC/STC traps on (coproc==0b1110) accesses	0x0081, Other synchronous	0x008D, Other traps not taken locally
0x07	Advanced SIMD or FP traps	0x0081, Other synchronous	0x008D, Other traps not taken locally

0x12	AArch32 HVC that is not disabled	-	0x008A, Hypervisor Call
0x13	AArch32 SMC that is not disabled	to EL2 -	0x008D, Other traps not taken locally
		to EL3 -	0x0088, Secure Monitor Call
0x15	AArch64 SVC	0x0082, Supervisor Call	0x008D, Other traps not taken locally
0x16	AArch64 HVC that is not disabled	0x008A, Hypervisor Call	0x008A, Hypervisor Call
0x17	AArch64 SMC that is not disabled	to EL2 -	0x008D, Other traps not taken locally
		to EL3 0x0088, Secure Monitor Call	0x0088, Secure Monitor Call
0x18	AArch64 MSR, MRS and system instruction traps	0x0081, Other synchronous	0x008D, Other traps not taken locally
0x20	Instruction Abort from below	0x0083, Instruction Abort	0x008B, Instruction Abort not taken locally
0x21	Instruction Abort from current Exception level	0x0083, Instruction Abort	-
0x22	PC alignment	0x0083, Instruction Abort	0x008B, Instruction Abort not taken locally

Table K3-3 Events for exceptions taken to an Exception level using AArch64 (continued)

ESR.EC	Description	Event number and classification for exception taken to	
		EL1, or the current Exception level	EL2 or EL3, from below
0x24	Data Abort from below	0x0084, Data Abort or SError	0x008C, Data Abort or SError not taken locally
0x25	Data Abort from current Exception level	0x0084, Data Abort or SError	-
0x26	SP alignment fault exception	0x0084, Data Abort or SError	0x008C, Data Abort or SError not taken locally
0x28	AArch32 FP exception	0x0081, Other synchronous	0x008D, Other traps not taken locally
0x2C	AArch64 FP exception	0x0081, Other synchronous	0x008D, Other traps not taken locally
0x2F	SError interrupt	0x0084, Data Abort or SError	0x008C, Data Abort or SError not taken locally
0x30	Breakpoint from below	0x0083, Instruction Abort	0x008B, Instruction Abort not taken locally
0x31	Breakpoint from current Exception level	0x0083, Instruction Abort	-
0x32	Software step from below	0x0083, Instruction Abort	0x008B, Instruction Abort not taken locally
0x33	Software step from current Exception level	0x0083, Instruction Abort	-
0x34	Watchpoint from below	0x0084, Data Abort or SError	0x008C, Data Abort or SError not taken locally
0x35	Watchpoint from current Exception level	0x0084, Data Abort or SError	-
0x38	AArch32 BKPT instruction	0x0083, Instruction Abort	0x008B, Instruction Abort not taken locally
0x3A	AArch32 Vector Catch debug event	0x0083, Instruction Abort	0x008B, Instruction Abort not taken locally
0x3C	AArch64 BRK instruction	0x0083, Instruction Abort	0x008B, Instruction Abort not taken locally
-	IRQ interrupt	0x0086, IRQ	0x008E, IRQ not taken locally
-	FIQ interrupt	0x0087, FIQ	0x008F, FIQ not taken locally

———— **Note** ————

In these definitions, an exception that is *taken locally* means an exception that is taken to the default Exception level, and is not routed to another Exception level. See [Exception levels on page D1-1776](#) for more information.

Appendix K4

Recommendations for reporting memory attributes on an interconnect

This appendix describes the ARM recommendations for reporting the memory attributes that are assigned by the PE. It contains the following section:

- [ARM recommendations for reporting memory attributes on an interconnect on page K4-6170.](#)

K4.1 ARM recommendations for reporting memory attributes on an interconnect

The ARM architecture defines the architectural interface between software and the PE hardware. This means the mechanisms by which different memory type and Cacheability attributes are presented on an interface to an interconnect fabric such as AMBA® AXI are, strictly, outside the scope of the architecture. This appendix describes an approach for the interface between a PE implementation and an interconnect fabric that ARM strongly recommends, but these recommendations do not form part of the ARMv8 architecture.

K4.1.1 Effect of microarchitectural choices on memory attributes

Implementations of the ARM architecture permit considerable variability in the presentation of memory attributes on the interconnect fabric, particularly in cases where the PE implementation does not provide optimized support for a memory type. For example, an implementation might treat Write-Through locations as Non-cacheable at some level of cache, because functionally this is consistent with the definition of Write-Through, but for the particular implementation the performance trade-off does not merit the hardware directly providing Write-Through capability. However, in such implementations, the assigned memory attributes are not changed by the microarchitectural choices. The microarchitecture simply implements different ways of handling some memory attributes.

Therefore, ARM strongly recommended that where any or all of the following memory attributes are presented on the interface between a PE and an interconnect fabric, the attributes that are presented are completely consistent with the attributes defined by the translation system:

- The memory type, Normal or Device.
- The Early write acknowledgement attribute.
- The ordering requirements.
- The Shareability.
- The Cacheability, including where practicable, the allocation hints.

Effect when memory accesses are forced to be Non-cacheable

ARM also strongly recommends that the effects of forcing accesses to Normal memory to be Non-cacheable, as described in [Enabling and disabling the caching of memory accesses on page D3-1978](#) for AArch64 and in [Enabling and disabling the caching of memory accesses in AArch32 state on page G3-4529](#) for AArch32, are reflected on the interconnect by the memory type and attributes used for memory transactions generated while the cache is disabled.

Appendix K5

Legacy Instruction Syntax for AArch32 Instruction Sets

This appendix describes the legacy instruction syntax in the ARM instruction sets, and their *Unified Assembler Language* (UAL) equivalents. It contains the following section:

- [Legacy Instruction Syntax on page K5-6172.](#)

K5.1 Legacy Instruction Syntax

Early versions of the ARM Architecture defined an assembly language for A32 (ARM) instructions, and a separate assembly language for T32 (Thumb) instructions. UAL is based on the A32 assembly language, with some changes to the instruction syntax. The appendix describes those changes. The pre-UAL mnemonics are compatible with UAL, and might be supported by an assembler.

The original T32 assembly language is not compatible with UAL, and is not described in the manual.

K5.1.1 Pre-UAL instruction syntax for the A32 base instructions

Table K5-1 lists the syntax for the A32 base instructions that have changed after UAL was introduced.

Table K5-1 Pre-UAL instruction syntax for the A32 base instructions

Pre-UAL syntax	UAL equivalent	See
ADC<c>S	ADCS<c>	<i>ADC, ADCS (immediate)</i> on page F5-3005, <i>ADC, ADCS (register)</i> on page F5-3007, <i>ADC, ADCS (register-shifted register)</i> on page F5-3011

K5.1.3 FCONST

The syntax of FCONST is

FCONST<dest>{<c>} <Fd>, #<imm8>

where:

<dest> Specifies the destination data type. It must be one of:

S . Single-precision floating-point.

D . Double-precision floating-point.

<c> This is an optional field. It specifies the condition under which the instruction is executed. See [Conditional execution on page F2-2849](#) for the range of available conditions and their encoding. If <c> is omitted, it defaults to *always* (AL).

<Fd> Specifies the destination register. It must be one of:

<Dd> 64-bit name of the SIMD&FP destination register.

<Sd> 32-bit name of the SMID&FP destination register.

<imm8> Specifies the immediate value used to generate the floating-point constant.

FCONSTD{<c>} <Dd>, #<imm8> maps to VMOV.F64 <Dd>, #<fpimm>

FCONSTS{<c>} <Sd>, #<imm8> maps to VMOV.F32 <Sd>, #<fpimm>

Appendix K6

Address translation examples

This appendix gives examples of address translations using the translation regimes described in [Chapter D4 The AArch64 Virtual Memory System Architecture](#) and [Chapter G4 The AArch32 Virtual Memory System Architecture](#). It contains the following sections:

- [AArch64 Address translation examples](#) on page K6-6180.
- [AArch32 Address translation examples](#) on page K6-6193.

———— **Note** —————

This chapter gives examples of translation table lookups for the ARMv8 address translation stages. It does not define any part of the address translation mechanism. If any information in this appendix appears to contradict the information in [Chapter D4 The AArch64 Virtual Memory System Architecture](#) or [Chapter G4 The AArch32 Virtual Memory System Architecture](#) then the information in [Chapter D4](#) or [Chapter G4](#) must be taken as the definition of the required behavior.

K6.1 AArch64 Address translation examples

Figure D4-1 on page D4-2009 shows the VMSAv8 address translation stages that are controlled by an Exception level that is using AArch64. *The VMSAv8-64 address translation system on page D4-2008* describes the VMSAv8-64 address translation scheme. This section gives examples of the use of that scheme, for common translation requirements.

System registers relevant to MMU operation on page D4-2014 specifies the relevant registers, including the TCR_ELx and TTBR_ELx, or TTBR_ELxs, for each stage of address translation.

For any stage of translation, a TCR_ELx.TnSZ field indicates the supported input address size. For a stage of address translation controlled from an Exception level using AArch64, the supported input address size is $2^{(64-TnSZ)}$.

This section describes:

- Performing the initial lookup, for an address for which the initial lookup is either:
 - At the highest lookup level used for the appropriate translation granule size.
 - Because of the concatenation of translation tables at the initial lookup level, one level down from the highest level used for the translation granule size.

These descriptions take account of the following cases:

- The IA size is smaller than the largest size for the translation level, see *Reduced IA width on page D4-2025*.
- For a stage 2 translation, translation tables are concatenated, to move the initial lookup level down by one level, see *Concatenated translation tables on page D4-2025*.

For examples of performing the initial lookup, see *Examples of performing the initial lookup*.

- The full translation flow for resolving a page of memory. These examples describe resolving the largest IA size supported by the initial lookup level. For these examples, see *Full translation flows for VMSAv8-64 address translation on page K6-6187*.

K6.1.1 Examples of performing the initial lookup

The address ranges used for the initial translation table lookup depend on the translation granule, as described in:

- *Performing the initial lookup using the 4KB translation granule*.
- *Performing the initial lookup using the 16KB granule on page K6-6183*.
- *Performing the initial lookup using the 64KB translation granule on page K6-6185*.

Performing the initial lookup using the 4KB translation granule

This subsection describes examples of the initial lookup when using the 4KB translation granule that [Table D4-13 on page D4-2031](#) shows as starting at level 0 or at level 1. It includes those stage 2 translations where concatenation of translation tables is required for the lookup to start at level 1. This means that it gives specific examples of the mechanisms described in *The VMSAv8-64 address translation system on page D4-2008*.

————— Note —————

For stage 2 translations, the same principles apply to an initial lookup that [Table D4-13 on page D4-2031](#) shows as starting at level 1. In this case, for some IA sizes concatenation of translation tables means the lookup can, instead, start at level 2.

The following subsections describe these examples of the initial lookup:

- *Initial lookup at level 0, 4KB translation granule on page K6-6181*.
- *Initial lookup at level 1, 4KB translation granule on page K6-6181*.

In all cases, for a stage 2 translation, the VTCR_EL2.SL0 field must indicate the required initial lookup level, and this level must be consistent with the value of the VTCR_EL2.T0SZ field, see *Overview of stage 2 translations, 4KB granule on page D4-2031*.

Initial lookup at level 0, 4KB translation granule

This subsection describes initial lookups with an input address width of $(n+1)$ bits, meaning the input address is $IA[n:0]$. As Table D4-13 on page D4-2031 shows, a stage 1 or stage 2 initial lookup at level 0 is required when $39 \leq n \leq 47$. For these lookups:

- $TTBR_ELx[47:(n-35)]$ specify the translation table base address.
- Bits $[n:39]$ of the input address are bits $[(n-36):3]$ of the descriptor offset in the translation table.

———— **Note** ————

This means that, when the input address width is less than 48 bits

- The size of the translation table is reduced.
- More low-order bits of the $TTBR_ELx$ are required to specify the translation table base address.
- Fewer input address bit are used to specify the descriptor offset in the translation table.

For example, if the input address width is 46 bits:

- The translation table size is 1KB,
- $TTBR_ELx$ bits $[47:10]$ specify the translation table base address.
- Input address bits $[45:39]$ specify bits $[9:3]$ of the descriptor offset.

Figure K6-1 shows this lookup.

Supported input address range is $IA[y:0]$, $4 \leq x \leq 12$, $y = x + 35$. When y is 47 the field marked † is absent.

† For a Non-secure EL1&0 stage 1 translation, the IPA of the descriptor. Otherwise, the PA of the descriptor.

* Field has additional properties to the default RES0 definition, see the register description for more information.

Figure K6-1 Initial lookup for VMSAv8-64 using the 4KB granule, starting at level 0

Initial lookup at level 1, 4KB translation granule

This subsection describes initial lookups with an input address width of $(n+1)$ bits, meaning the input address is $IA[n:0]$.

For a stage 1 or stage 2 initial lookup at level 1, without use of concatenated translation tables

As Table D4-13 on page D4-2031 shows, this applies to $IA[n:0]$, where $30 \leq n \leq 38$. For these lookups:

- There is a single translation table at this level.
- $TTBR_ELx[47:(n-26)]$ specify the translation table base address.
- Bits $[n:30]$ of the input address are bits $[(n-27):3]$ of the descriptor offset in the translation table.

Figure K6-2 on page K6-6182 shows this lookup.

Supported input address range is $IA[y:0]$, $4 \leq x \leq 12$, $y = x + 26$.

[†] For a Non-secure EL1&0 stage 1 translation, the IPA of the descriptor. Otherwise, the PA of the descriptor.

* Field has additional properties to the default RES0 definition, see the register description for more information.

Figure K6-2 Initial lookup for VMSAv8-64 using the 4KB granule, starting at level 1, without concatenation

For a stage 2 initial lookup at level 1, with concatenated translation tables

As Table D4-13 on page D4-2031 shows, this applies to $IA[n:0]$, where $39 \leq n \leq 42$. For these lookups:

- There are $2^{(n-38)}$ concatenated translation tables at this level.
- These concatenated translation tables must be aligned to $2^{(n-38)} \times 4\text{KB}$. This means $TTBR_ELx[(n-27):12]$ must be zero.
- $TTBR_ELx[47:(n-26)]$ specify the base address of the block of concatenated translation tables.
- Bits $[n:30]$ of the input address are bits $[(n-27):3]$ of the descriptor offset from the base address of the block of concatenated translation tables.

Figure K6-3 shows this lookup.

Supported input address range is $IPA[y:0]$, $4 \leq x \leq 16$, $y = x + 26$. The field marked ‡ must be zero.

* Field has additional properties to the default RES0 definition, see the register description for more information.

Figure K6-3 Initial lookup for VMSAv8-64 using the 4KB granule, starting at level 1, with concatenation

Performing the initial lookup using the 16KB granule

This subsection describes examples of the initial lookup when using the 16KB translation granule that Table D4-16 on page D4-2035 shows as starting at level 0 or at level 1. It includes those stage 2 translations where concatenation of translation tables is required for the lookup to start at level 1. This means that it gives specific examples of the mechanisms described in *The VMSAv8-64 address translation system* on page D4-2008.

———— Note ————

For stage 2 translations, the same principles apply to an initial lookup that Table D4-16 on page D4-2035 shows as starting at level 1. In this case, for some IA sizes concatenation of translation tables means the lookup can, instead, start at level 2.

The following subsections describe these examples of the initial lookup:

- [Initial lookup at level 0, 16KB translation granule.](#)
- [Initial lookup at level 1, 16KB translation granule on page K6-6184.](#)

In all cases, for a stage 2 translation, the `VTCCR_EL2.SL0` field must indicate the required initial lookup level, and this level must be consistent with the value of the `VTCCR_EL2.T0SZ` field, see [Overview of stage 2 translations, 16KB granule on page D4-2035.](#)

Initial lookup at level 0, 16KB translation granule

This subsection describes initial lookups with an input address width of $(n+1)$ bits, meaning the input address is `IA[n:0]`. As Table D4-15 on page D4-2034 shows, the only case where an address translation using the 16KB granule starts at level 0 is a stage 1 translation of a 48-bit input address, `IA[47:0]`. For this lookup:

- The required translation table has only two entries, meaning its size is 16 bytes, and it must be aligned to 16 bytes.
- `TTBR_ELx[47:4]` specify the translation table base address.
- Bit[47] of the input address is bits[3] of the descriptor offset in the translation table.

Figure K6-4 shows this lookup.

Supported input address range is `IA[47:0]`. The field marked † is `RES0*`.

† For a Non-secure EL1&0 stage 1 translation, the IPA of the descriptor. Otherwise, the PA of the descriptor.

* Field has additional properties to the default `RES0` definition, see the register description for more information.

Figure K6-4 Initial lookup for VMSAv8-64 using the 16KB granule, starting at level 0

Initial lookup at level 1, 16KB translation granule

This subsection describes initial lookups with an input address width of $(n+1)$ bits, meaning the input address is $IA[n:0]$.

For a stage 1 or stage 2 initial lookup at level 1, without use of concatenated translation tables

As Table D4-16 on page D4-2035 shows, this applies to $IA[n:0]$, where $36 \leq n \leq 46$. For these lookups:

- There is a single translation table at this level.
- $TTBR_ELx[47:(n-32)]$ specify the translation table base address.
- Bits $[n:36]$ of the input address are bits $[(n-33):3]$ of the descriptor offset in the translation table.

Figure K6-5 shows this lookup.

Supported input address range is $IA[y:0]$, $4 \leq x \leq 14$, $y = x + 32$.

† For a Non-secure EL1&0 stage 1 translation, the IPA of the descriptor. Otherwise, the PA of the descriptor.

* Field has additional properties to the default RES0 definition, see the register description for more information.

Figure K6-5 Initial lookup for VMSAv8-64 using the 16KB granule, starting at level 1, without concatenation

For a stage 2 initial lookup at level 1, with concatenated translation tables

As Table D4-16 on page D4-2035 shows, the only case where an address translation using the 16KB granule starts at level 1 because of concatenation of translation tables is a stage 2 translation of a 48-bit input address, $IA[47:0]$. For this lookup:

- There are two concatenated translation tables at this level.
- These concatenated translation tables must be aligned to $2 \times 16KB$. This means $TTBR_ELx[14]$ must be zero.
- $TTBR_ELx[47:15]$ specify the base address of the block of two concatenated translation tables.
- Bits $[47:36]$ of the input address are bits $[14:3]$ of the descriptor offset from the base address of the block of concatenated translation tables.

Figure K6-6 on page K6-6185 shows this lookup.

Supported input address range is IPA[47:0]. The bit marked ‡ must be zero.

* Field has additional properties to the default RES0 definition, see the register description for more information.

Figure K6-6 Initial lookup for VMSAv8-64 using the 16KB granule, starting at level 1, with concatenation

Performing the initial lookup using the 64KB translation granule

This subsection describes examples of the initial lookup when using the 64KB translation granule that [Table D4-19 on page D4-2039](#) shows as starting at level 1 or at level 2. It includes those stage 2 translations where concatenation of translation tables is required for the lookup to start at level 2. This means that it gives specific examples of the mechanisms described in *The VMSAv8-64 address translation system on page D4-2008*.

Note

For stage 2 translations, the same principles apply to an initial lookup that [Table D4-19 on page D4-2039](#) shows as starting at level 2. In this case, for some IA sizes concatenation of translation tables means the lookup can, instead, start at level 3.

The following subsections describe these examples of the initial lookup:

- [Initial lookup at level 1, 64KB translation granule.](#)
- [Initial lookup at level 2, 64KB translation granule on page K6-6186.](#)

In all cases, for a stage 2 translation, the `VTCR_EL2.SL0` field must indicate the required initial lookup level, and this level must be consistent with the value of the `VTCR_EL2.T0SZ` field, see *Overview of stage 2 translations, 64KB granule on page D4-2039*.

Initial lookup at level 1, 64KB translation granule

This subsection describes initial lookups with an input address width of $(n+1)$ bits, meaning the input address is `IA[n:0]`. As [Table D4-19 on page D4-2039](#) shows, a stage 1 or stage 2 initial lookup at level 1 is required when $42 \leq n \leq 47$. For these lookups:

- The size of the translation table is $2^{(n-39)}$ bytes. This means the size of the translation table, at this level, is always less than the granule size. The address of this translation table must align to the size of the table.
- Bits `[n:42]` of the input address are bits `[(n-39):3]` of the descriptor offset in the translation table.
- Bits `[47:(n-38)]` of the `TTBR_ELx` specify the translation table base address.

[Figure K6-7 on page K6-6186](#) shows this lookup.

Supported input address range is $IA[y:0]$, $4 \leq x \leq 9$, $y = x + 38$. When y is 47 the field marked ‡ is absent.
 † For a Non-secure EL1&0 stage 1 translation, the IPA of the descriptor. Otherwise, the PA of the descriptor.
 * Field has additional properties to the default RES0 definition, see the register description for more information.

Figure K6-7 Initial lookup for VMSAv8-64 using the 64KB granule, starting at level 1

Initial lookup at level 2, 64KB translation granule

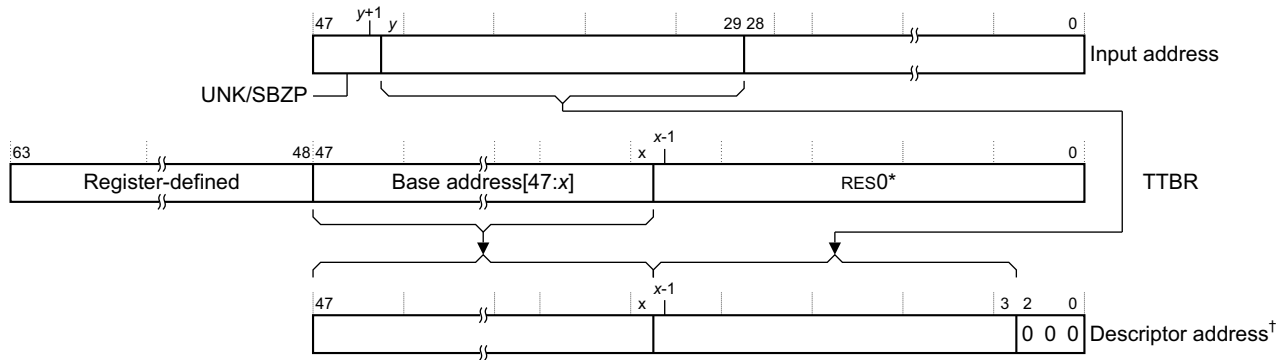

This subsection describes initial lookups with an input address width of $(n+1)$ bits, meaning the input address is $IA[n:0]$.

For a stage 1 or stage 2 initial lookup at level 2, without the use of concatenated translation tables

As Table D4-19 on page D4-2039 shows, this applies to $IA[n:0]$, where $29 \leq n \leq 41$. For these lookups:

- There is a single translation table at this level.
- $TTBR_ELx[47:(n-25)]$ of the specify the translation table base address.
- Bits $[n:29]$ of the input address are bits $[(n-26):3]$ of the descriptor offset in the translation table.

Figure K6-8 shows this lookup.

Supported input address range is $IA[y:0]$. $4 \leq x \leq 16$, $y = x + 25$.
 † For a Non-secure EL1&0 stage 1 translation, the IPA of the descriptor. Otherwise, the PA of the descriptor.
 * Field has additional properties to the default RES0 definition, see the register description for more information.

Figure K6-8 Initial lookup for VMSAv8-64 using the 64KB granule, starting at level 2, without concatenation

For a stage 2 initial lookup at level 2, with concatenated translation tables

As Table D4-19 on page D4-2039 shows, this applies to IA[n:0], where $42 \leq n \leq 45$. For these lookups:

- There are $2^{(m-41)}$ concatenated translation tables at this level.
- These concatenated translation tables must be aligned to $2^{(m-41)} \times 64\text{KB}$. This means $\text{TTBR_ELx}[(n-26):16]$ must be zero.
- $\text{TTBR_ELx}[47:(n-25)]$ specify the base address of the block of translation tables.
- Bits[n:42] of the input address are bits[(n-26):16] of the descriptor offset from the base address of the block of translation tables.

Figure K6-9 shows this lookup.

Supported input address range is $\text{IPA}[y:0]$, $4 \leq x \leq 20$, $y = x + 25$.

* Field has additional properties to the default RES0 definition, see the register description for more information.

Figure K6-9 Initial lookup for VMSAv8-64 using the 64KB granule, starting at level 2, with concatenation

K6.1.2 Full translation flows for VMSAv8-64 address translation

In a translation table walk, only the first lookup uses the translation table base address from the appropriate TTBR_ELx . Subsequent lookups use a combination of address information from:

- The table descriptor read in the previous lookup.
- The input address.

This section describes example full translation flows, from the initial lookup to the address of a memory page. The example flows:

- Resolve the maximum-sized IA range supported by the initial lookup level.
- Do not have any concatenation of translation tables.
- Cover only the 4KB and the 64KB translation granules.

Examples of performing the initial lookup on page K6-6180 described how either reducing the IA range or concatenating translation tables affects the initial lookup.

Note

Reducing the IA range or concatenating translation tables affects only the initial lookup.

The following sections describe full VMSAv8-64 translation flows, down to an entry for a memory page:

- *The address and properties fields shown in the translation flows on page K6-6188.*
- *Full translation flow using the 4KB granule and starting at level 0 on page K6-6189.*
- *Full translation flow using the 4KB granule and starting at level 1 on page K6-6190.*
- *Full translation flow using the 64KB granule and starting at level 1 on page K6-6191.*
- *Full translation flow using the 64KB granule and starting at level 2 on page K6-6192.*

The address and properties fields shown in the translation flows

For the Non-secure EL1&0 stage 1 translation:

- Any descriptor address is the IPA of the required descriptor.
- The final output address is the IPA of the block or page.

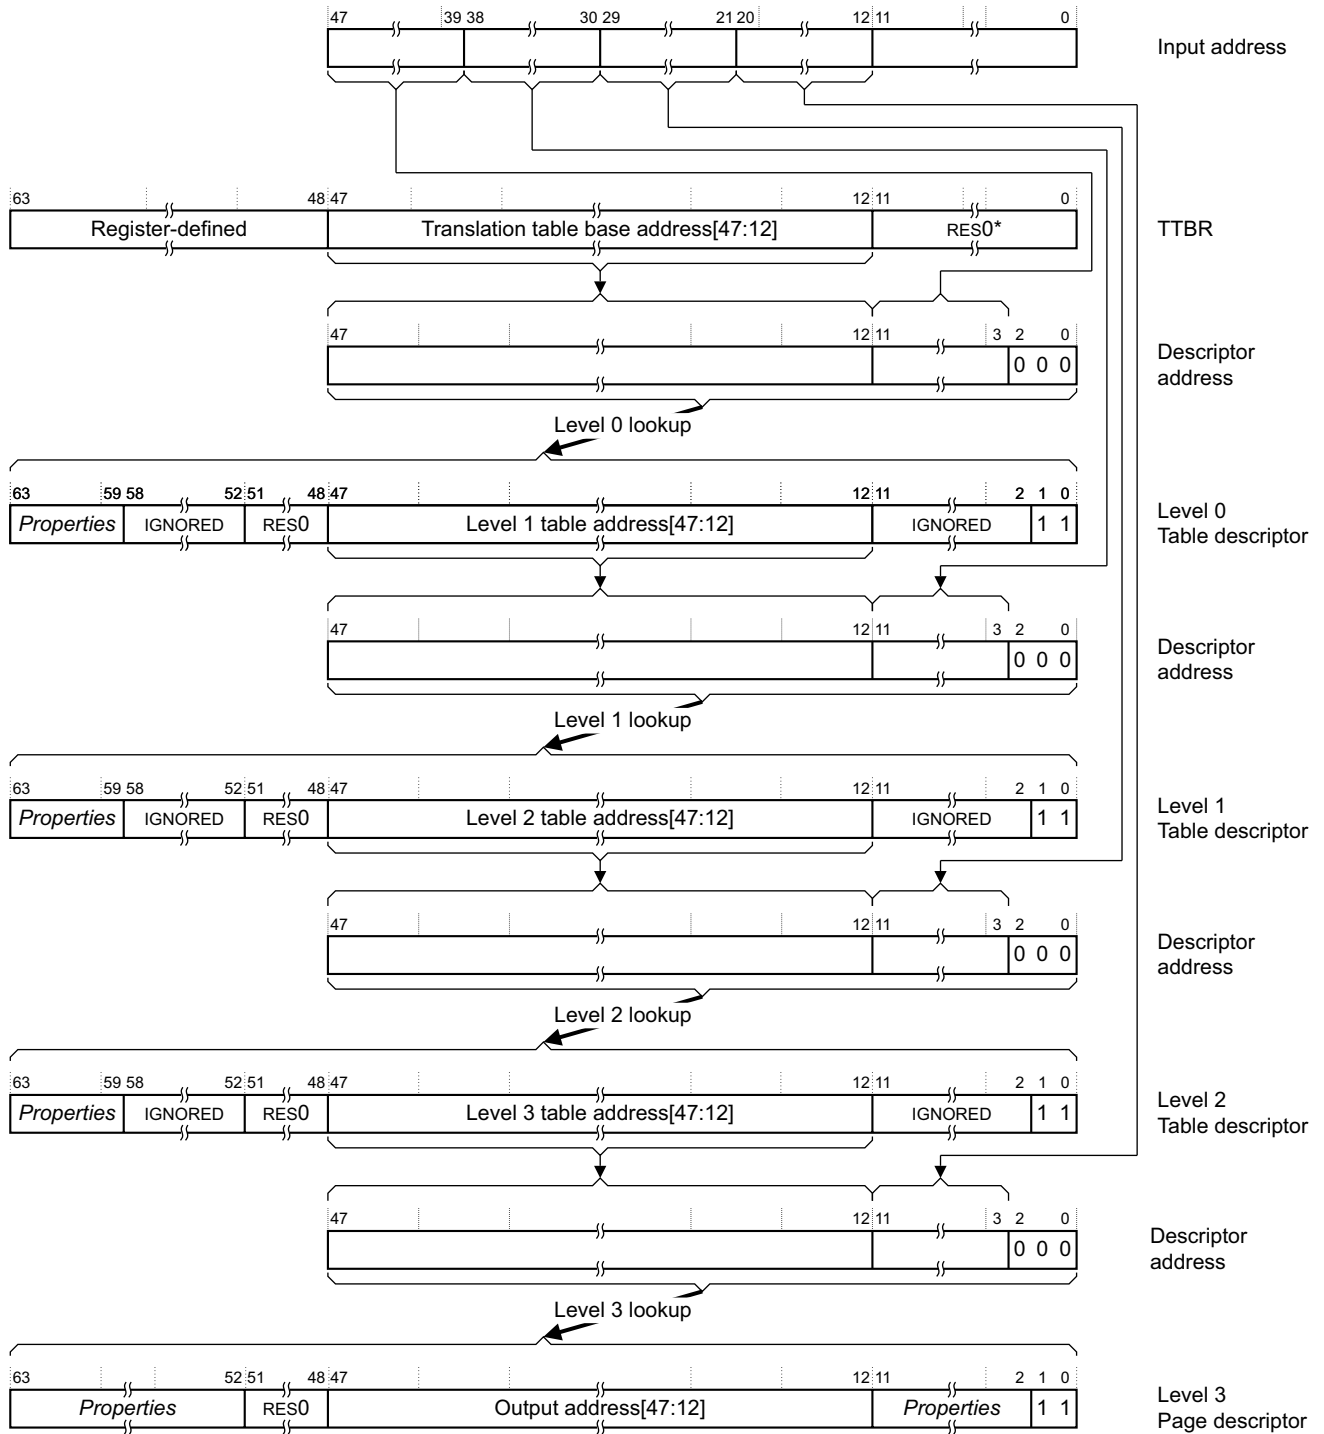

In these cases, an EL1&0 stage 2 translation is performed to translate the IPA to the required PA.

For all other translations, the final output address is the PA of the block or page, and any descriptor address is the PA of the descriptor.

Properties indicates register or translation table fields that return information, other than address information, about the translation or the targeted memory region. For more information see [Memory attribute fields in the VMSAv8-64 translation table format descriptors](#) on page D4-2064.

Full translation flow using the 4KB granule and starting at level 0

Figure K6-10 shows the complete translation flow for a stage 1 translation table walk for a 48-bit input address. This lookup must start with a level 0 lookup. For more information about the fields shown in the figure see *The address and properties fields shown in the translation flows* on page K6-6188.

For details of *Properties* fields, see the register or descriptor description.

* Field has additional properties to the default RES0 definition, see the register description for more information.

Figure K6-10 Complete stage 1 translation of a 48-bit address using the 4KB translation granule

If the level 1 lookup or level 2 lookup returns a block descriptor then the translation table walk completes at that level.

Figure K6-10 on page K6-6189 shows a stage 1 translation. The only difference for a stage 2 translation is that bits[63:58] of the Table descriptors are SBZ.

Full translation flow using the 4KB granule and starting at level 1

Figure K6-11 shows the complete translation flow for a stage 1 translation table walk for a 39-bit input address. This lookup must start with a level 1 lookup. For more information about the fields shown in the figure see *The address and properties fields shown in the translation flows on page K6-6188*.

For details of *Properties* fields, see the register or descriptor description.

* Field has additional properties to the default RES0 definition, see the register description for more information.

Figure K6-11 Complete stage 1 translation of a 39-bit address using the 4KB translation granule

If the level 1 lookup or the level 2 lookup returns a block descriptor then the translation table walk completes at that level.

Figure K6-11 on page K6-6190 shows a stage 1 translation. The only difference for a stage 2 translation is that bits[63:58] of the Table descriptors are SBZ.

Comparing this translation with the translation for a 48-bit address, shown in Figure K6-10 on page K6-6189, shows how the translation for the 42-bit address start the same lookup process one stage later.

Full translation flow using the 64KB granule and starting at level 1

Figure K6-10 on page K6-6189 shows the complete translation flow for a stage 1 translation table walk for a 48-bit input address. This lookup must start with a level 0 lookup. For more information about the fields shown in the figure see *The address and properties fields shown in the translation flows on page K6-6188*.

For details of *Properties* fields, see the register or descriptor description.
* Field has additional properties to the default RES0 definition, see the register description for more information.

Figure K6-12 Complete stage 1 translation of a 48-bit address using the 64KB translation granule

If the level 2 lookup returns a block descriptor then the translation table walk completes at that level.

Figure K6-12 shows a stage 1 translation. The only difference for a stage 2 translation is that bits[63:58] of the Table descriptors are SBZ.

The level 1 lookup resolves only 6 bits of the input address. As described in *Performing the initial lookup using the 64KB translation granule* on page K6-6185, this means:

- The translation table size for this level is only 512 bytes.
- The required translation table alignment for this level is 512 bytes.
- The Base address field in the `TTBR_ELx` is extended, at the low-order end, to be bits[47:9].

Full translation flow using the 64KB granule and starting at level 2

Figure K6-11 on page K6-6190 shows the complete translation flow for a stage 1 translation table walk for a 42-bit input address. This lookup must start with a level 2 lookup. For more information about the fields shown in the figure see *The address and properties fields shown in the translation flows* on page K6-6188.

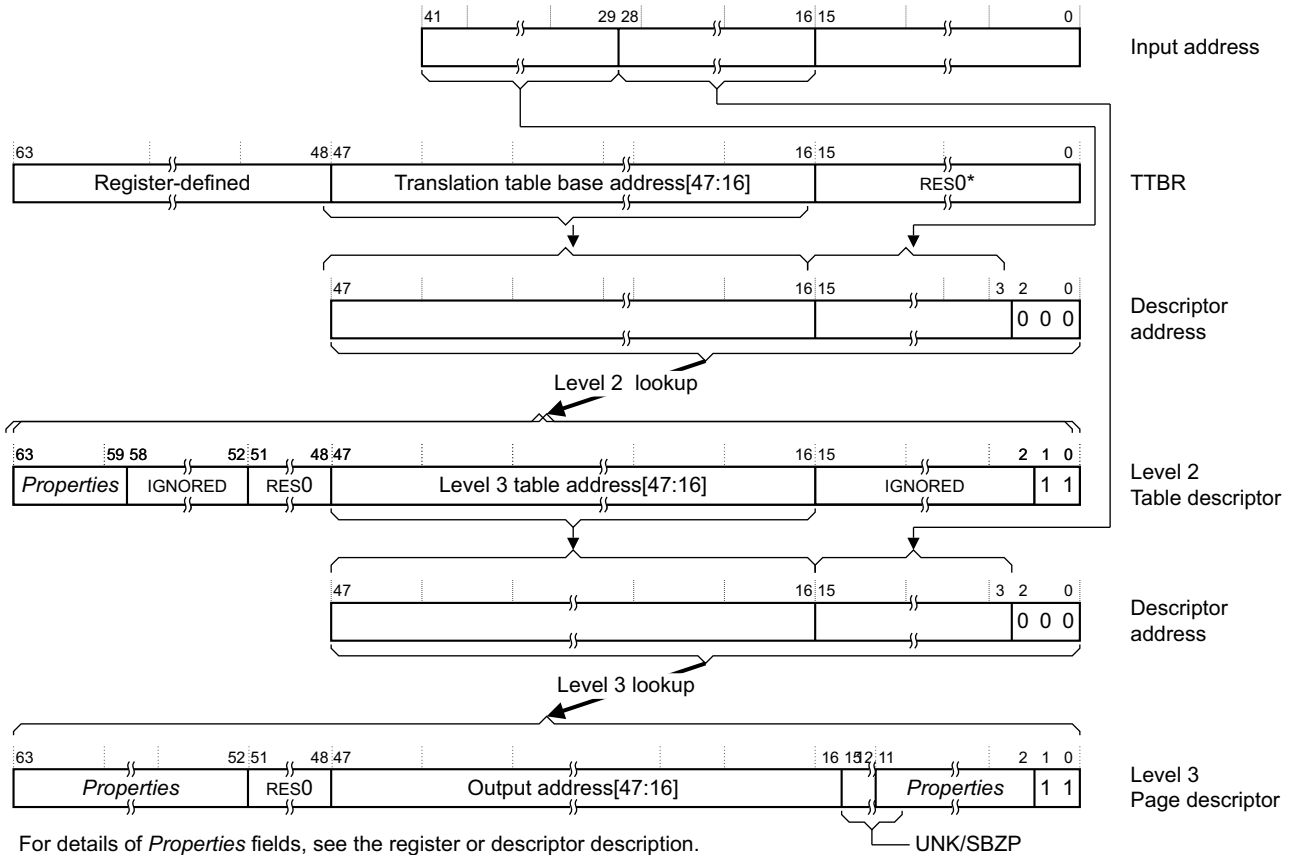

Figure K6-13 Complete stage 1 translation of a 42-bit address using the 64KB translation granule

If the level 2 lookup returns a block descriptor then the translation table walk completes at that level.

Figure K6-13 shows a stage 1 translation. The only difference for a stage 2 translation is that bits[63:58] of the Table descriptors are SBZ.

Comparing this translation with the translation for a 48-bit address, shown in Figure K6-12 on page K6-6191, shows:

- The translation for the 42-bit address starts the same lookup process one stage later.
- Because the initial lookup resolves 13 bits of address:
 - The translation table size for this level is 64KB.
 - The required translation table alignment for this level is 64KB.
 - The Base address field in the `TTBR_ELx` is bits[47:16].

K6.2 AArch32 Address translation examples

The following sections give address translation examples for the VMSSAv8-32 address translation formats:

- [Address translation examples using the VMSSAv8-32 Short descriptor translation table format.](#)
- [Address translation examples using the VMSSAv8-32 Long descriptor translation table format on page K6-6198.](#)

K6.2.1 Address translation examples using the VMSSAv8-32 Short descriptor translation table format

[VMSSAv8-32 Short-descriptor translation table format descriptors on page G4-4577](#) describes the memory section and page option for a single VMSSAv8-32 address translation. The following sections show the full translation flow for each of these options:

- [Translation flow for a Supersection on page K6-6194.](#)
- [Translation flow for a Section on page K6-6195.](#)
- [Translation flow for a Large page on page K6-6196.](#)
- [Translation flow for a Small page on page K6-6197.](#)

[The address and Properties fields shown in the translation flows on page K6-6198](#) summarizes the information returned by the lookup.

Translation flow for a Supersection

Figure K6-14 shows the complete translation flow for a Supersection. For more information about the fields shown in this figure see *The address and Properties fields shown in the translation flows* on page K6-6198.

‡ This field is absent if N is 0
 BA = Base address
 For a translation based on TTBR0, N is the value of TTBCR.N
 For a translation based on TTBR1, N is 0
 For details of *Properties* fields, see the register or descriptor description

Figure K6-14 VMSAv8-32 Short-descriptor Supersection address translation

Note

Figure K6-14 shows how, when the input address, the VA, addresses a Supersection, the top four bits of the *Supersection index* bits of the address overlap the bottom four bits of the *Table index* bits. For more information, see *Additional requirements for Short-descriptor format translation tables* on page G4-4580.

Translation flow for a Section

Figure K6-15 shows the complete translation flow for a Section. For more information about the fields shown in this figure see *The address and Properties fields shown in the translation flows on page K6-6198*.

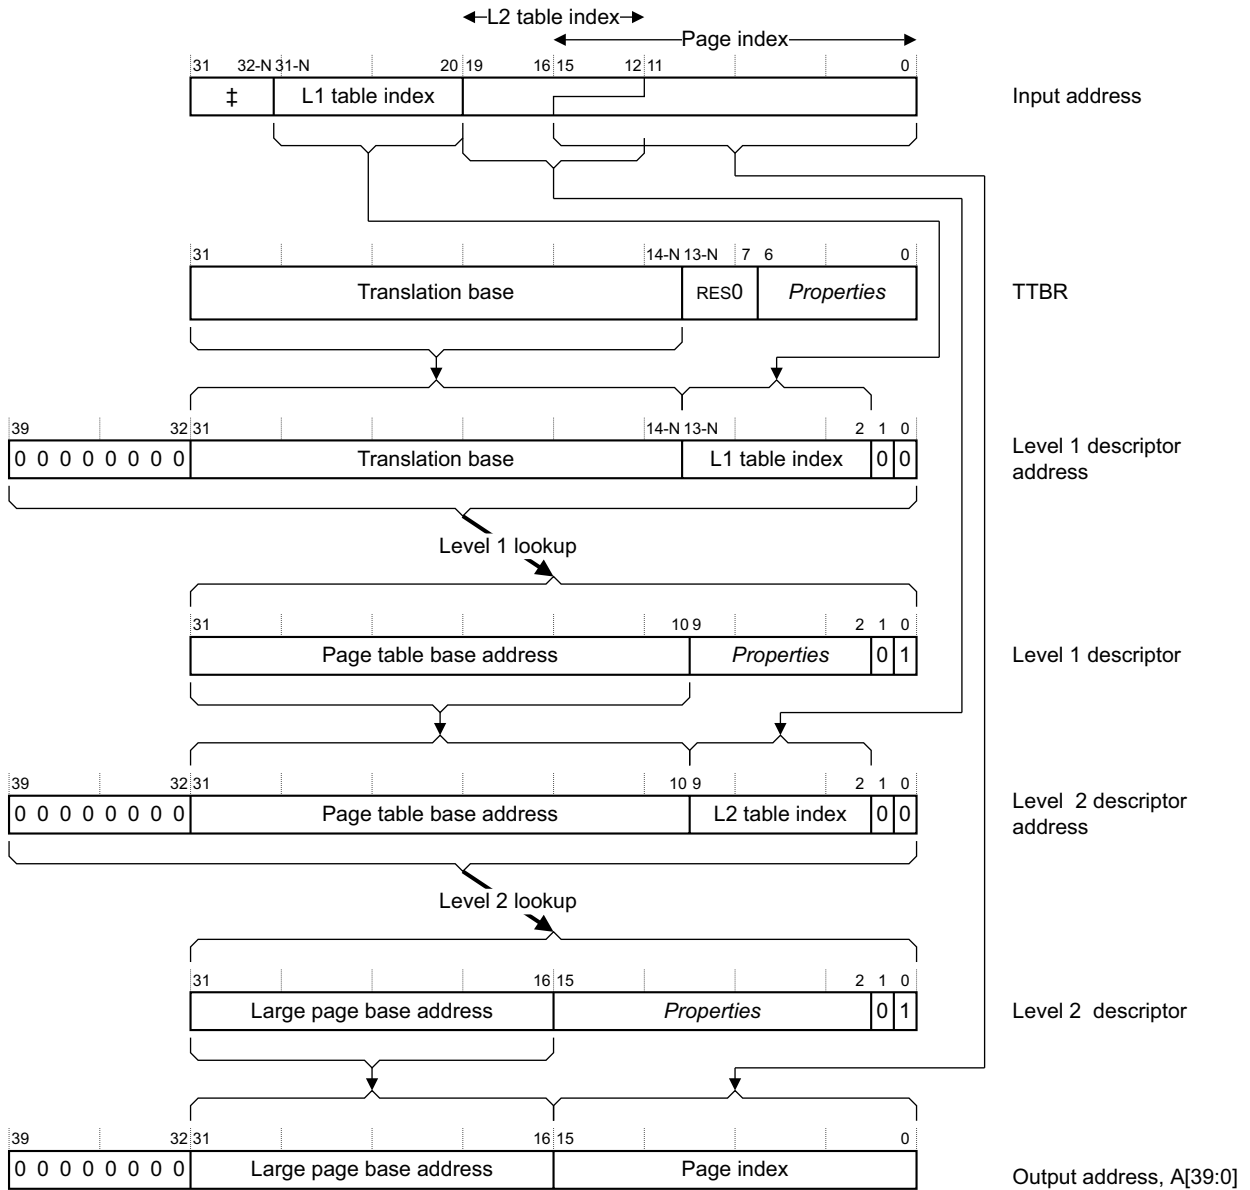

‡ This field is absent if N is 0
 For a translation based on TTBR0, N is the value of TTBCR.N
 For a translation based on TTBR1, N is 0
 For details of *Properties* fields, see the register or descriptor description.

Figure K6-15 VMSAv8-32 Short-descriptor Section address translation

Translation flow for a Large page

Figure K6-16 shows the complete translation flow for a Large page. For more information about the fields shown in this figure see *The address and Properties fields shown in the translation flows on page K6-6198*.

‡ This field is absent if N is 0
 L1 = Level 1, L2 = Level 2
 For a translation based on TTBR0, N is the value of TTBCR.N
 For a translation based on TTBR1, N is 0
 For details of *Properties* fields, see the register or descriptor description

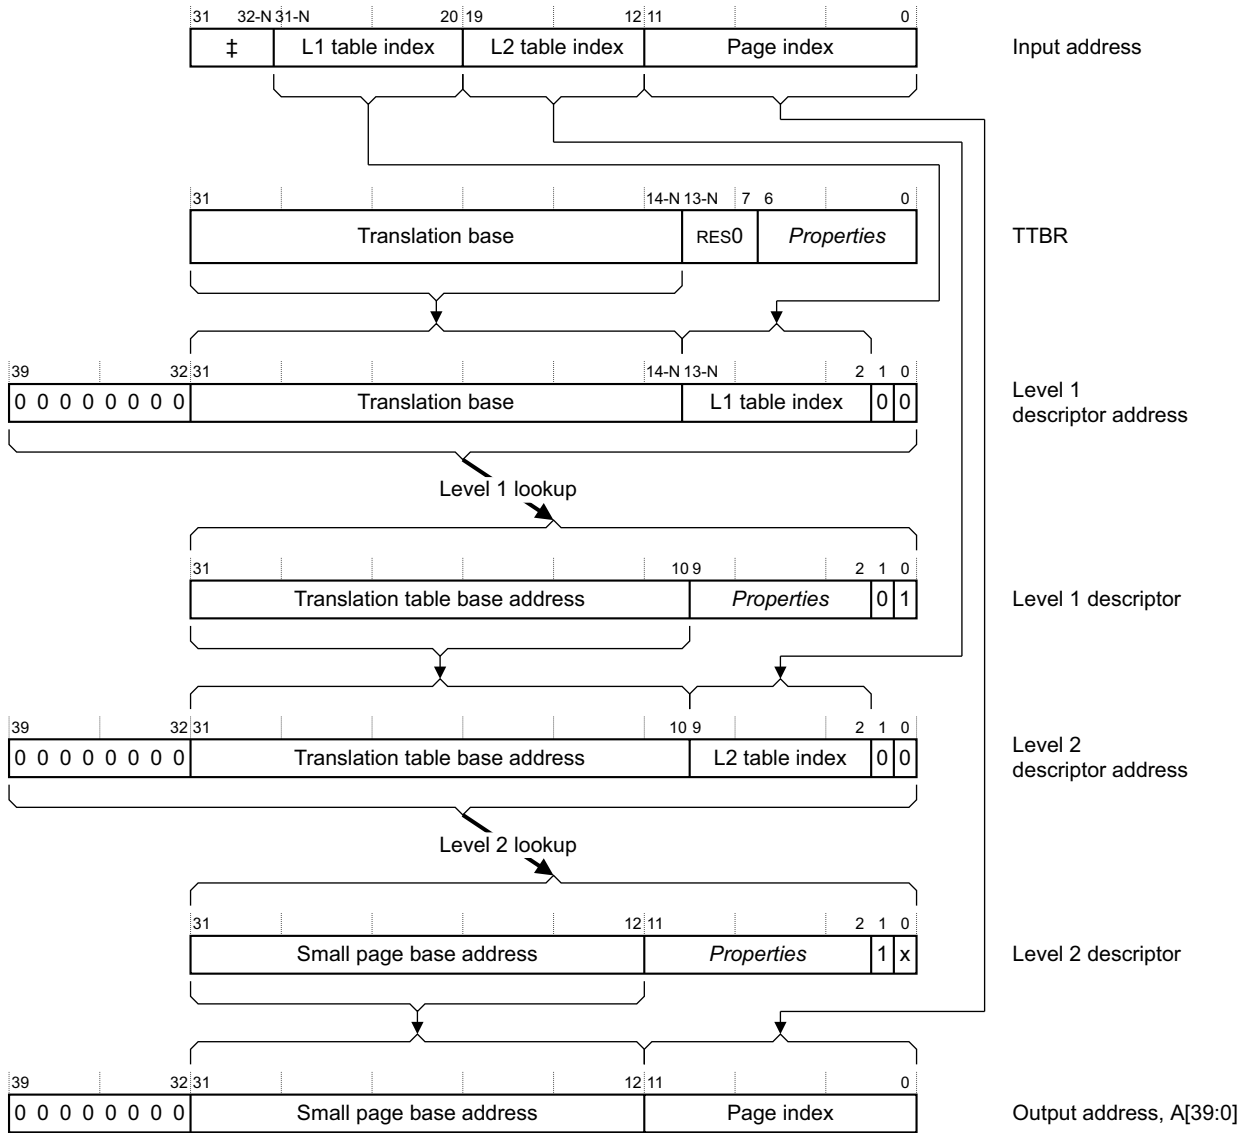

Figure K6-16 VMSAv8-32 Short-descriptor Large page address translation

Note

Figure K6-16 shows how, when the input address, the VA, addresses a Large page, the top four bits of the *page index* bits of the address overlap the bottom four bits of the *level 1 table index* bits of the address. For more information, see *Additional requirements for Short-descriptor format translation tables on page G4-4580*.

Translation flow for a Small page

Figure K6-17 shows the complete translation flow for a Small page. For more information about the fields shown in this figure see *The address and Properties fields shown in the translation flows on page K6-6198*.

‡ This field is absent if N is 0
L1 = Level 1, L2 = Level 2
For a translation based on TTBR0, N is the value of TTBCR.N
For a translation based on TTBR1, N is 0
For details of *Properties* fields, see the register or descriptor description.

Figure K6-17 VMSAv8-32 Short-descriptor Small page address translation

The address and Properties fields shown in the translation flows

For the Non-secure PL1&0 stage 1 translation tables:

- Any descriptor address is the IPA of the required descriptor.
- The final output address is the IPA of the Section, Supersection, Large page, or Small page.

In these cases, a PL1&0 stage 2 translation is performed to translate the IPA to the required PA.

Otherwise, the address is the PA of the descriptor, Section, Supersection, Large page, or Small page.

Properties indicates register or translation table fields that return information, other than address information, about the translation or the targeted memory region. For more information see [Information returned by a translation table lookup on page G4-4572](#), and the description of the register or translation table descriptor.

For translations using the Short-descriptor translation table format, [VMSAv8-32 Short-descriptor translation table format descriptors on page G4-4577](#) describes the descriptors formats.

K6.2.2 Address translation examples using the VMSAv8-32 Long descriptor translation table format

As described in [Translation table walks, when using the VMSAv8-32 Long-descriptor translation table format on page G4-4600](#), in a translation table walk, only the first lookup uses the translation table base address from the appropriate [TTBR](#). Subsequent lookups use a combination of address information from:

- The table descriptor read in the previous lookup.
- The input address.

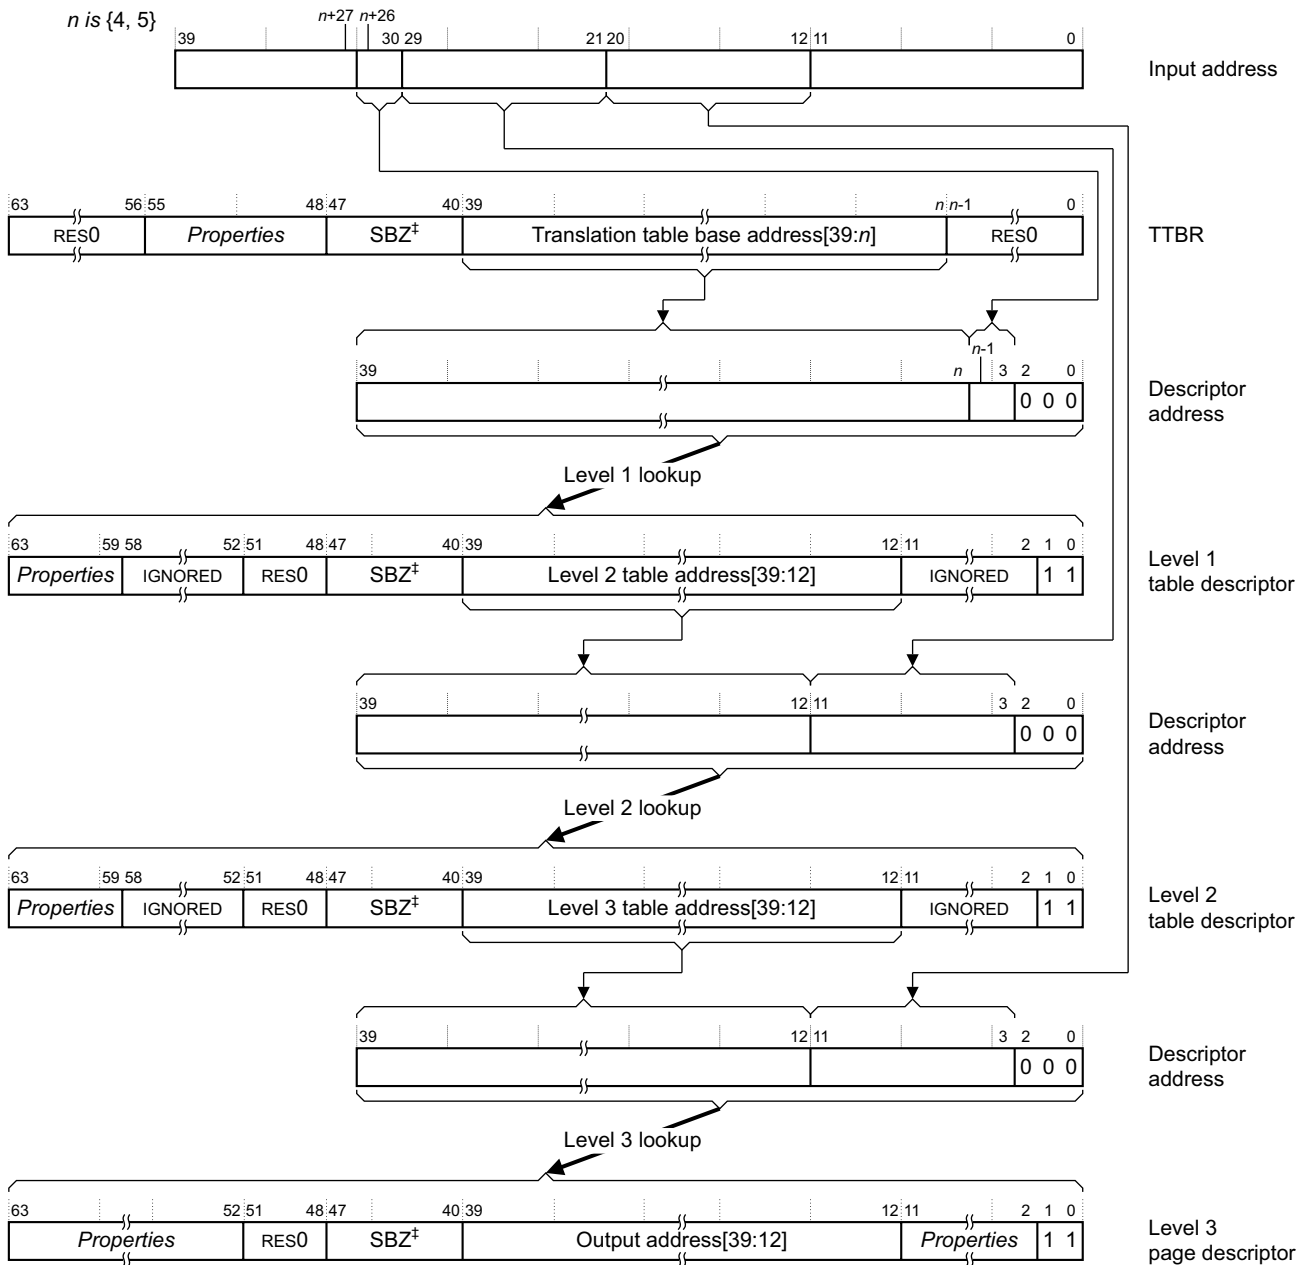

The following sections give examples of full VMSAv8-32 Long-descriptor format address translation flows, down to an entry for a 4KB page:

- [Full translation flow, starting at level 1 lookup on page K6-6199](#).
- [Full translation flow, starting at level 2 lookup on page K6-6200](#).

[The address and Properties fields shown in the translation flows](#) summarizes the information returned by the lookup.

Full translation flow, starting at level 1 lookup

Figure K6-18 shows the complete translation flow for a VMSAv8-32 Long-descriptor stage 1 translation table walk that starts with a level 1 lookup. For more information about the fields shown in the figure see *The address and Properties fields shown in the translation flows* on page K6-6198.

For details of *Properties* fields, see the register or descriptor description.

‡ See the lookup description for more information about bits[40:47] of the TTBR and descriptors

Figure K6-18 Complete VMSAv8-32 Long-descriptor format stage 1 translation, starting at level 1

If the level 1 lookup or the level 2 lookup returns a block descriptor then the translation table walk completes at that level.

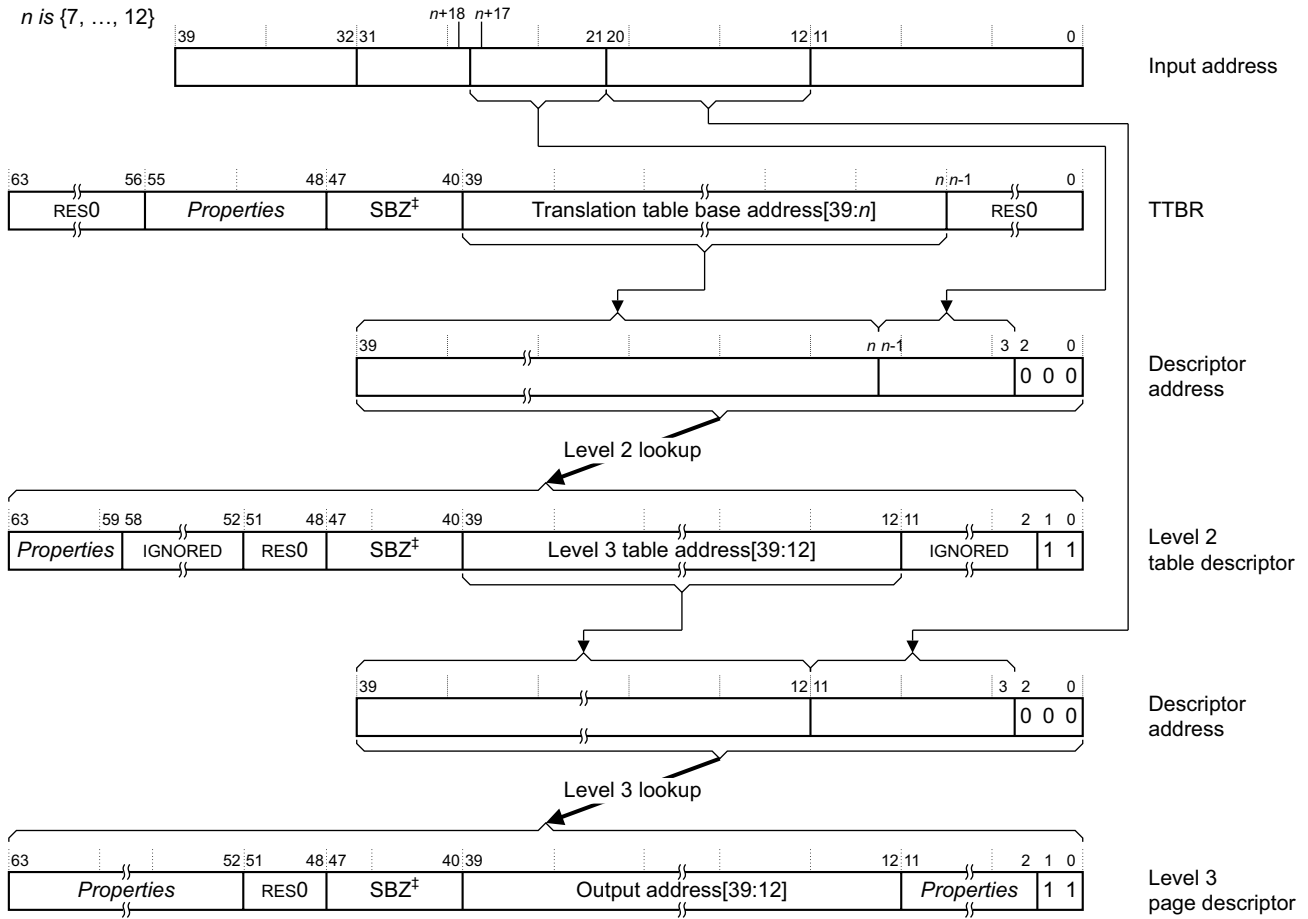

If bits[47:40] of the TTBR or the descriptor are not zero then the lookup will generate an Address size fault, see *Address size fault* on page G4-4658.

A stage 2 translation that starts at a level 1 lookup differs from the translation shown in [Figure K6-18 on page K6-6199](#) only as follows:

- The possible values of n are 4-13, to support an input address of between 31 and 40 bits.
- A descriptor and output addresses are always PAs.

Full translation flow, starting at level 2 lookup

[Figure K6-19](#) shows the complete translation flow for a stage 1 VMSAv8-32 Long-descriptor translation table walk that starts at a level 2 lookup. For more information about the fields shown in the figure see [The address and Properties fields shown in the translation flows on page K6-6198](#).

For details of *Properties* fields, see the register or descriptor description.
[‡] See the lookup description for more information about bits[40:47] of the TTBR and descriptors

Figure K6-19 Complete VMSAv8-32 Long-descriptor format stage 1 translation, starting at level 2

If the level 2 lookup returns a block descriptor then the translation table walk completes at that level.

If bits[47:40] of the **TTBR** or the descriptor are not zero then the lookup will generate an Address size fault, see [Address size fault on page G4-4658](#).

A stage 2 translation that starts at a level 2 lookup differs from the translation shown in [Figure K6-19](#) only as follows:

- The possible values of n are 7-16, to support an input address of up to 34 bits.
- The descriptor and output addresses are always PAs.

The address and Properties fields shown in the translation flows

For the Non-secure PL1&0 stage 1 translation:

- Any descriptor address is the IPA of the required descriptor.
- The final output address is the IPA of the block or page.

In these cases, a PL1&0 stage 2 translation is performed to translate the IPA to the required PA.

For all other translations, the final output address is the PA of the block or page, and any descriptor address is the PA of the descriptor.

Properties indicates register or translation table fields that return information, other than address information, about the translation or the targeted memory region. For more information see [Information returned by a translation table lookup on page G4-4572](#), and the description of the register or translation table descriptor.

For translations using the Long-descriptor translation table format, [VMSAv8-32 Long-descriptor translation table format descriptors on page G4-4586](#) describes the descriptors formats.

Appendix K7

Example OS Save and Restore Sequences

This appendix provides possible OS Save and Restore sequences for a v8 Debug implementation. It contains the following sections:

- [Save Debug registers on page K7-6204.](#)
- [Restore Debug registers on page K7-6206.](#)

K7.1 Save Debug registers

This section shows how to save the registers that are used by an external debugger.

; On entry, X0 points to a block to save the debug registers in.
 ; Returns the pointer beyond the block and corrupts X1-X3

SaveDebugRegisters

```
; (1) Set OS lock.
MOV    X2,#1                ; Set the OS lock. In AArch64 state, the OS lock
MSR    OSLAR_EL1,X2        ; is writable via OSLAR.
ISB                                ; Context synchronization event
```

```
; (2) Walk through the registers, saving them
MRS    X1,OSDTRRX_EL1      ; Read DTRRX
MRS    X2,OSDTRTX_EL1      ; Read DTRTX
STP    W1,W2,[X0],#8       ; Save { DTRRX, DTRTX }
MRS    X1,OSECCR_EL1       ; Read ECCR
MRS    X2,MDSCR_EL1        ; Read DSCR
STP    W1,W2,[X0],#8       ; Save { ECCR, DSCR }
[ AARCH32_SUPPORTED
MRS    X1,DBGVCR32_EL2     ; Read DBGVCR
MRS    X2,DBGCLAIMCLR_EL1  ; Read CLAIM - note, have to read via CLAIMCLR
STP    W1,W2,[X0],#8       ; Save { VCR, CLAIM }
]
```

```
; Macros for saving off a "register pair"
;; $WB      is W for watchpoint, B for breakpoint
;; $num     is the pair's number

```

Appendix K8

Recommended Upload and Download Processes for External Debug

This appendix contains the following section:

- [Using memory access mode in AArch64 state on page K8-6210.](#)

———— **Note** —————

This description is not part of the ARM architecture specification. It is included here as supplementary information, for the convenience of developers and users who might find this information useful.

—————

K8.1 Using memory access mode in AArch64 state

Figure K8-1 and Figure K8-2 on page K8-6211 show the processes for using memory access mode to implement a download (external host to target) and an upload (target to external host).

To transfer n words of data:

- The download sequence needs $n+6$ accesses by the external debug interface.
- The upload sequence needs $n+8$ accesses by the external debug interface.

In both cases, in the innermost loop the debugger can make an external access to a DTR without polling `EDSCR` after each write as underrun and overrun detection prevent failure. Normally external accesses from the debugger are outpaced by the memory accesses of the PE, making underruns and overruns unlikely. If this is not the case, the `EDSCR.ERR` flag is set to 1. This is checked once at the end of the sequence, although a debugger can check it more often, for example once for each page. If the `EDSCR.ERR` flag is set to 1 because of overrun or underrun, the debugger can restart. The address to restart from is frozen in `X0`. `EDSCR.ERR` might also be set because of a Data abort.

If underruns and overruns are common, the debugger can pace itself accordingly.

———— **Note** ————

- The base address must be a multiple of 4.
- The order of the writes that set up the address does not matter in Debug state.

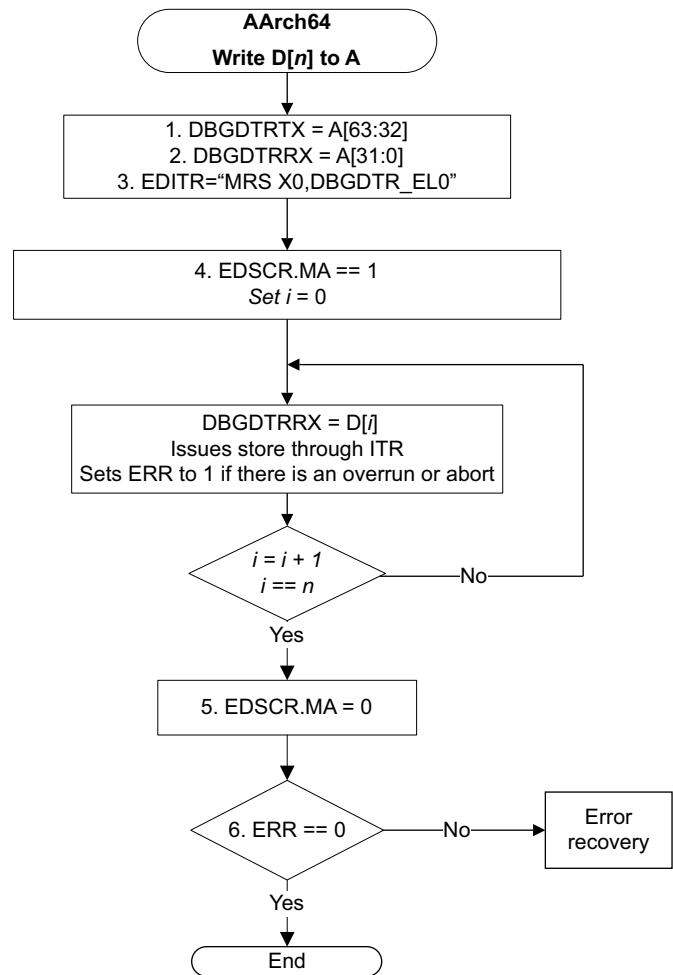

Figure K8-1 Fast code download in AArch64 state (external host to target)

In Figure K8-1 on page K8-6210, the sequence for the fast code download is as follows:

1. Setup. From the external debug interface:
 - a. Write address [31:0] to `DBGDTRRX_EL0`.
 - b. Write address [63:32] to `DBGDTRTX_EL0`.
 - c. Write `MRS X0, DBGDTR_EL0` to `EDITR`. The PE executes this instruction.
 - d. Set `EDSCR.MA` to 1.
2. Loop n times. From the external debug interface:
 - a. Write to `DBGDTRRX_EL0`. The PE reads the word from `DTRRX` and stores it to memory. It increments `X0` by 4.
3. Epilogue. From the external debug interface:
 - a. Clear `EDSCR.MA` to 0.
 - b. Read `EDSCR` to check for overruns or Data Aborts during download.

Figure K8-2 Fast data upload in AArch64 state (target to external host)

In Figure K8-2 on page K8-6211, the sequence for the fast code download is as follows:

1. Setup. From the external debug interface:
 - a. Write address [31:0] to `DBGDTRRX_EL0`.
 - b. Write address [63:32] to `DBGDTRTX_EL0`.
 - c. Write MRS `X0`, `DBGDTR_EL0` to `EDITR`.
 - d. Write MSR `DBGDTR_EL0`, `X0` to `EDITR`. This dummy operation ensures `EDSCR.TXfull == 1`.
 - e. Set `EDSCR.MA` to 1.
 - f. Read `DBGDTRTX_EL0` and discard the value. The PE returns the previous DTR value, loads the first word, and writes it to DTR. It increments `X0` by 4.
2. Loop $n-1$ times. From the external debug interface:
 - a. Read `DBGDTRTX_EL0`. The PE returns the previous DTRTX value, loads a new word, and writes it to DTRTX. It increments `X0` by 4.
3. Epilogue. From the external debug interface:
 - a. Clear `EDSCR.MA` to 0.
 - b. Read `DBGDTRTX_EL0` for the n^{th} value.
 - c. Read `EDSCR` to check for underruns, overruns or Data Aborts during upload.

Appendix K9

Barrier Litmus Tests

This appendix gives examples of the use of the barrier instructions provided by the ARMv8 architecture. It contains the following sections:

- [Introduction on page K9-6214.](#)
- [Load-Acquire, Store-Release and barriers on page K9-6217.](#)
- [Load-Acquire Exclusive, Store-Release Exclusive and barriers on page K9-6221.](#)
- [Using a mailbox to send an interrupt on page K9-6226.](#)
- [Cache and TLB maintenance instructions and barriers on page K9-6227.](#)
- [ARMv7 compatible approaches for ordering, using DMB and DSB barriers on page K9-6239.](#)

———— **Note** —————

This information is not part of the ARM architecture specification. It is included here as supplementary information, for the convenience of developers and users who might require this information.

K9.1 Introduction

The exact rules for the insertion of barriers into code sequences is a very complicated subject, and this appendix describes many of the corner cases and behaviors that are possible in an implementation of the ARMv8 architecture.

This appendix is to help programmers, hardware design engineers, and validation engineers understand the need for the different kinds of barriers.

K9.1.1 Overview of memory consistency

Early generations of microprocessors were relatively simple processing engines that executed each instruction in program order. In such processors, the effective behavior was that each instruction was executed in its entirety before a subsequent instruction started to be executed. This behavior is sometimes referred to as the *Sequential Execution Model* (SEM), and in this Manual it is described as *Simple sequential execution* of the program.

In later processor generations, the needs to increase processor performance, both in terms of the frequency of operation and the number of instructions executed each cycle, mean that such a simple form of execution is abandoned. Many techniques, such as pipelining, write buffering, caching, speculation, and out-of-order execution, are introduced to provide improved performance.

For general purpose PEs, such as ARM, these microarchitectural innovations are largely hidden from the programmer by a number of microarchitectural techniques. These techniques ensure that, within an individual PE, the behavior of the PE largely remains the same as the SEM. There are some exceptions to this where explicit synchronization is required. In the ARM architecture, these are limited to cases such as:

- Synchronization of changes to the instruction stream.
- Synchronization of changes to System registers.

In both these cases, the ISB instruction provides the necessary synchronization.

While the effect of ordering is largely hidden from the programmer within a single PE, the microarchitectural innovations have a profound impact on the ordering of memory accesses. Write buffering, speculation, and cache coherency protocols, in particular, can all mean that the order in which memory accesses occur, as seen by an external observer, differs significantly from the order of accesses that would appear in the SEM. This is usually invisible in a uniprocessor environment, but the effect becomes much more significant when multiple PEs are trying to communicate with memory. In reality, these effects are often only significant at particular synchronization boundaries between the different threads of execution.

The problems that arise from memory ordering considerations are sometimes described as the problem of *memory consistency*. Processor architectures have adopted one or more *memory consistency models*, or *memory models*, that describe the permitted limits of the memory re-ordering that can be performed by an implementation of the architecture. The comparison and categorization of these has generated significant research and comment in academic circles, and ARM recommends the *Memory Consistency Models for Shared Memory-Multiprocessors* paper as an excellent detailed treatment of this subject.

This appendix does not reproduce such a work, but instead concentrates on some cases that demonstrate the features of the weakly-ordered memory model of the ARM architecture from ARMv6. In particular, the examples show how the use of the DMB and DSB memory barrier instructions can provide the necessary safeguards to limit memory ordering effects at the required synchronization points.

K9.1.2 Barrier operation definitions

The following reference, or provide, definitions of terms used in this appendix:

DMB See *Data Memory Barrier (DMB)* on page B2-92.

DSB See *Data Synchronization Barrier (DSB)* on page B2-93.

ISB See *Instruction Synchronization Barrier (ISB)* on page B2-92.

Observer, Completion

See *Definition of the ARMv8 memory model* on page B2-86.

See *Completion and endpoint ordering* on page B2-91.

Program order

The order of instructions as they appear in an assembly language program. This appendix does not attempt to describe or define the legal transformations from a program written in a higher level programming language, such as C or C++, into the machine language that can then be disassembled to give an equivalent assembly language program. Such transformations are a function of the semantics of the higher level language and the capabilities and options on the compiler.

K9.1.3 Conventions

Many of the examples are written in a stylized extension to ARM assembler, to avoid confusing the examples with unnecessary code sequences.

AArch32

The construct `WAIT([Rx]==1)` describes the following sequence:

```
loop
  LDR R12, [Rx]
  CMP R12, #1
  BNE loop
```

Also, the construct `WAIT_ACQ([Rx]==1)` describes the following sequence:

```
loop
  LDA R12, [Rx]      ; load acquire ensures it is ordered before subsequent loads/stores
  CMP R12, #1
  BNE loop
```

R12 is chosen as an arbitrary temporary register that is not in use. It is named to permit the generation of a false dependency to ensure ordering.

AArch64

The construct `WAIT([Xx]==1)` describes the following sequence:

```
loop
  LDR W12, [Xx]
  CMP W12, #1
  B.NE loop
```

Also, the construct `WAIT_ACQ([Xx]==1)` and describes the following sequence:

```
loop
  LDAR W12, [Xx]    ; load acquire ensures it is ordered before subsequent loads/stores
  CMP W12, #1
  B.NE loop
```

For each example, a code sequence is preceded by an identifier of the observer running it:

- P0, P1...Px refer to caching coherent PEs that implement the ARMv8 architecture, and are in the same shareability domain.
- E0, E1...Ex refer to non-caching observers, that do not participate in the coherency protocol, but execute ARM instructions and have a weakly-ordered memory model. This does not preclude these observers being different objects, such as DMA engines or other system masters.

These observers are unsynchronized other than as required by the documented code sequence.

———— Note —————

Throughout this appendix, *ARM instruction* and *instruction* refer to instructions from the A64, A32, or T32 instruction set, provided by ARMv8 implementations.

Results are expressed in terms of <agent>:<register>, such as P0:R5. The results can be described as:

Permissible This does not imply that the results expressed are required or are the only possible results. In most cases they are results that would not be possible under a sequentially consistent running of the code sequences on the agents involved. In general terms, this means that these results might be unexpected to anyone unfamiliar with memory consistency issues.

Not permissible Results that the architecture expressly forbids.

Required Results that the architecture expressly requires.

The examples omit the required shareability domain arguments of DMB and DSB instructions. The arguments are assumed to be selected appropriately for the shareability domains of the observers.

In AArch32 state, where the barrier function in the litmus test can be achieved by a DMB ST, that is a barrier to stores only, this is shown by the use of DMB [ST]. This indicates that the ST qualifier can be omitted without affecting the result of the test. In some implementations DMB ST is faster than DMB.

For AArch64 code, the shareability domain of the DMB or DSB must be included. This is shown in this manual using the notation DMB <domain> and DSB <domain> respectively.

Except where otherwise stated, other conventions are:

- All memory initializes to 0.
- R0 and W0 contain the value 1.
- R1 - R4 and W1 - W4 contain arbitrary independent addresses that initialize to the same value on all PEs. The addresses held in these registers are shareable and:
 - The addresses held in R1 and R2 are in Write-Back Cacheable Normal memory.
 - The address held in R3 is in Write-Through Cacheable Normal memory.
 - The address held in R4 is in Non-cacheable Normal memory.
- R5 - R8 and W5 - W8 contain:
 - When used with an STR instruction, 0x55, 0x66, 0x77, and 0x88 respectively.
 - When used with an LDR instruction, the value 0.
- R11 and W11 contain a new instruction or new translation table entry, as appropriate, and R10 contains the virtual address and the ASID, for use in this change of translation table entry.
- Memory locations are Normal memory locations unless otherwise stated.

The examples use mnemonics for the cache maintenance and TLB maintenance instructions. The following tables describe the mnemonics:

- [Cache maintenance instructions, functional group on page G4-4734.](#)
- [TLB maintenance instructions, functional group on page G4-4735.](#)

K9.2 Load-Acquire, Store-Release and barriers

The Load-Acquire and Store-Release instructions are described in [Load-Acquire, Store-Release](#) on page B2-94.

The following sections show that most of the examples in sections [Simple ordering and barrier cases](#) on page K9-6239 and [Load-Exclusive, Store-Exclusive and barriers](#) on page K9-6243 can be achieved using the Load-Acquire and Store-Release instructions without the need for additional barriers.

K9.2.1 Message passing

The following sections describe:

- [Resolving weakly-ordered message passing by using Acquire and Release.](#)
- [Resolving message passing by the use of Store-Release and address dependency](#) on page K9-6218.

Resolving weakly-ordered message passing by using Acquire and Release

The message passing problem described in [Weakly-ordered message passing problem](#) on page K9-6239 can be solved by the use of Load-Acquire and Store-Release instructions when accessing the communications flag:

AArch32

P1

```
STR R5, [R1]           ; sets new data
STL R0, [R2]           ; sends flag indicating data ready, which is ordered after the STR
```

P2

```
WAIT_ACQ([R2]==1)     ; waits on flag
LDR R5, [R1]
```

AArch64

P1

```
STR W5, [X1]           ; sets new data
STLR W0, [X2]          ; sends flag indicating data ready, which is ordered after the STR
```

P2

```
WAIT_ACQ([X2]==1)     ; waits on flag
LDR W5, [X1]
```

This ensures the observed order of both the reads and the writes allows transfer of data such that the result P2:R5==0x55 is guaranteed.

This approach also works with multiple observers, in a way that further observers use the same sequence as P2 uses:

AArch32

P3

```
WAIT_ACQ([R2]==1)     ; waits on flag
LDR R5, [R1]
```

AArch64

P3

```
WAIT_ACQ([X2]==1)     ; waits on flag
LDR W5, [X1]
```

Resolving message passing by the use of Store-Release and address dependency

The lack of ordering of stores discussed in *Message passing with multiple observers* on page K9-6241 can be resolved by the use of Store-Release for the store of the valid flag by P1, even when the observers are using an address dependency:

AArch32

P1

```
STR R5, [R1]          ; sets new data
STL R0, [R2]          ; sends flag indicating data ready using a Store-Release
```

P2

```
WAIT([R2]==1)
AND R12, R12, #0      ; R12 is the destination of LDR in the WAIT macro
LDR R5, [R1, R12]    ; the load has an address dependency on R12
                     ; and so is ordered after the flag has been seen
```

AArch64

P1

```
STR W5, [X1]          ; sets new data
STLR W0, [X2]         ; sends flag indicating data ready using a Store-Release
```

P2

```
WAIT([X2]==1)
AND W12, W12, WZR     ; W12 is the destination of LDR in the WAIT macro
LDR W5, [X1, X12]    ; the load has an address dependency on W12
                     ; and so is ordered after the flag has been seen
```

This ensures the observed order of the writes allows transfer of data such that P2:R5 and P3:R5 contain the same value of 0x55.

This approach also works with multiple observers, in a way that further observers use the same sequence as P2 uses:

AArch32

P3

```
WAIT([R2]==1)
AND R12, R12, #0      ; R12 is the destination of LDR in the WAIT macro
LDR R5, [R1, R12]    ; the load has an address dependency on R12
                     ; and so is ordered after the flag has been seen
```

AArch64

P3

```
WAIT([X2]==1)
AND W12, W12, WZR     ; R12 is the destination of LDR in the WAIT macro
LDR W5, [X1, X12]    ; the load has an address dependency on W12
                     ; and so is ordered after the flag has been seen
```

K9.2.2 Address dependency with object construction

When accessing an object-oriented data structure, the address dependency rule means that barriers are not required, even when initializing the object. A Store-Release can be used to ensure the order of the update of the base address:

AArch32

P1

```
STR R5, [R1, #offset] ; sets new data in a field
STL R1, [R2]           ; updates base address
```

P2

```
LDR R1, [R2]           ; reads base address
CMP R1, #0             ; checks if it is valid
BEQ null_trap
LDR R5, [R1, #offset] ; uses base address to read field
```

AArch64

P1

```
STR W5, [X1, #offset] ; sets new data in a field
STLR X1, [X2]          ; updates base address
```

P2

```
LDR X1, [X2]           ; reads base address
CMP X1, #0             ; check if it is valid
B.EQ null_trap
LDR W5, [X1, #offset] ; uses base address to read field
```

It is required that P2:R5==0x55 if the null_trap is not taken. This avoids P2 observing a partially constructed object from P1. Significantly, P2 does not need a barrier to ensure this behavior.

The read of the base address in P2 could be a Load-Acquire, but it is not necessary in this case.

K9.2.3 WFE and WFI and barriers

The Wait For Event and Wait For Interrupt instructions permit the PE to suspend execution and enter a low-power state. An explicit DSB barrier instruction is required if it is necessary to ensure memory accesses made before the WFI or WFE are visible to other observers, unless some other mechanism has ensured this visibility. Examples of other mechanism that would guarantee the required visibility are the DMB described in [Posting a store before polling for acknowledgement on page K9-6242](#), or a dependency on a load.

The following example requires the DSB to ensure that the store is visible:

AArch32

```
P1
    STR R0, [R2]
    DSB
Loop
    WFI
    B Loop
```

AArch64

```
P1
    STR W0, [X2]
    DSB <domain>
Loop
    WFI
    B Loop
```

This requirement is unchanged in ARMv8 by the presence of Load-Acquire or Store-Release.

K9.3 Load-Acquire Exclusive, Store-Release Exclusive and barriers

The ARMv8 architecture adds the acquire and release semantics to Load-Exclusive and Store-Exclusive instructions, which allows them to gain ordering acquire and/or release semantics.

The Load-Exclusive instruction can be specified to have acquire semantics, and the Store-Exclusive instruction can be specified to have release semantics. These can be arbitrarily combined to allow the atomic update created by a successful Load-Exclusive and Store-Exclusive pair to have any of:

- No Ordering semantics (using LDREX and STREX).
- Acquire only semantics (using LDAEX and STREX).
- Release only semantics (using LDREX and STLEX).
- Sequentially consistent semantics (using LDAEX and STLEX).

In addition, the ARMv8 specification requires that the clearing of a global monitor will generate an event for the PE associated with the global monitor, which can simplify the use of WFE, by removing the need for a DSB barrier and SEV instruction.

K9.3.1 Acquiring a lock

A common use of Load-Exclusive and Store-Exclusive instructions is to claim a lock to permit entry into a critical region. This is typically performed by testing a lock variable that indicates 0 for a free lock and some other value, commonly 1 or an identifier of the process holding the lock, for a taken lock.

For a critical region, the requirement on taking a lock is usually for acquire semantics, while the clearing of a lock requires release semantics:

AArch32

```
Px
    PLDW[R1]          ; preload into cache in unique state
Loop
    LDAEX R5, [R1]    ; read lock with acquire
    CMP R5, #0        ; check if 0
    STREXEQ R5, R0, [R1] ; attempt to store new value
    CMPEQ R5, #0      ; test if store succeeded
    BNE Loop          ; retry if not

    ; loads and stores in the critical region can now be performed
```

AArch64

```
Px
    PRFM PSTL1KEEP, [X1] ; preload into cache in unique state
Loop
    LDAXR W5, [X1]       ; read lock with acquire
    CBNZ W5, Loop        ; check if 0
    STXR W5, W0, [X1]    ; attempt to store new value
    CBNZ W5, Loop        ; test if store succeeded and retry if not

    ; loads and stores in the critical region can now be performed
```

The acquire associated with the load is sufficient to ensure the required ordering in a lock situation. The Store-Exclusive will fail (and so be retried) if there is a store to the location being monitored between the Load-Exclusive and the Store-Exclusive.

K9.3.2 Releasing a lock

The converse operation of releasing a lock does not require the use of Load-Exclusive and Store-Exclusive instructions, because only a single observer is able to write to the lock. However, often it is necessary for any observer to observe any memory updates, or any values that are loaded into memory, before they observe the release of the lock. Therefore, the lock release needs release semantics:

AArch32

```
Px
; loads and stores in the critical region
MOV R0, #0
STL R0, [R1] ; clear the lock with release semantics
```

AArch64

```
Px
; loads and stores in the critical region
STLR WZR, [X1] ; clear the lock with release semantics
```

K9.3.3 Ticket locks

When a lock is free, in order to avoid a rush to get the lock by many PEs, the use of ticket locks is common in more advanced systems. When the use is requested, the ticket locks determine the order of the users of the critical sections, in order to avoid starvation that can occur with a simple contention based spin lock.

A ticket lock allocates each thread a ticket number when it first requests the lock, and then compares that number with the current number for the lock. If they are the same, then the critical section can be entered. Otherwise the thread waits until the current number is equal to the ticket number for that thread.

The reading of the current number of the lock needs acquire semantics for the lock to be acquired.

———— Note ————

The code in this section is little-endian code, as it views the combined current and next values as a single combined quantity. The addresses of the current and next ticket values need to be adjusted for a big-endian system.

This is shown in the implementation below:

AArch32

```
Px
; R1 holds two 16 bit quantities
; the lower halfword holds the current ticket number
; the higher halfword holds the next ticket number

PLDW[R1] ; preload into cache in unique state
Loop1
LDAEX R5, [R1] ; read current and next
ADD R5, R5, #0x10000 ; increment the next number
STREX R6, R5, [R1] ; and update the value
CMP R6, #0 ; did the exclusive pass
BNE Loop1 ; retry if not
CMP R5, R5, ROR #16 ; is the current ticket ours
BEQ block_start
Loop2
LDAH R6, [R1] ; read current value
CMP R6, R5, LSR #16 ; compare it with our allocated ticket
BNE Loop2 ; retry (spin) if it is not the same
block_start
```

AArch64

```
Px
    ; X1 holds 2 16 bit quantities
    ; the lower halfword holds the current ticket number
    ; the higher halfword holds the next ticket number

    PRFM PSTL1KEEP, [X1] ; preload into cache in unique state
Loop1
    LDAXR W5, [X1] ; read current and next
    ADD W5, W5, #0x10000 ; increment the next number
    STXR W6, W5, [X1] ; and update the value
    CBNZ W6, Loop1 ; did the exclusive pass - retry if not

    AND W6, W5, #0xFFFF
    CMP W6, W5, LSR #16 ; is the current ticket ours
    B.EQ block_start
Loop2
    LDARH W6, [X1] ; read current value
    CMP W6, W5, LSR #16 ; compare it with the our allocated ticket
    B.NE Loop2 ; retry (spin) if it isn't the same
block_start
```

Releasing the ticket lock simply involves incrementing the current ticket number, that is still assumed to be in R3, and doing a Store-Release:

AArch32

```
ADD R6, R6, #1
STLH R6, [R1]
```

AArch64

```
ADD W6, W6, #1
STLRH W6, [X1]
```

K9.3.4 Use of Wait For Event (WFE) and Send Event (SEV) with locks

The ARMv8 architecture can use the Wait For Event mechanism to minimise the energy cost of polling variables by putting the PE into a low power state, suspending execution, until an asynchronous exception or an explicit event is seen by that PE. In ARMv8, the event can be generated as a result of clearing the global monitor, so removing the need for a DSB barrier or an explicit send event message.

This can be used with simple locks or with ticket locks.

Simple lock

The following is an example of lock acquire code using WFE:

AArch32

```
Px
    PLDW[R1] ; preload into cache in unique state
Loop
    LDAEX R5, [R1] ; read lock with acquire
    CMP R5, #0 ; check if 0
    WFENE ; sleep if the lock is held
    STREXEQ R5, R0, [R1] ; attempt to store new value
    CMPEQ R5, #0 ; test if store succeeded
    BNE Loop ; retry if not
```

AArch64

Px

```
    SEVL                ; invalidates the WFE on the first loop iteration
    PRFM PSTL1KEEP, [X1] ; allocate into cache in unique state
Loop
    WFE
    LDAXR W5, [X1]      ; read lock with acquire
    CBNZ W5, Loop       ; check if 0
    STXR W5, W0, [X1]   ; attempt to store new value
    CBNZ W5, Loop       ; test if store succeeded and retry if not

    ; loads and stores in the critical region can now be performed
```

And the following is an example of lock release code:

AArch32

Px

```
    ; loads and stores in the critical region
    MOV R0, #0
    STL R0, [R1]        ; clear the lock
```

AArch64

Px

```
    ; loads and stores in the critical region
    STLR WZR, [X1]     ; clear the lock
```

Ticket lock

In the Ticket lock case, the Load-Exclusive instruction can be used to move the monitor into the exclusive state for the express purpose of creating an event when the monitor changes state:

AArch32

Px

```
    ; R1 holds 2 16 bit quantities
    ; the lower halfword holds the current ticket number
    ; the higher halfword holds the next ticket number

    PLDW[R1]           ; preload into cache in unique state
Loop1
    LDAEX R5, [R1]     ; read current and next
    ADD R5, R5, #0x10000 ; increment the next number
    STREX R6, R5, [R1] ; and update the value
    CMP R6, #0         ; did the exclusive pass
    BNE Loop           ; retry if not
    CMP R5, R5, ROR #16 ; is the current ticket ours
    BEQ block_start
    SEVL
Loop2
    WFE                ; wait if there has not been a change to the count since last
                       ; read
    LDAEXH R6, [R1]    ; check the current count
    CMP R6, R5, LSR #16 ; check if it is equal
    BNE Loop2
block_start
```

AArch64

Px

```
; X1 holds 2 16 bit quantities
; the lower halfword holds the current ticket number
; the higher halfword holds the next ticket number

PRFM PSTL1KEEP, [X1] ; preload into cache in unique state
Loop1
LDAXR W5, [X1] ; read current and next
ADD W5, W5, #0x10000 ; increment the next number
STXR W6, W5, [X1] ; and update the value
CBNZ W6, Loop1 ; did the exclusive pass - retry if not

AND W6, W5, 0xFFFF
CMP W6, W5, LSR #16 ; is the current ticket ours
B.EQ block_start
SEVL

WFE
LDAXRH W6, [X1] ; read current value
CMP W6, W5, LSR #16 ; compare it with our allocated ticket
B.NE Loop2 ; retry (spin) if it is not the same
block_start
```

K9.4 Using a mailbox to send an interrupt

In some message passing systems, it is common for one observer to update memory and then notify a second observer of the update by sending an interrupt, using a mailbox.

Although a memory access might be made to initiate the sending of the mailbox interrupt, a DSB instruction is required to ensure the completion of previous memory accesses.

Therefore, the following sequence is required to ensure that P2 observes the updated value:

AArch32

P1

```
STR R5, [R1]          ; message stored to shared memory location
DSB ST
STR R0, [R4]          ; R4 contains the address of a mailbox
```

P2

```
; interrupt service routine
LDR R5, [R1]
```

AArch64

P1

```
STR W5, [X1]          ; message stored to shared memory location
DSB ST
STR W0, [X4]          ; R4 contains the address of a mailbox
```

P2

```
; interrupt service routine
LDR W5, [X1]
```

K9.5 Cache and TLB maintenance instructions and barriers

The following sections describe the use of barriers with cache and TLB maintenance instructions:

- [Data cache maintenance instructions](#).
- [Instruction cache maintenance instructions on page K9-6231](#).
- [TLB maintenance instructions and barriers on page K9-6234](#).

K9.5.1 Data cache maintenance instructions

The following sections describe the use of barriers with data cache maintenance instructions:

- [Message passing to non-caching observers](#).
- [Multiprocessing message passing to non-caching observers on page K9-6228](#).
- [Invalidating DMA buffers, non-functional example on page K9-6229](#).
- [Invalidating DMA buffers, functional example with single PE on page K9-6229](#).
- [Invalidating DMA buffers, functional example with multiple coherent PEs on page K9-6230](#).

Message passing to non-caching observers

The ARMv8 architecture requires the use of DMB instructions to ensure the ordering of data cache maintenance instructions and their effects. The Load-Acquire and Store-Release instructions have no effect on cache maintenance instruction. This means the following message passing approaches can be used when communicating between caching observers and non-caching observers:

AArch32

P1

```
STR R5, [R1]           ; updates data (assumed to be in P1 cache)
DCCMVAC R1             ; cleans cache to point of coherency
DMB                   ; ensures effects of the clean will be observed before the
                       ; flag is set
STR R0, [R4]          ; sends flag to external agent (Non-cacheable location)
```

E1

```
WAIT_ACQ ([R4] == 1) ; waits for the flag (with order)
LDR R5, [R1]         ; reads the data
```

AArch64

P1

```
STR W5, [X1]          ; updates data (assumed to be in P1 cache)
DC CVAC, X1           ; cleans cache to point of coherency
DMB ISH               ; ensures effects of the clean will be observed before the
                       ; flag is set
STR W0, [X4]          ; sends flag to external agent (Non-cacheable location)
```

E1

```
WAIT_ACQ ([X4] == 1) ; waits for the flag (with order)
LDR W5, [X1]         ; reads the data
```

In this example, it is required that E1:R5==0x55.

Multiprocessing message passing to non-caching observers

The broadcast nature of the cache maintenance instructions combined with properties of barriers, means that the message passing principle for non-caching observers is:

AArch32

P1

```
STR R5, [R1]      ; updates data (assumed to be in P1 cache)
STL R0, [R2]      ; sends a flag for P2 (ordered by the store release)
```

P2

```
WAIT ([R2] == 1) ; waits for P1 flag
DMB              ; ensures cache clean is observed after P1 flag is observed
DCCMVAC R1       ; cleans cache to point of coherency - will clean P1 cache
DMB              ; ensures effects of the clean will be observed before the
                 ; flag to E1 is set
STR R0, [R4]     ; sends flag to E1
```

E1

```
WAIT_ACQ ([R4] == 1) ; waits for P2 flag (ordered)
LDR R5, [R1]         ; reads data
```

AArch64

P1

```
STR W5, [X1]      ; updates data (assumed to be in P1 cache)
STLR W0, [X2]     ; sends a flag for P2 (ordered)
```

P2

```
WAIT ([X2] == 1) ; waits sfor P1 flag
DMB SY           ; ensure cache clean is observed after P1 flag is observed
DC CVAC, X1      ; cleans cache to point of coherency, will clean P1 cache
DMB SY           ; ensures effects of the clean will be observed before the
                 ; flag to E1 is set
STR W0, [X4]     ; sends flag to E1
```

E1

```
WAIT_ACQ ([X4] == 1) ; waits for P2 flag
LDR W5, [X1]         ; reads data
```

In this example, it is required that E1:R5==0x55. The clean operation executed by P2 affects the data location in the P1 cache. The cast-out from the P1 cache is guaranteed to be observed before P2 updates [R4].

————— Note —————

The cache maintenance instructions are not ordered by the Load-Acquire and Store-Release instructions.

Invalidate DMA buffers, non-functional example

The basic scheme for communicating with an external observer that is a process that passes data in to a Cacheable memory region must take account of the architectural requirement that regions with a Normal Cacheable attribute can be allocated into a cache at any time, for example as a result of speculation. The following example shows this possibility:

AArch32

P1

```
DCIMVAC R1      ; ensures cache is not dirty. A clean operation could be used
                ; but as the DMA will subsequently overwrite this region an
                ; invalidate operation is sufficient and usually more efficient
DMB             ; ensures cache invalidation is observed before the next store
                ; is observed
STR R0, [R3]    ; sends flag to external agent
WAIT_ACQ ([R4]==1) ; waits for a different flag from an external agent
LDR R5, [R1]
```

E1

```
WAIT ([R3] == 1) ; waits for flag
STR R5, [R1]     ; stores new data
STL R0, [R4]     ; sends a flag
```

AArch64

P1

```
DC IVAC, X1     ; ensure cache is not dirty. A clean operation could be used
                ; but as the DMA will subsequently overwrite this region an
                ; invalidate operation is sufficient and usually more efficient
DMB SY         ; ensures cache invalidation is observed before the next store
                ; is observed
STR W0, [X3]    ; sends flag to external agent
WAIT_ACQ ([X4]==1) ; waits for a different flag from an external agent
LDR W5, [X1]
```

E1

```
WAIT ([X3] == 1) ; waits for flag
STR W5, [X1]     ; stores new data
STLR W0, [X4]    ; sends a flag
```

If a speculative access occurs, there is no guarantee that the cache line containing [R1] is not brought back into the cache after the cache invalidation, but before [R1] is written by E1. Therefore, the result P1:R5=0 is permissible.

Invalidate DMA buffers, functional example with single PE

AArch32

P1

```
DCIMVAC R1      ; ensures cache is not dirty. A clean operation could be used
                ; but as the DMA will subsequently overwrite this region an
                ; invalidate operation is sufficient and usually more efficient
DMB             ; ensures cache invalidation is observed before the next store
                ; is observed
STR R0, [R3]    ; sends flag to external agent
WAIT ([R4]==1) ; waits for a different flag from an external agent
DMB            ; ensures that cache invalidate is observed after the flag
                ; from external agent is observed
DCIMVAC R1      ; ensures cache discards stale copies before use
LDR R5, [R1]
```

E1

```
WAIT ([R3] == 1) ; waits for flag
```

```
STR R5, [R1]      ; stores new data
STL R0, [R4]      ; sends a flag
```

AArch64

P1

```
DC IVAC, X1      ; ensures cache is not dirty. A clean operation could be used
                  ; but as the DMA will subsequently overwrite this region an
                  ; invalidate operation is sufficient and usually more efficient
DMB SY           ; ensures cache invalidation is observed before the next store
                  ; is observed
STR W0, [X3]     ; sends flag to external agent
WAIT ([X4]==1)   ; waits for a different flag from an external agent
DMB SY           ; ensures that cache invalidate is observed after the flag
                  ; from external agent is observed
DC IVAC, X1     ; ensures cache discards stale copies before use
LDR W5, [X1]
```

E1

```
WAIT ([X3] == 1) ; waits for flag
STR W5, [X1]     ; stores new data
STLR W0, [X4]    ; sends a flag
```

In this example, the result P1:R5 == 0x55 is required. Including a cache invalidation after the store by E1 to [R1] is observed ensures that the line is fetched from external memory after it has been updated.

Invalidating DMA buffers, functional example with multiple coherent PEs

The broadcasting of cache maintenance instructions, and the use of DMB instructions to ensure their observability, means that the previous example extends naturally to a multiprocessor system. Typically this requires a transfer of ownership of the region that the external observer is updating.

AArch32

P0

```
(Use data from [R1], potentially using [R1] as scratch space)
STL R0, [R2]      ; signals release of [R1]
WAIT_ACQ ([R2] == 0) ; waits for new value from DMA
LDR R5, [R1]
```

P1

```
WAIT ([R2] == 1) ; waits for release of [R1] by P0
DCIMVAC R1      ; ensures caches are not dirty, an invalidate is sufficient
DMB
STR R0, [R3]    ; requests new data for [R1]
WAIT ([R4] == 1) ; waits for new data
DMB
DCIMVAC R1      ; ensures caches discard stale copies before use
DMB
MOV R0, #0
STR R0, [R2]    ; signals availability of new [R1]
```

E1

```
WAIT ([R3] == 1) ; waits for new data request
STR R5, [R1]     ; sends new [R1]
DMB [ST]
STR R0, [R4]     ; indicates that new data is available to P1
```

AArch64

P0

```
(Use data from [X1], potentially using [X1] as scratch space)
STLR W0, [X2]    ; signals release of [X1]
```

```
WAIT_ACQ ([X2] == 0) ; waits for new value from DMA
LDR W5, [X1]
```

P1

```
WAIT ([X2] == 1) ; waits for release of [R1] by P0
DC IVAC, X1 ; ensures caches are not dirty, an invalidate is sufficient
DMB SY
STR W0, [X3] ; requests new data for [R1]
WAIT ([X4] == 1) ; waits for new data
DMB SY
DCIMVAC X1 ; ensures caches discard stale copies before use
DMB SY
STR WZR, [X2] ; signals availability of new [R1]
```

E1

```
WAIT ([X3] == 1) ; waits for new data request
STR W5, [X1] ; sends new [R1]
STR W0, [X4] ; indicates new data is available to P1
```

In this example, the result P0:R5 == 0x55 is required. The DMB issued by P1 after the first data cache invalidation ensures that effect of the cache invalidation on P0 is seen by E1 before the store by E1 to [R1]. The DMB issued by P1 after the second data cache invalidation ensures that its effects are seen before the store of 0 to the semaphore location in [R2].

K9.5.2 Instruction cache maintenance instructions

The following sections describe the use of barriers with instruction cache maintenance instructions:

- [Ensuring the visibility of updates to instructions for a uniprocessor.](#)
- [Ensuring the visibility of updates to instructions for a multiprocessor on page K9-6232.](#)

Ensuring the visibility of updates to instructions for a uniprocessor

On a single PE, the agent that causes instruction fetches, or instruction cache linefills, is a separate memory system observer from the agent that causes data accesses. Therefore, any operations to invalidate the instruction cache can rely only on seeing updates to memory that are complete. This must be ensured by the use of a DSB instruction.

Also, instruction cache maintenance instructions are only guaranteed to complete after the execution of a DSB, and an ISB is required to discard any instructions that might have been prefetched before the instruction cache invalidation completed. Therefore, on a uniprocessor, to ensure the visibility of an update to code and to branch to it, the following sequence is required:

AArch32

P1

```
STR R11, [R1] ; R11 contains a new instruction to be stored in program memory
DCCMVAU R1 ; clean to PoU makes the new instruction visible to the instruction cache
DSB
ICIMVAU R1 ; ensures instruction cache/branch predictor discards stale data
BPIMVA R1
DSB ; ensures completion of the invalidation
ISB ; ensures instruction fetch path sees new instruction cache state
BX R1
```

In AArch64 state, the branch predictor maintenance is not required.

AArch64

P1

```
STR W11, [X1] ; W11 contains a new instruction to be stored in program memory
DC CVAU, X1 ; clean to PoU makes the new instruction visible to instruction cache
DSB ISH
IC IVAU, X1 ; ensures instruction cache/branch predictor discards stale data
```

```
DSB ISH          ; ensures completion of the invalidation
ISB              ; ensures instruction fetch path sees new instruction cache state
BR X1
```

———— **Note** ————

Where the changes to the instructions span multiple cache lines, then the data cache and instruction cache maintenance instructions can be duplicated to cover each of the lines to be cleaned and to be invalidated.

Ensuring the visibility of updates to instructions for a multiprocessor

The ARMv8 architecture requires a PE that executes an instruction cache maintenance instruction to execute a DSB instruction to ensure completion of the maintenance operation. This ensures that the cache maintenance instruction is complete on all PEs in the Inner Shareable shareability domain.

An ISB is not broadcast, and so does not affect other PEs. This means that any other PE must perform its own ISB synchronization after it knows that the update is visible, if it is necessary to ensure its synchronization with the update. The following example shows how this might be done:

AArch32

P1

```
STR R11, [R1]    ; R11 contains a new instruction to be stored in program memory
DCCMVAU R1      ; clean to PoU makes the new instruction visible to the instruction cache
DSB             ; ensures completion of the clean on all PEs
ICIMVAU R1      ; ensures instruction cache discards stale data
BPIMVA R        ; ensures branch predictor discards stale data
DSB             ; ensures completion of the instruction cache and branch predictor
                ; invalidation on all PEs
STR R0, [R2]    ; sets flag to signal completion
ISB             ; synchronizes context on this PE
BX R1           ; branches to new code
```

P2-Px

```
WAIT ([R2] == 1) ; waits for flag signalling completion
ISB              ; synchronizes context on this PE
BX R1           ; branches to new code
```

AArch64

P1

```
STR X11, [X1]   ; X11 contains a new instruction to be stored in program memory
DC CVAU, X1     ; clean to PoU makes the new instruction visible to the instruction cache
DSB ISH        ; ensures completion of the clean on all PEs
IC IVAU, X1     ; ensures instruction cache/branch predictor discards stale data
DSB ISH        ; ensures completion of the instruction cache/branch predictor
                ; invalidation on all PEs
STR W0, [X2]   ; sets flag to signal completion
ISB            ; synchronizes context on this PE
BR R1          ; branches to new code
```

P2-Px

```
WAIT ([X2] == 1) ; waits for flag signalling completion
ISB              ; synchronizes context on this PE
BR X1           ; branches to new code
```

Nonfunctional approach

The following sequence does not have the same effect, because a DSB is not required to complete the instruction cache maintenance instructions that other PEs issue:

AArch32

P1

```

STR R11, [R1]      ; R11 contains a new instruction to be stored in program memory
DCCMVAU R1        ; clean to PoU makes the new instruction visible to the instruction cache
DSB               ; ensures completion of the clean on all PEs
ICIMVAU R1        ; ensures instruction cache discards stale data
BPIMVA R1         ; ensures branch predictor discards stale data
DMB               ; ensures ordering of the store after the invalidation
                  ; DOES NOT guarantee completion of instruction cache/branch
                  ; predictor on other PEs
STR R0, [R2]      ; sets flag to signal completion
DSB               ; ensures completion of the invalidation on all PEs
ISB               ; synchronizes context on this PE
BX R1             ; branches to new code

```

P2-Px

```

WAIT ([R2] == 1)  ; waits for flag signalling completion
DSB               ; this DSB does not guarantee completion of P1
                  ; ICIMVAU/BPIMVA
ISB
BX R1

```

AArch64

P1

```

STR W11, [X1]     ; W11 contains a new instruction to be stored in program memory
DC CVAU, X1       ; clean to PoU makes the new instruction visible to instruction cache
DSB ISH           ; ensures completion of the clean on all PEs
IC IVAU, X1       ; ensures instruction cache/branch predictor discards stale data
DMB ISH           ; ensures ordering of the store after the invalidation
                  ; DOES NOT guarantee completion of instruction cache/branch
                  ; predictor on other PEs
STR W0, [X2]      ; sets flag to signal completion
DSB ISH           ; ensures completion of the invalidation on all PEs
ISB               ; synchronizes context on this PE
BR X1             ; branches to new code

```

P2-Px

```

WAIT ([X2] == 1)  ; waits for flag signalling completion
DSB ISH           ; this DSB does not guarantee completion of P1
                  ; ICIMVAU/BPIMVA
ISB
BR X1

```

In this example, P2...Px might not see the updated region of code at R1.

K9.5.3 TLB maintenance instructions and barriers

The following sections describe the use of barriers with TLB maintenance instructions:

- [Ensuring the visibility of updates to translation tables for a uniprocessor.](#)
- [Ensuring the visibility of updates to translation tables for a multiprocessor on page K9-6235.](#)
- [Paging memory in and out on page K9-6235.](#)
- [Using break-before-make when updating translation table entries on page K9-6236.](#)

Ensuring the visibility of updates to translation tables for a uniprocessor

On a single PE, the agent that causes translation table walks is a separate memory system observer from the agent that causes data accesses. Therefore, any operations to invalidate the TLB can only rely on seeing updates to memory that are complete. This must be ensured by the use of a DSB instruction.

The ARMv8 architecture requires that translation table walks look in the data or unified caches at L1, so such systems do not require data cache cleaning.

After the translation tables update, any old copies of entries that might be held in the TLBs must be invalidated. This operation is only guaranteed to affect all instructions, including instruction fetches and data accesses, after the execution of a DSB and an ISB. Therefore, the code for updating a translation table entry is:

AArch32

P1

```
STR R11, [R1]      ; updates the translation table entry
DSB                ; ensures visibility of the update to translation table walks
TLBIMVA R10
BPIALL
DSB                ; ensures completion of the BP and TLB invalidation
ISB                ; synchronises context on this PE
; new translation table entry can be relied upon at this point and all accesses
; generated by this observer using
; the old mapping have been completed
```

AArch64

P1

```
STR X11, [X1]     ; updates the translation table entry
DSB ISH           ; ensures visibility of the update to translation table walks
TLBI VAE1, X10    ; assumes we are in the EL1
DSB ISH           ; ensures completion of the TLB invalidation
ISB               ; synchronise context on this PE
; new translation table entry can be relied upon at this point and all accesses
; generated by this observer using
; the old mapping have been completed
```

Importantly, by the end of this sequence, all accesses that used the old translation table mappings have been observed by all observers.

An example of this is where a translation table entry is marked as invalid. Such a system must provide a mechanism to ensure that any access to a region of memory being marked as invalid has completed before any action is taken as a result of the region being marked as invalid.

Ensuring the visibility of updates to translation tables for a multiprocessor

The same code sequence can be used in a multiprocessing system. The ARMv8 architecture requires a PE that executes a TLB maintenance instruction to execute a DSB instruction to ensure completion of the maintenance operation. This ensures that the TLB maintenance instruction is complete on all PEs in the Inner Shareable shareability domain.

The completion of a DSB that completes a TLB maintenance instruction ensures that all accesses that used the old mapping have completed.

AArch32

P1

```

STR R11, [R1]      ; updates the translation table entry
DSB                ; ensures visibility of the update to translation table walks
TLBIMVAIS R10
BPIALLIS
DSB                ; ensures completion of the BP and TLB invalidation
ISB                ; Note ISB is not broadcast and must be executed locally
                  ; on other PEs
; new translation table entry can be relied upon at this point and all accesses
; generated by any observers affected by the broadcast TLBIMVAIS operation using
; the old mapping have been completed

```

AArch64

P1

```

STR X11, [X1]      ; updates the translation table entry
DSB ISH            ; ensures visibility of the update to translation table walks
TLBI VAE1IS, X10
DSB ISH            ; ensures completion of the TLB invalidation
ISB                ; Note ISB is not broadcast and must be executed locally
                  ; on other PEs
; new translation table entry can be relied upon at this point and all accesses
; generated by any observers affected by the broadcast TLBIMVAIS operation using
; the old mapping have been completed

```

The completion of the TLB maintenance instruction is guaranteed only by the execution of a DSB by the observer that performed the TLB maintenance instruction. The execution of a DSB by a different observer does not have this effect, even if the DSB is known to be executed after the TLB maintenance instruction is observed by that different observer.

Paging memory in and out

In a multiprocessor system there is a requirement to ensure the visibility of translation table updates when paging regions of memory into RAM from a backing store. This might, or might not, also involve paging existing locations in memory from RAM to a backing store. In such situations, the operating system selects one or more pages of memory that might be in use but are suitable to discard, with or without copying to a backing store, depending on whether or not the region of memory is writable. Disabling the translation table mappings for a page, and ensuring the visibility of that update to the translation tables, prevents agents accessing the page.

For this reason, it is important that the DSB that is performed after the TLB invalidation ensures that no other updates to memory using those mappings are possible.

An example sequence for the paging out of an updated region of memory, and the subsequent paging in of memory, is as follows:

AArch32

P1

```

STR R11, [R1]      ; updates the translation table for the region being paged out
DSB                ; ensures visibility of the update to translation table walks
TLBIMVAIS R10      ; invalidates the old entry
DSB                ; ensures completion of the invalidation on all PEs

```

```
ISB          ; ensures visibility of the invalidation
BL SaveMemoryPageToBackingStore
BL LoadMemoryFromBackingStore
DSB          ; ensures completion of the memory transfer (this could be part of
              ; LoadMemoryFromBackingStore)
ICIAILLUIS   ; also invalidates the branch predictor
STR R9, [R1] ; creates a new translation table entry with a new mapping
DSB          ; ensures completion of the instruction cache
              ; and branch predictor invalidation
              ; AND ensures visibility of the new translation table mapping
ISB          ; ensures synchronisation of this instruction stream
```

AArch64

P1

```
STR X11, [X1] ; updates the translation table for the region being paged out
DSB ISH       ; ensures visibility of the update to translation table walks
TLBI VAE1IS, X10 ; invalidates the old entry
DSB ISH       ; ensures completion of the invalidation on all PEs
ISB          ; ensures visibility of the invalidation
BL SaveMemoryPageToBackingStore
BL LoadMemoryFromBackingStore
DSB ISH       ; ensures completion of the memory transfer (this could be part of
              ; LoadMemoryFromBackingStore)
IC IALLUIS   ; also invalidates the branch predictor
STR X9, [X1] ; creates a new translation table entry with a new mapping
DSB ISH       ; ensures completion of the instruction cache
              ; and branch predictor invalidation
              ; AND ensures visibility of the new translation table mapping
ISB          ; ensures synchronisation of this instruction stream
```

This example assumes the memory copies are performed by an observer that is coherent with the caches of PE P1. This observer might be P1 itself, using a specific paging mapping. For clarity, the example omits the functional descriptions of `SaveMemoryPageToBackingStore` and `LoadMemoryFromBackingStore`. `LoadMemoryFromBackingStore` is required to ensure that the memory updates that it makes are visible to instruction fetches.

In this example, the use of `ICIAILLUIS` in AArch32 state and `IC IALLUIS` in AArch64 state to invalidate the entire instruction cache is a simplification, that might not be optimal for performance. An alternative approach involves invalidating all of the lines in the caches using `ICIMVAU` in AArch32 state and `IC IVAU` operations in AArch64 state. This invalidation must be done when the mapping used for the `ICIMVAU` and `IC IVAU` operations is valid but not executable.

Using break-before-make when updating translation table entries

The ARM Architecture requires that reads to the same location are observed in order, and since application level software relies on this behavior, the operating system needs to maintain this illusion when it is changing a virtual to physical address mapping for a location, as is the case with copy on write or other memory management techniques. This illusion can be maintained provided that the software uses a break-before-make sequence when updating translation table entries whenever multiple threads of execution can use the same translation tables and the change to the translation entries involves any of:

- Changing the memory type.
- Changing the cacheability attributes
- Changing the output address (OA), if the OA of at least one of the old translation table entry and the new translation table entry is writable.

The architecture requires use of a break-before make sequence in these situations, see [Using break-before-make when updating translation table entries on page D4-2120](#) for more information. However, if software did not use a break-before-make approach, an implementation might give a result that would occur if the two reads to the same virtual address did not occur in program order. An example of such an occurrence would be an implementation of copy-on-write, where one PE is performing two reads to the same virtual address at the same time as a second PE,

running code associated with the operating system, is copying the data from one physical location that is mapped to by that virtual address, where the page was mapped as read-only, to a different physical location which will be mapped as read-write.

If the operating system changed the address mapping without going through an invalid entry, then it would be possible for a third PE to perform a write to the location that would be seen by the first load by the first PE, and not seen by the second load by the same PE.

The required break-before-make code sequence in this case is:

AArch32

P1

```

; R1, R2 contain an invalid translation table entry (that is, one with bit[0] == 0)
; R3 contains the address of the translation table entry
; R4 contains the Virtual Address and ASID of the VA being remapped
; R5, R6 contain the new valid translation table entry
STRD R1, R2, [R3]      ; stores invalid entry
DSB ISH                ; ensures visibility of the update to translation table walks
TLBIMVAIS R4          ; invalidates the old entry
DSB ISH                ; ensures completion of the invalidation on all PEs
ICIALLUIS             ; also invalidates the branch predictor
STRD R5, R6, [R3]     ; store new mapping
DSB ISH                ; ensures visibility of the update to translation table walks
ISB                    ; ensures synchronisation of this instruction stream

```

———— Note ————

This example shows an update to an entry in a translation table that is using the long-descriptor format.

AArch64

P1

```

; X1 contains an invalid translation table entry (that is, one with bit[0] == 0)
; X2 contains the address of the translation table entry
; X3 contains the Virtual Address and ASID of the VA being remapped
; X4 contains the new valid translation table entry
STR X1, [X2]          ; stores invalid entry
DSB ISH                ; ensures visibility of the update to translation table walks
TLBI VAE1IS, X3      ; invalidates the old entry
DSB ISH                ; ensures completion of the invalidation on all PEs
IC IALLUIS            ; also invalidates the branch predictor
STR X4, [X2]         ; store new mapping
DSB ISH                ; ensures visibility of the update to translation table walks
ISB                    ; ensures synchronisation of this instruction stream

```

If this sequence is correctly followed, then the architecture guarantees that the loads to a virtual address being remapped will be seen in the correct order.

The instruction cache maintenance is only required if the mapping from input address to output address has been changed as part of the change of the translation table entries, and the memory being moved is executable. In this example, the use of ICIALLUIS in AArch32 state and IC IALLUIS in AArch64 state to invalidate the entire instruction cache is a simplification, that might not be optimal for performance. An alternative approach involves invalidating all of the lines in the caches using ICIMVAU in AArch32 state, and IC IVAU in AArch64 state. This invalidation must be done when the mapping used for the ICIMVAU and IC IVAU operations is valid but not executable.

K9.5.4 Ordering of Memory-mapped device control with payloads

With a Memory-mapped peripheral, such as a DMA, which can also access memory for its own use, it is common to have control or status registers which are Memory-mapped. These registers need to be accessed in an ordered manner with respect to the data that the Memory-mapped peripheral is handling.

Two simple examples of this are:

- When a processing element is writing a buffer of data, and then writing to a control register in the DMA peripheral to start that peripheral to access the buffer of data.
- When a DMA peripheral has written to a buffer of data in memory, and the processing element is reading a status register to determine that the DMA transfer has completed, and then is reading the data.

For the case of the processing element writing a buffer of data, before starting the DMA peripheral, the ordering requirements between the stores to the data buffer and the stores to the Memory-mapped peripheral can be met by the insertion of a DSB <domain> instruction between these sets of accesses as this ensures the global observation of the stores before the DMA is started. This is shown by the following code:

AArch32

P1

```
STR R5, [R2]          ; data written to the data buffer
DSB
STR R0, [R4]          ; R4 contains the address of the DMA control register
```

AArch64

P1

```
STR W5, [X2]          ; data written to the data buffer
DSB <domain>
STR W0, [X4]          ; X4 contains the address of the DMA control register
```

For the case of DMA peripheral writing the data buffer and then setting a status register when those stores are complete (and so globally observed) and then having this status register polled by the processing element before the processing element reads the data buffer, the processing element must insert a DSB <domain> between the load that reads the status register, and the read of the buffer. A DMB, or load-acquire, is not sufficient as this problem is not solely concerned with observation order, since the polling read is actually a read of a status register at a slave, not the polling a data value that has been written by an observer.

For this case, the code is therefore:

AArch32

P1

```
WAIT ([R4] == 1)      ; R4 contains the address of the status register,
                      ; and the value '1' indicates completion of the DMA transfer
DSB
LDR R5, [R2]          ; reads data from the data buffer
```

AArch64

P1

```
WAIT ([X4] == 1)      ; X4 contains the address of the status register,
                      ; and the value '1' indicates completion of the DMA transfer
DSB <domain>
LDR W5, [X2]          ; reads data from the data buffer
```

K9.6 ARMv7 compatible approaches for ordering, using DMB and DSB barriers

The following sections describe the ARMv7 compatible approaches for ordering, using DMB and DSB barriers:

- [Simple ordering and barrier cases.](#)
- [Load-Exclusive, Store-Exclusive and barriers on page K9-6243.](#)
- [Using a mailbox to send an interrupt on page K9-6245.](#)
- [Cache and TLB maintenance instructions and barriers on page K9-6245.](#)

K9.6.1 Simple ordering and barrier cases

ARM implements a weakly consistent memory model for Normal memory. In general terms, this means that the order of memory accesses observed by other observers might not be the order that appears in the program, for either loads or stores.

This section includes examples of this.

Simple weakly consistent ordering example

P1

```
STR R5, [R1]
LDR R6, [R2]
```

P2

```
STR R6, [R2]
LDR R5, [R1]
```

In the absence of barriers, the result of P1: R6=0, P2: R5=0 is permissible.

Message passing

The following sections describe:

- [Weakly-ordered message passing problem.](#)
- [Message passing with multiple observers on page K9-6241.](#)

Weakly-ordered message passing problem

P1

```
STR R5, [R1]           ; sets new data
STR R0, [R2]           ; sends flag indicating data ready
```

P2

```
WAIT([R2]==1)         ; waits on flag
LDR R5, [R1]           ; reads new data
```

In the absence of barriers, an end result of P2: R5=0 is permissible.

Resolving by the addition of barriers

The addition of barriers, to ensure the observed order of the reads and the writes, ensures that data is transferred so that the result P2:R5==0x55 is guaranteed, as follows:

P1

```
STR R5, [R1]           ; sets new data
DMB [ST]               ; ensures all observers observe data before the flag
STR R0, [R2]           ; sends flag indicating data ready
```

```
P2
    WAIT([R2]==1)          ; waits on flag
    DMB                    ; ensures that the load of data is after the flag has been observed
    LDR R5, [R1]
```

Resolving by the use of barriers and address dependency

There is a rule within the ARM architecture that:

- Where the value returned by a read is used for computation of the virtual address of a subsequent read or write, then these two memory accesses are observed in program order.
 Where the value returned by a read is used for computation of the virtual address of a subsequent read or write, this is called an *address dependency*. An address dependency exists even if the value returned by the first read has no effect on the virtual address. This might occur if the value returned is masked off before it is used, or if it confirms a predicted address value that it might have changed.
 This restriction applies only when the data value returned by a read is used as a data value to calculate the address of a subsequent read or write. It does not apply if the data value returned by a read determines the condition flags values, and the values of the flags are used for condition code evaluation to determine the address of a subsequent read, either through conditional execution or the evaluation of a branch. This is called a *control dependency*.
 Where both a control and address dependency exist, the ordering behavior is consistent with the address dependency.

Table K9-1 shows examples of address dependencies, control dependencies, and an address and control dependency.

Table K9-1 Dependency examples

Address dependency		Control dependency		Address and control dependency ^a
(a)	(b)	(c)	(d)	(e)
LDR r1, [r0]	LDR r1, [r0]	LDR r1, [r0]	LDR r1, [r0]	LDR r1, [r0]
LDR r2, [r1]	AND r1, r1, #0	CMP r1, #55	CMP r1, #55	CMP r1, #0
	LDR r2, [r3, r1]	LDRNE r2, [r3]	MOVNE r4, #22	LDRNE r2, [r1]
			LDR r2, [r3, r4]	

a. The address dependency takes priority.

This means that the data transfer example of *Weakly-ordered message passing problem* on page K9-6239 can also be satisfied as shown in the following example:

```
P1
    STR R5, [R1]          ; sets new data
    DMB [ST]              ; ensures all observers observe data before the flag
    STR R0, [R2]          ; sends flag indicating data ready

P2
    WAIT([R2]==1)
    AND R12, R12, #0      ; R12 is destination of LDR in WAIT macro
    LDR R5, [R1, R12]     ; the load has an address dependency on R12
                          ; and so is ordered after the flag has been seen
```

The load of R5 by P2 is ordered with respect to the load from [R2] because there is an address dependency using R12. P1 uses a DMB to ensure that P2 does not observe the write of [R2] before the write of [R1].

Message passing with multiple observers

Where the ordering of Normal memory accesses is not resolved by the use of barriers or dependencies, then different observers might observe the accesses in a different order, as shown in the following example:

```
P1
    STR R5, [R1]           ; sets new data
    STR R0, [R2]           ; sends flag indicating data ready

P2
    WAIT([R2]==1)
    AND R12, R12, #0       ; R12 is destination of LDR in WAIT macro
    LDR R5, [R1, R12]     ; the load has an address dependency on R12
                           ; and so is ordered after the flag has been seen

P3
    WAIT([R2]==1)
    AND R12, R12, #0       ; R12 is destination of LDR in WAIT macro
    LDR R5, [R1, R12]     ; the load is address dependent on R12
                           ; and so is ordered after the flag has been seen
```

In this case, it is permissible for P2:R5 and P3:R5 to contain different values, because there is no order guaranteed between the two stores performed by P1.

Resolving by the addition of barriers

The addition of a barrier by P1, as shown in the following example, ensures the observed order of the writes, transferring data so that P2:R5 and P3:R5 both contain the value 0x55:

```
P1
    STR R5, [R1]           ; sets new data
    DMB [ST]              ; ensures all observers observe data before the flag
    STR R0, [R2]           ; sends flag indicating data ready

P2
    WAIT([R2]==1)
    AND R12, R12, #0       ; R12 is the destination of LDR in WAIT macro
    LDR R5, [R1, R12]     ; the load has an address dependency on R12
                           ; and so is ordered after the flag has been seen

P3
    WAIT([R2]==1)
    AND R12, R12, #0       ; R12 is the destination of LDR in WAIT macro
    LDR R5, [R1, R12]     ; the load has an address dependency on R12
                           ; and so is ordered after the flag has been seen
```

Address dependency with object construction

When accessing an object-oriented data structure, the address dependency rule means that barriers are not required, even when initializing the object:

```
P1
    STR R5, [R1, #offset]  ; sets new data in a field
    DMB [ST]              ; ensures all observers observe data before base address is updated
    STR R1, [R2]           ; updates base address

P2
    LDR R1, [R2]           ; reads for base address
    CMP R1, #0             ; checks if it is valid
    BEQ null_trap
```

```
LDR R5, [R1, #offset] ; uses base address to read field
```

If the null trap is not taken, it is required that P2:R5==0x55. This avoids P2 observing a partially constructed object from P1. Significantly, P2 does not require a barrier to ensure this behavior.

P1 requires a barrier to ensure the observed order of the writes by P1. In general, the impact of requiring a barrier during the construction phase is much less than the impact of requiring a barrier for every read access.

Posting a store before polling for acknowledgement

In the case where an observer stores to a location, and then polls for an acknowledge from a different observer, the weak ordering of the memory model can lead to a deadlock, as the following example shows:

```
P1
STR R0, [R2]
WAIT ([R3]==1)
```

```
P2
WAIT ([R2]==1)
STR R0, [R3]
```

In ARMv7 implementations that do not include the Multiprocessing Extensions, then this can deadlock because P2 might not observe the store by P1 in finite time. For ARMv7 implementations with the Multiprocessing Extensions and for ARMv8, this is not an issue as all stores must be observed by all observers within their shareability domain in finite time.

The addition of a DMB instruction prevents this deadlock in ARMv7 implementations that do not include the Multiprocessing Extensions:

```
P1
STR R0, [R2]
DMB
WAIT ([R3]==1)
```

```
P2
WAIT ([R2]==1)
STR R0, [R3]
```

The DMB executed by P1 ensures that P2 observes the store by P1 before it observes the load by P1. This ensures a timely completion.

The following example is a variant of the previous example, where the two observers poll the same memory location:

```
P1
STR R0, [R2]
WAIT ([R2]==2)
```

```
P2
WAIT ([R2]==1)
LDR R0, [R2]
ADD R0, R0, #1
STR R0, [R2]
```

In this example, the same deadlock can occur in ARMv7 implementations that do not include the Multiprocessing Extensions, because the architecture permits P1 to read the result of its own store to [R2] early, and continue doing so for an indefinite amount of time. The addition of a DMB instruction prevents this deadlock:

```
P1
STR R0, [R2]
DMB
WAIT ([R2]==2)
```

P2

```
WAIT ([R2]==1)
LDR R0, [R2]
ADD R0, R0, #1
STR R0, [R2]
```

WFE and WFI and barriers

The Wait For Event and Wait For Interrupt instructions permit the PE to suspend execution and enter a low-power state. A DSB barrier instruction is required if it is necessary to ensure that memory accesses made before the WFI or WFE are visible to other observers, unless some other mechanism has ensured this visibility. Examples of other mechanism that would guarantee the required visibility are the DMB described in [Posting a store before polling for acknowledgement on page K9-6242](#), or a dependency on a load.

The following example requires the DSB to ensure that the store is visible:

P1

```
STR R0, [R2]
DSB
Loop
WFI
B Loop
```

However, if the example in [Posting a store before polling for acknowledgement on page K9-6242](#) is extended to include a WFE, there is no risk of a deadlock. The extended example is:

P1

```
STR R0, [R2]
DMB
Loop
LDR R12, [R3]
CMP R12, #1
WFENE
BNE Loop
```

P2

```
WAIT ([R2]==1)
STR R0, [R3]
DSB
SEV
```

In this example:

- The DMB by P1 ensures that P2 observes the store by P1 before it observes the load by P1.
- The dependency of the WFE on the result of the load by P1 means that this load must complete before P1 executes the WFE.

For more information about SEV, see [Use of Wait For Event \(WFE\) and Send Event \(SEV\) with locks on page K9-6244](#).

K9.6.2 Load-Exclusive, Store-Exclusive and barriers

The Load-Exclusive and Store-Exclusive instructions, described in [Synchronization and semaphores on page B2-121](#), are predictable only with Normal memory. These instructions do not have any implicit barrier functionality. Therefore, any use of these instructions to implement locks of any type requires the addition of explicit barriers.

Acquiring a lock

A common use of Load-Exclusive and Store-Exclusive instructions is to claim a lock to permit entry into a critical region. This is typically performed by testing a lock variable that indicates 0 for a free lock and some other value, commonly 1 or an identifier of the process holding the lock, for a taken lock.

The lack of implicit barriers in the Load-Exclusive and Store-Exclusive instructions means that the mechanism requires a DMB instruction between acquiring a lock and making the first access to the critical region, to ensure that all observers observe the successful claim of the lock before they observe any subsequent loads or stores to the region. This example shows Px acquiring a lock:

```
Px
Loop
LDREX R5, [R1]      ; reads lock
CMP R5, #0          ; checks if 0
STREXEQ R5, R0, [R1] ; attempts to store new value
CMPEQ R5, #0        ; tests if store succeeded
BNE Loop            ; retries if not
DMB                 ; ensures that all subsequent accesses are observed after the
                    ; gaining of the lock is observed
                    ; loads and stores in the critical region can now be performed
```

Releasing a lock

The converse operation of releasing a lock does not require the use of Load-Exclusive and Store-Exclusive instructions, because only a single observer is able to write to the lock. However, often it is necessary for any observer to observe any memory updates, or any values that are loaded into memory, before they observe the release of the lock. Therefore, a DMB usually precedes the lock release, as the following example shows.

```
Px
                    ; loads and stores in the critical region
MOV R0, #0
DMB                 ; ensures all previous accesses are observed before the lock is cleared
STR R0, [R1]        ; clears the lock
```

Use of Wait For Event (WFE) and Send Event (SEV) with locks

The ARMv8 architecture includes Wait For Event and Send Event instructions, that can be executed to reduce the required number of iterations of a lock-acquire loop, or *spinlock*, to reduce power. The basic mechanism involves an observer that is in a spinlock executing a WFE instruction that suspends execution on that observer until an asynchronous exception or an explicit event, sent by some other observer using the SEV instruction, is seen by the suspended observer. An observer that holds the lock executes an SEV instruction to send an event after it has released the lock.

The Event signal is a non-memory communication, and therefore the memory update that releases the lock must be observable by all observers before the SEV instruction is executed and the event is sent. This requires the use of DSB instruction, rather than DMB.

Therefore, the following is an example of lock acquire code using WFE:

```
Px
Loop
LDREX R5, [R1]      ; reads lock
CMP R5, #0          ; checks if 0
WFE                 ; sleeps if the lock is held
STREXEQ R5, R0, [R1] ; attempts to store new value
CMPEQ R5, #0        ; tests if store succeeded
BNE Loop            ; retries if not
DMB                 ; ensures that all subsequent accesses are observed after the
                    ; gaining of the lock is observed
                    ; loads and stores in the critical region can now be performed
```

And the following is an example of lock release code using SEV:

```

Px
    ; loads and stores in the critical region
    MOV R0, #0
    DMB                ; ensures all previous accesses are observed before the lock is cleared
    STR R0, [R1]       ; clears the lock
    DSB                ; ensures completion of the store that cleared the lock before
                        ; sending the event
    SEV

```

K9.6.3 Using a mailbox to send an interrupt

In some message passing systems, it is common for one observer to update memory and then notify a second observer of the update by sending an interrupt, using a mailbox.

Although a memory access might be made to initiate the sending of the mailbox interrupt, a DSB instruction is required to ensure the completion of previous memory accesses.

Therefore, the following sequence is required to ensure that P2 observes the updated value:

```

P1
    STR R5, [R1]       ; message stored to shared memory location
    DSB [ST]
    STR R1, [R4]       ; R4 contains the address of a mailbox

P2
    ; interrupt service routine
    LDR R5, [R1]

```

———— **Note** ————

The DSB executed by P1 ensures global observation of the store to [R1]. The interrupt timing ensures that the code executed by P2 is executed after the global observation of the update to [R1], and therefore must see this update. In some implementations, this might be implemented by requiring that interrupts flush non-coherent buffers that hold speculatively loaded data.

K9.6.4 Cache and TLB maintenance instructions and barriers

The following sections describe the use of barriers with cache and TLB maintenance instructions:

- [Data cache maintenance instructions](#).
- [Instruction cache maintenance instructions](#) on page K9-6248.
- [TLB maintenance instructions and barriers](#) on page K9-6249.

Data cache maintenance instructions

The following sections describe the use of barriers with data cache maintenance instructions:

- [Message passing to non-caching observers](#).
- [Multiprocessing message passing to non-caching observers](#) on page K9-6246.
- [Invalidating DMA buffers, non-functional example](#) on page K9-6246.
- [Invalidating DMA buffers, functional example with single PE](#) on page K9-6247.
- [Invalidating DMA buffers, functional example with multiple coherent PEs](#) on page K9-6247.

Message passing to non-caching observers

The ARMv8 architecture requires the use of DMB instructions to ensure the ordering of data cache maintenance instructions and their effects. This means the following message passing approaches can be used when communicating between caching observers and non-caching observers:

```

P1

```

```
STR R5, [R1]           ; updates data (assumed to be in P1's cache)
DCCMVAC R1             ; cleans cache to point of coherency
DMB                    ; ensures effects of the clean will be observed before the flag is set
STR R0, [R4]           ; sends flag to external agent (Non-cacheable location)
```

E1

```
WAIT ([R4] == 1)       ; waits for the flag
DMB                    ; ensures that flag has been seen before reading data
LDR R5, [R1]           ; reads the data
```

In this example, it is required that E1:R5==0x55.

Multiprocessing message passing to non-caching observers

The broadcast nature of the cache maintenance instructions in ARMv8, and in ARMv7 implementations that include the Multiprocessing Extensions, combined with properties of barriers, means that the message passing principle for non-caching observers is:

P1

```
STR R5, [R1]           ; updates data (assumed to be in P1's cache)
DMB [ST]               ; ensures new data is observed before the flag to P2 is set
STR R0, [R2]           ; sends flag to P2
```

P2

```
WAIT ([R2] == 1)       ; waits for flag from P1
DMB                    ; ensures cache clean is observed after P1 flag is observed
DCCMVAC R1             ; cleans cache to point of coherency - this cleans the cache of P1
DMB                    ; ensures effects of the clean are observed before the flag to E1 is set
STR R0, [R4]           ; sends flag to E1
```

E1

```
WAIT ([R4] == 1)       ; waits for flag from P2
DMB                    ; ensures that flag has been observed before reading the data
LDR R5, [R1]           ; reads the data
```

In this example, it is required that E1:R5==0x55. The clean operation executed by P2 affects the data location in the P1 cache. The cast-out from the P1 cache is guaranteed to be observed before P2 updates [R4].

Invalidating DMA buffers, non-functional example

The basic scheme for communicating with an external observer that is a process that passes data in to a Cacheable memory region must take account of the architectural requirement that regions with a Normal Cacheable attribute can be allocated into a cache at any time, for example as a result of speculation. The following example shows this possibility:

P1

```
DCIMVAC R1             ; ensures caches are not dirty. A clean operation could be
                        ; used but the DMA overwrites this region so an invalidate operation
                        ; is sufficient and usually more efficient
DMB                    ; ensures cache invalidation is observed before the next store is observed
STR R0, [R3]           ; sends flag to external agent
WAIT ([R4]==1)         ; waits for a different flag from an external agent
DMB                    ; observes flag from external agent before reading new data. However [R1]
                        ; could have been brought into cache earlier
LDR R5, [R1]
```

E1

```
WAIT ([R3] == 1)       ; waits for flag
STR R5, [R1]           ; stores new data
DMB                    ;
STR R0, [R4]           ; sends a flag
```

If a speculative access occurs, there is no guarantee that the cache line containing [R1] is not brought back into the cache after the cache invalidation, but before [R1] is written by E1. Therefore, the result P1:R5=0 is permissible.

Invalidating DMA buffers, functional example with single PE

P1

```

DCIMVAC R1          ; ensures cache is not dirty. A clean operation could be
                    ; used but the DMA overwrites this region so an invalidate operation
                    ; is sufficient and usually more efficient
DMB                 ; ensures cache invalidation is observed before the next store is observed
STR R0, [R3]        ; sends flag to external agent
WAIT ([R4]==1)      ; waits for a different flag from an external agent
DMB                 ; ensures that cache invalidate is observed after the flag
                    ; from external agent is observed
DCIMVAC R1          ; ensures cache discards stale copies before use
LDR R5, [R1]

```

E1

```

WAIT ([R3] == 1)    ; waits for flag
STR R5, [R1]        ; stores new data
DMB [ST]
STR R0, [R4]        ; sends a flag

```

In this example, the result P1:R5 == 0x55 is required. Including a cache invalidation after the store by E1 to [R1] is observed ensures that the line is fetched from external memory after it has been updated.

Invalidating DMA buffers, functional example with multiple coherent PEs

The broadcasting of cache maintenance instructions, and the use of DMB instructions to ensure their observability, means that the previous example extends naturally to a multiprocessor system. Typically this requires a transfer of ownership of the region that the external observer is updating.

P0

```

(Use data from [R1], potentially using [R1] as scratch space)
DMB
STR R0, [R2]        ; signals release of [R1]
WAIT ([R2] == 0)    ; waits for new value from DMA
DMB
LDR R5, [R1]

```

P1

```

WAIT ([R2] == 1)    ; waits for release of [R1] by P0
DCIMVAC R1          ; ensures caches are not dirty, invalidate is sufficient
DMB
STR R0, [R3]        ; requests new data for [R1]
WAIT ([R4] == 1)    ; waits for new data
DMB
DCIMVAC R1          ; ensures caches discard stale copies before use
DMB
MOV R0, #0
STR R0, [R2]        ; signals availability of new [R1]

```

E1

```

WAIT ([R3] == 1)    ; waits for new data request
STR R5, [R1]        ; sends new [R1]
DMB [ST]
STR R0, [R4]        ; indicates new data available to P1

```

In this example, the result P0:R5 == 0x55 is required. The DMB issued by P1 after the first data cache invalidation ensures that effect of the cache invalidation on P0 is seen by E1 before the store by E1 to [R1]. The DMB issued by P1 after the second data cache invalidation ensures that its effects are seen before the store of 0 to the semaphore location in [R2].

Instruction cache maintenance instructions

The following sections describe the use of barriers with instruction cache maintenance instructions:

- [Ensuring the visibility of updates to instructions for a uniprocessor.](#)
- [Ensuring the visibility of updates to instructions for a multiprocessor.](#)

Ensuring the visibility of updates to instructions for a uniprocessor

On a single PE, the agent that causes instruction fetches, or instruction cache linefills, is a separate memory system observer from the agent that causes data accesses. Therefore, any operations to invalidate the instruction cache can rely only on seeing updates to memory that are complete. This must be ensured by the use of a DSB instruction.

Also, instruction cache maintenance instructions are only guaranteed to complete after the execution of a DSB, and an ISB is required to discard any instructions that might have been prefetched before the instruction cache invalidation completed. Therefore, on a uniprocessor, to ensure the visibility of an update to code and to branch to it, the following sequence is required:

P1

```
STR R11, [R1]           ; R11 contains a new instruction to store in program memory
DCCMVAU R1              ; clean to PoU makes new instructions visible to instruction cache
DSB                     ; ensures instruction cache and branch predictor discard stale data
ICIMVAU R1              ; ensures instruction cache and branch predictor discard stale data
BPIMVA R1               ; ensures instruction cache and branch predictor discard stale data
DSB                     ; ensures completion of the invalidation
ISB                     ; ensures instruction fetch path observes new instruction cache state
BX R1
```

Ensuring the visibility of updates to instructions for a multiprocessor

ARMv8, and an ARMv7 implementation that includes the Multiprocessing Extensions, requires a PE that executes an instruction cache maintenance instruction to execute a DSB instruction to ensure completion of the maintenance operation. This ensures that the cache maintenance instruction is complete on all PEs in the Inner Shareable shareability domain.

An ISB is not broadcast, and so does not affect other PEs. This means that any other PE must perform its own ISB synchronization after it knows that the update is visible, if it is necessary to ensure its synchronization with the update. The following example shows how this might be done:

P1

```
STR R11, [R1]           ; R11 contains a new instruction to store in program memory
DCCMVAU R1              ; clean to PoU makes new instructions visible to instruction cache
DSB                     ; ensures completion of the clean on all processors
ICIMVAU R1              ; ensures instruction cache/branch predictor discards stale data
BPIMVA R1               ; ensures instruction cache/branch predictor discards stale data
DSB                     ; ensures completion of the instruction cache and branch predictor
                       ; invalidation on all PEs
STR R0, [R2]            ; sets flag to signal completion
ISB                     ; synchronizes context on this PE
BX R1                   ; branches to new code
```

P2-Px

```
WAIT ([R2] == 1)        ; waits for flag signaling completion
ISB                     ; synchronizes context on this processor
BX R1                   ; branches to new code
```

Nonfunctional approach

The following sequence does not have the same effect, because a DSB is not required to complete the instruction cache maintenance instructions that other PEs issue:

P1

```
STR R11, [R1]           ; R11 contains a new instruction to store in program memory
DCCMVAU R1              ; clean to PoU makes new instructions visible to instruction cache
```

```

DSB                ; ensure completion of the clean on all PEs
ICIMVAU R1        ; ensure instruction cache/branch predictor discards stale data
BPIMVA R1
DMB                ; ensure ordering of the store after the invalidation
                  ; DOES NOT guarantee completion of instruction cache/branch
                  ; predictor on other PEs
STR R0, [R2]      ; sets flag to signal completion
DSB                ; ensures completion of the invalidation on all PEs
ISB                ; synchronizes context on this PE
BX R1              ; branches to new code
    
```

P2-Px

```

WAIT ([R2] == 1)   ; waits for flag signaling completion
DSB                ; this DSB does not guarantee completion of P1's ICIMVAU/BPIMVA
ISB
BX R1
    
```

In this example, P2...Px might not see the updated region of code at R1.

TLB maintenance instructions and barriers

The following sections describe the use of barriers with TLB maintenance instructions:

- [Ensuring the visibility of updates to translation tables for a uniprocessor.](#)
- [Ensuring the visibility of updates to translation tables for a multiprocessor on page K9-6250.](#)
- [Paging memory in and out on page K9-6250.](#)

Ensuring the visibility of updates to translation tables for a uniprocessor

On a single PE, the agent that causes translation table walks is a separate memory system observer from the agent that causes data accesses. Therefore, any operations to invalidate the TLB can only rely on seeing updates to memory that are complete. This must be ensured by the use of a DSB instruction.

In the ARMv8 architecture, and in an ARMv7 implementation that includes the Multiprocessing Extensions, translation table walks must look in the data or unified caches at L1, so such systems do not require data cache cleaning.

After the translation tables update, any old copies of entries that might be held in the TLBs must be invalidated. This operation is only guaranteed to affect all instructions, including instruction fetches and data accesses, after the execution of a DSB and an ISB. Therefore, the code for updating a translation table entry is:

P1

```

STR R11, [R1]      ; updates the translation table entry
DSB                ; ensures visibility of the update to translation table walks
TLBIMVA R10
BPIALL
DSB                ; ensures completion of the BP and TLB invalidation
ISB                ; synchronizes context on this PE
;
; new translation table entry can be relied upon at this point and all accesses
; generated by this observer using the old mapping have been completed
    
```

Importantly, by the end of this sequence, all accesses that used the old translation table mappings have been observed by all observers.

An example of this is where a translation table entry is marked as invalid. Such a system must provide a mechanism to ensure that any access to a region of memory being marked as invalid has completed before any action is taken as a result of the region being marked as invalid.

Ensuring the visibility of updates to translation tables for a multiprocessor

The same code sequence can be used in a multiprocessing system. In the ARMv8 architecture, and in an ARMv7 implementation that includes the Multiprocessing Extensions, a PE that executes a TLB maintenance instruction must execute a DSB instruction to ensure completion of the maintenance operation. This ensures that the TLB maintenance instruction is complete on all PEs in the Inner Shareable shareability domain.

The completion of a DSB that completes a TLB maintenance instruction ensures that all accesses that used the old mapping have completed.

P1

```
STR R11, [R1]          ; updates the translation table entry
DSB                    ; ensures visibility of the update to translation table walks
TLBIMVAIS R10
BPIALLIS
DSB                    ; ensures completion of the BP and TLB invalidation
ISB                    ; Note ISB is not broadcast and must be executed locally on other PEs
;
; new translation table entry can be relied upon at this point and all accesses generated by any
; observers affected by the broadcast TLBIMVAIS operation using the old mapping have completed
```

The completion of the TLB maintenance instruction is guaranteed only by the execution of a DSB by the observer that performed the TLB maintenance instruction. The execution of a DSB by a different observer does not have this effect, even if the DSB is known to be executed after the TLB maintenance instruction is observed by that different observer.

Paging memory in and out

In a multiprocessor system there is a requirement to ensure the visibility of translation table updates when paging regions of memory into RAM from a backing store. This might, or might not, also involve paging existing locations in memory from RAM to a backing store. In such situations, the operating system selects one or more pages of memory that might be in use but are suitable to discard, with or without copying to a backing store, depending on whether or not the region of memory is writable. Disabling the translation table mappings for a page, and ensuring the visibility of that update to the translation tables, prevents agents accessing the page.

For this reason, it is important that the DSB that is performed after the TLB invalidation ensures that no other updates to memory using those mappings are possible.

An example sequence for the paging out of an updated region of memory, and the subsequent paging in of memory, is as follows:

P1

```
STR R11, [R1]          ; updates the translation table for the region being paged out
DSB                    ; ensures visibility of the update to translation table walks
TLBIMVAIS R10          ; invalidates the old entry
DSB                    ; ensures completion of the invalidation on all processors
ISB                    ; ensures visibility of the invalidation
BL SaveMemoryPageToBackingStore
BL LoadMemoryFromBackingStore
DSB                    ; ensures completion of the memory transfer (this could be part of
; LoadMemoryFromBackingStore
ICIAILLUIS             ; also invalidates the branch predictor
STR R9, [R1]           ; creates a new translation table entry with a new mapping
DSB                    ; ensures completion of instruction cache and branch predictor invalidation
; and ensures visibility of the new translation table mapping
ISB                    ; ensures synchronization of this instruction stream
```

This example assumes the memory copies are performed by an observer that is coherent with the caches of PE P1. This observer might be P1 itself, using a specific paging mapping. For clarity, the example omits the functional descriptions of `SaveMemoryPageToBackingStore` and `LoadMemoryFromBackingStore`. `LoadMemoryFromBackingStore` is required to ensure that the memory updates that it makes are visible to instruction fetches.

In this example, the use of `ICIALUIS` to invalidate the entire instruction cache is a simplification, that might not be optimal for performance. An alternative approach involves invalidating all of the lines in the caches using `ICIMVAU` operations. This invalidation must be done when the mapping used for the `ICIMVAU` operations is valid but not executable.

Appendix K10

ARM Pseudocode Definition

This appendix provides a definition of the pseudocode that is used in this manual, and defines some *helper* procedures and functions that are used by pseudocode. It contains the following sections:

- [About the ARM pseudocode on page K10-6254.](#)
- [Pseudocode for instruction descriptions on page K10-6255.](#)
- [Data types on page K10-6257.](#)
- [Operators on page K10-6262.](#)
- [Statements and control structures on page K10-6268.](#)
- [Built-in functions on page K10-6273.](#)
- [Miscellaneous helper procedures and functions on page K10-6276.](#)
- [ARM pseudocode definition index on page K10-6278.](#)

Note

This appendix is not a formal language definition for the pseudocode. It is a guide to help understand the use of ARM pseudocode. This appendix is not complete. Changes are planned for future releases.

K10.1 About the ARM pseudocode

The ARM pseudocode provides precise descriptions of some areas of the ARM architecture. This includes description of the decoding and operation of all valid instructions. [Pseudocode for instruction descriptions on page K11-6021](#) gives general information about this instruction pseudocode, including its limitations.

The following sections describe the ARM pseudocode in detail:

- [Data types on page K10-6257](#).
- [Operators on page K10-6262](#).
- [Statements and control structures on page K10-6268](#).

[Built-in functions on page K10-6273](#) and [Miscellaneous helper procedures and functions on page K10-6276](#) describe some built-in functions and pseudocode helper functions that are used by the pseudocode functions that are described elsewhere in this manual. [ARM pseudocode definition index on page K10-6278](#) contains the indexes to the pseudocode.

K10.1.1 General limitations of ARM pseudocode

The pseudocode statements IMPLEMENTATION_DEFINED, SEE, UNDEFINED, and UNPREDICTABLE indicate behavior that differs from that indicated by the pseudocode being executed. If one of them is encountered:

- Earlier behavior indicated by the pseudocode is only specified as occurring to the extent required to determine that the statement is executed.
- No subsequent behavior indicated by the pseudocode occurs.

For more information, see [Special statements on page K10-6272](#).

K10.2 Pseudocode for instruction descriptions

Each instruction description includes pseudocode that provides a precise description of what the instruction does, subject to the limitations described in [General limitations of ARM pseudocode on page K10-6254](#) and [Limitations of the instruction pseudocode on page K10-6256](#).

In the instruction pseudocode, instruction fields are referred to by the names shown in the encoding diagram for the instruction. [Instruction encoding diagrams and instruction pseudocode](#) gives more information about the pseudocode provided for each instruction.

K10.2.1 Instruction encoding diagrams and instruction pseudocode

Instruction descriptions in this manual contain:

- An Encoding section, containing one or more encoding diagrams, each followed by some encoding-specific pseudocode that translates the fields of the encoding into inputs for the common pseudocode of the instruction, and picks out any encoding-specific special cases.
- An Operation section, containing common pseudocode that applies to all of the encodings being described. The Operation section pseudocode contains a call to the `EncodingSpecificOperations()` function, either at its start or only after a condition code check performed by `if ConditionPassed()` then.

An encoding diagram specifies each bit of the instruction as one of the following:

- An obligatory 0 or 1, represented in the diagram as 0 or 1. If this bit does not have this value, the encoding corresponds to a different instruction.
- A *should be* 0 or 1, represented in the diagram as (0) or (1). If this bit does not have this value, the instruction is `CONSTRAINED UNPREDICTABLE`. For more information, see [SBZ or SBO fields T32 and A32 in instructions on page K1-6100](#).
- A named single bit or a bit in a named multi-bit field. The `cond` field in bits[31:28] of many A32/T32 instructions has some special rules associated with it.

An encoding diagram matches an instruction if all obligatory bits are identical in the encoding diagram and the instruction, and one of the following is true:

- The encoding diagram is not for an A32/T32 instruction.
- The encoding diagram is for an A32/T32 instruction that does not have a `cond` field in bits[31:28].
- The encoding diagram is for an A32/T32 instruction that has a `cond` field in bits[31:28], and bits[31:28] of the instruction are not `0b1111`.

In the context of the instruction pseudocode, the execution model for an instruction is:

1. Find all encoding diagrams that match the instruction. It is possible that no encoding diagram matches. In that case, abandon this execution model and consult the relevant instruction set chapter instead to find out how the instruction is to be treated. The bit pattern of such an instruction is usually reserved and `UNDEFINED`, though there are some other possibilities. For example, unallocated hint instructions are documented as being reserved and executed as NOPs.
2. If the operation pseudocode for the matching encoding diagrams starts with a condition code check, perform that check. If the condition code check fails, abandon this execution model and treat the instruction as a NOP. If there are multiple matching encoding diagrams, either all or none of their corresponding pieces of common pseudocode start with a condition code check.
3. Perform the encoding-specific pseudocode for each of the matching encoding diagrams independently and in parallel. Each such piece of encoding-specific pseudocode starts with a bitstring variable for each named bit or multi-bit field in its corresponding encoding diagram, named the same as the bit or multi-bit field and initialized with the values of the corresponding bit or bits from the bit pattern of the instruction.

In a few cases, the encoding diagram contains more than one bit or field with same name. In these cases, the values of the different instances of those bits or fields must be identical. The encoding-specific pseudocode contains a special case using the `Consistent()` function to specify what happens if they are not identical. `Consistent()` returns TRUE if all instruction bits or fields with the same name as its argument have the same value, and FALSE otherwise.

If there are multiple matching encoding diagrams, all but one of the corresponding pieces of pseudocode must contain a special case that indicates that it does not apply. Discard the results of all such pieces of pseudocode and their corresponding encoding diagrams.

There is now one remaining piece of pseudocode and its corresponding encoding diagram left to consider. This pseudocode might also contain a special case, most commonly one indicating that it is `CONSTRAINED UNPREDICTABLE`. If so, abandon this execution model and treat the instruction according to the special case.

4. Check the *should be* bits of the encoding diagram against the corresponding bits of the bit pattern of the instruction. If any of them do not match, abandon this execution model and treat the instruction as `CONSTRAINED UNPREDICTABLE`, see [SBZ or SBO fields T32 and A32 in instructions on page K1-6100](#).
5. Perform the rest of the operation pseudocode for the instruction description that contains the encoding diagram. That pseudocode starts with all variables set to the values they were left with by the encoding-specific pseudocode.

The `ConditionPassed()` call in the common pseudocode, if present, performs step 2, and the `EncodingSpecificOperations()` call performs steps 3 and 4.

K10.2.2 Limitations of the instruction pseudocode

The pseudocode descriptions of instruction functionality have a number of limitations. These are mainly due to the fact that, for clarity and brevity, the pseudocode is a sequential and mostly deterministic language.

These limitations include:

- Pseudocode does not describe the ordering requirements when an instruction generates multiple memory accesses. For a description of the ordering requirements on memory accesses see [Ordering constraints on page E2-2766](#).
- Pseudocode does not describe the exact rules when an `UNDEFINED` instruction fails its condition code check. In such cases, the `UNDEFINED` pseudocode statement lies inside the `if ConditionPassed() then ...` structure, either directly or in the `EncodingSpecificOperations()` function call, and so the pseudocode indicates that the instruction executes as a NOP. [Conditional execution of undefined instructions on page G1-4378](#) describes the exact rules.
- Pseudocode does not describe the exact ordering requirements when a single floating-point instruction generates more than one floating-point exception and one or more of those floating-point exceptions is trapped. [Combinations of floating-point exceptions on page E1-2745](#) describes the exact rules.

————— Note —————

There is no limitation in the case where all the floating-point exceptions are untrapped, because the pseudocode specifies the same behavior as the cross-referenced section.

- An exception can be taken during execution of the pseudocode for an instruction, either explicitly as a result of the execution of a pseudocode function such as `Abort()`, or implicitly, for example if an interrupt is taken during execution of an LDM instruction. If this happens, the pseudocode does not describe the extent to which the normal behavior of the instruction occurs. To determine that, see the descriptions of the exceptions in [Handling exceptions that are taken to an Exception level using AArch32 on page G1-4340](#).

K10.3 Data types

This section describes:

- [General data type rules](#).
- [Bitstrings](#).
- [Integers](#) on page K10-6258.
- [Reals](#) on page K10-6258.
- [Booleans](#) on page K10-6258.
- [Enumerations](#) on page K10-6259.
- [Structures](#) on page K10-6259.
- [Tuples](#) on page K10-6260.
- [Arrays](#) on page K10-6261.

K10.3.1 General data type rules

ARM architecture pseudocode is a strongly typed language. Every literal and variable is of one of the following types:

- Bitstring.
- Integer.
- Boolean.
- Real.
- Enumeration.
- Tuple.
- Struct.
- Array.

The type of a literal is determined by its syntax. A variable can be assigned to without an explicit declaration. The variable implicitly has the type of the assigned value. For example, the following assignments implicitly declare the variables `x`, `y` and `z` to have types integer, bitstring of length 1, and Boolean, respectively.

```
x = 1;
y = '1';
z = TRUE;
```

Variables can also have their types declared explicitly by preceding the variable name with the name of the type. The following example declares explicitly that a variable named `count` is an integer.

```
integer count;
```

This is most often done in function definitions for the arguments and the result of the function.

The remaining subsections describe each data type in more detail.

K10.3.2 Bitstrings

This section describes the bitstring data type.

Syntax

`bits(N)` The type name of a bitstring of length `N`.
`bit` A synonym of `bits(1)`.

Description

A bitstring is a finite-length string of 0s and 1s. Each length of bitstring is a different type. The minimum permitted length of a bitstring is 0.

Bitstring constants literals are written as a single quotation mark, followed by the string of 0s and 1s, followed by another single quotation mark. For example, the two constants literals of type bit are '0' and '1'. Spaces can be included in bitstrings for clarity.

The bits in a bitstring are numbered from left to right $N-1$ to 0. This numbering is used when accessing the bitstring using bitslices. In conversions to and from integers, bit $N-1$ is the MSByte and bit 0 is the LSByte. This order matches the order in which bitstrings derived from encoding diagrams are printed.

Every bitstring value has a left-to-right order, with the bits being numbered in standard *little-endian* order. That is, the leftmost bit of a bitstring of length N is bit $(N-1)$ and its right-most bit is bit 0. This order is used as the most-significant-to-least-significant bit order in conversions to and from integers. For bitstring constants and bitstrings that are derived from encoding diagrams, this order matches the way that they are printed.

Bitstrings are the only concrete data type in pseudocode, corresponding directly to the contents values that are manipulated in registers, memory locations, and instructions. All other data types are abstract.

K10.3.3 Integers

This section describes the data type for integer numbers.

Syntax

integer The type name for the integer data type.

Description

Pseudocode integers are unbounded in size and can be either positive or negative. That is, they are mathematical integers rather than what computer languages and architectures commonly call integers. Computer integers are represented in pseudocode as bitstrings of the appropriate length, and the pseudocode provides functions to interpret those bitstrings as integers.

Integer literals are normally written in decimal form, such as 0, 15, -1234. They can also be written in C-style hexadecimal form, such as 0x55 or 0x80000000. Hexadecimal integer literals are treated as positive unless they have a preceding minus sign. For example, 0x80000000 is the integer +2³¹. If -2³¹ needs to be written in hexadecimal, it must be written as -0x80000000.

K10.3.4 Reals

This section describes the data type for real numbers.

Syntax

real The type name for the real data type.

Description

Pseudocode reals are unbounded in size and precision. That is, they are mathematical real numbers, not computer floating-point numbers. Computer floating-point numbers are represented in pseudocode as bitstrings of the appropriate length, and the pseudocode provides functions to interpret those bitstrings as reals.

Real constant literals are written in decimal form with a decimal point. This means 0 is an integer constant literal, but 0.0 is a real constant literal.

K10.3.5 Booleans

This section describes the Boolean data type.

Syntax

`boolean` The type name for the Boolean data type.
`TRUE` The two values a Boolean variable can take.

Description

A Boolean is a logical TRUE or FALSE value.

———— Note —————

This is not the same type as `bit`, which is a bitstring of length 1. A Boolean can only take on one of two values: TRUE or FALSE.

K10.3.6 Enumerations

This section describes the enumeration data type.

Syntax and examples

`enumeration` Keyword to defined a new enumeration type.
`enumeration Example {Example_One, Example_Two, Example_Three};`
 A definition of a new enumeration called `Example`, which can take on the values `Example_One`, `Example_Two`, `Example_Three`.

Description

An enumeration is a defined set of named values.

An enumeration must contain at least one named value. A named value must not be shared between enumerations.

Enumerations must be defined explicitly, although a variable of an enumeration type can be declared implicitly by assigning one of the named values to it. By convention, each named value starts with the name of the enumeration followed by an underscore. The name of the enumeration is its *type name*, or *type*, and the named values are its possible *values*.

K10.3.7 Structures

This section describes the structure data type.

Syntax and examples

`type` The keyword used to declare the structure data type.
`type ShiftSpec is (bits(2) shift, integer amount)`
 An example definition for a new structure called `ShiftSpec` that contains an bitstring member called `shift` and a integer member named `amount`. Structure definitions must not be terminated with a semicolon.
`ShiftSpec abc;`
 A declaration of a variable named `abc` of type `ShiftSpec`.
`abc.shift`
 Syntax to refer to the individual members within the structure variable.

Description

A structure is a compound data type composed of one or more data items. The data items can be of different data types. This can include compound data types. The data items of a structure are called its members and are named.

In the syntax section, the example defines a structure called `ShiftSpec` with two members. The first is a bitstring of length 2 named `shift` and the second is an integer named `amount`. After declaring a variable of that type named `abc`, the members of this structure are referred to as `abc.shift` and `abc.amount`.

Every definition of a structure creates a different type, even if the number and type of their members are identical. For example:

```
type ShiftSpec1 is (bits(2) shift, integer amount)
type ShiftSpec2 is (bits(2) shift, integer amount)
```

`ShiftSpec1` and `ShiftSpec2` are two different types despite having identical definitions. This means that the value in a variable of type `ShiftSpec1` cannot be assigned to variable of type `ShiftSpec2`.

K10.3.8 Tuples

This section describes the tuple data type.

Examples

```
(bits(32) shifter_result, bit shifter_carry_out)
```

An example of the tuple syntax.

```
(shift_t, shift_n) = ('00', 0);
```

An example of assigning values to a tuple.

Description

A tuple is an ordered set of data items, separated by commas and enclosed in parentheses. The items can be of different types and a tuple must contain at least one data item.

Tuples are often used as the return type for functions that return multiple results. For example, in the syntax section, the example tuple is the return type of the function `Shift_C()`, which performs a standard A32/T32 shift or rotation. Its return type is a tuple containing two data items, with the first of type `bits(32)` and the second of type `bit`.

Each tuple is a separate compound data type. The compound data type is represented as a comma-separated list of ordered data types between parentheses. This means that the example tuple at the start of this section is of type `(bits(32), bit)`. The general principle that types can be implied by an assignment extends to implying the type of the elements in the tuple. For example, in the syntax section, the example assignment implicitly declares:

- `shift_t` to be of type `bits(2)`.
- `shift_n` to be of type `integer`.
- `(shift_t, shift_n)` to be a tuple of type `(bits(2), integer)`.

K10.3.9 Arrays

This section describes the array data type.

Syntax

array The type name for the array data type.

```
array data_type array_name[A..B];
```

Declaration of an array of type `data_type`, which might be compound data type. It is named `array_name` and is indexed with an integer range from A to B.

Description

An array is an ordered set of fixed size containing items of a single data type. This can include compound data types. Pseudocode arrays are indexed by either enumerations or integer ranges. An integer range is represented by the lower inclusive end of the range, then `..`, then the upper inclusive end of the range.

For example:

The following example declares an array of 31 bitstrings of length 64, indexed from 0 to 30.

```
array bits(64) _R[0..30];
```

Arrays are always explicitly declared, and there is no notation for a constant literal array. Arrays always contain at least one element data item, because:

- Enumerations always contain at least one symbolic constant named value.
- Integer ranges always contain at least one integer.

An array declared with an enumeration type as the index must be accessed using enumeration values of that enumeration type. An array declared with an integer range type as the index must be accessed using integer values from that inclusive range. Accessing such an array with an integer value outside of the range is a coding error.

Arrays do not usually appear directly in pseudocode. The items that syntactically look like arrays in pseudocode are usually array-like functions such as `R[i]`, `MemU[address, size]` or `Elem[vector, i, size]`. These functions package up and abstract additional operations normally performed on accesses to the underlying arrays, such as register banking, memory protection, endian-dependent byte ordering, exclusive-access housekeeping and Advanced SIMD element processing. See [Function and procedure calls on page K10-6268](#).

K10.4 Operators

This section describes:

- *Relational operators.*
- *Boolean operators.*
- *Bitstring operators on page K10-6263.*
- *Arithmetic operators on page K10-6263.*
- *The assignment operator on page K10-6264.*
- *Precedence rules on page K10-6266.*
- *Conditional expressions on page K10-6266.*
- *Operator polymorphism on page K10-6266.*

K10.4.1 Relational operators

The following operations yield results of type `boolean`.

Equality and non-equality

If two variables `x` and `y` are of the same type, their values can be tested for equality by using the expression `x == y` and for non-equality by using the expression `x != y`. In both cases, the result is of type `boolean`.

Both `x` and `y` must be of type `bits(N)`, `real`, `enumeration`, `boolean`, or `integer`. Named values from an enumeration can only be compared if they are both from the same enumeration. An exception is that a bitstring can be tested for equality with an integer to allow a `d==15` test.

A special form of comparison is defined with a bitstring literal that can contain bit values `'0'`, `'1'`, and `'x'`. Any bit with value `'x'` is ignored in determining the result of the comparison. For example, if `opcode` is a 4-bit bitstring, the expression `opcode == '1x0x'` matches the values `'1000'`, `'1100'`, `'1001'`, and `'1101'`. This is known as a bitmask.

———— Note ————

This special form is permitted in the implied equality comparisons in the `when` parts of `case ... of ...` structures.

Comparisons

If `x` and `y` are integers or reals, then `x < y`, `x <= y`, `x > y`, and `x >= y` are less than, less than or equal, greater than, and greater than or equal comparisons between them, producing Boolean results.

Set membership with `IN`

`<expression> IN {<set>}` produces `TRUE` if `<expression>` is a member of `<set>`. Otherwise, it is `FALSE`. `<set>` must be a list of expressions separated by commas.

K10.4.2 Boolean operators

If `x` is a Boolean expression, then `!x` is its logical inverse.

If `x` and `y` are Boolean expressions, then `x && y` is the result of ANDing them together. As in the C language, if `x` is `FALSE`, the result is determined to be `FALSE` without evaluating `y`.

———— Note ————

This is known as short circuit evaluation.

If `x` and `y` are booleans, then `x || y` is the result of ORing them together. As in the C language, if `x` is `TRUE`, the result is determined to be `TRUE` without evaluating `y`.

Note

If x and y are booleans or Boolean expressions, then the result of $x != y$ is the same as the result of exclusive-ORing x and y together. The operator EOR only accepts bitstring arguments.

K10.4.3 Bitstring operators

The following operations can be applied only to bitstrings.

Logical operations on bitstrings

If x is a bitstring, NOT(x) is the bitstring of the same length obtained by logically inverting every bit of x .

If x and y are bitstrings of the same length, x AND y , x OR y , and x EOR y are the bitstrings of that same length obtained by logically ANDing, logically ORing, and exclusive-ORing corresponding bits of x and y together.

Bitstring concatenation and slicing

If x and y are bitstrings of lengths N and M respectively, then $x:y$ is the bitstring of length $N+M$ constructed by concatenating x and y in left-to-right order.

The bitstring slicing operator addresses specific bits in a bitstring. This can be used to create a new bitstring from extracted bits or to set the value of specific bits. Its syntax is $x<integer_list>$, where x is the integer or bitstring being sliced, and $<integer_list>$ is a comma-separated list of integers enclosed in angle brackets. The length of the resulting bitstring is equal to the number of integers in $<integer_list>$. In $x<integer_list>$, each of the integers in $<integer_list>$ must be:

- ≥ 0 .
- $< \text{Len}(x)$ if x is a bitstring.

The definition of $x<integer_list>$ depends on whether $integer_list$ contains more than one integer:

- If $integer_list$ contains more than one integer, $x<i, j, k, \dots, n>$ is defined to be the concatenation:
 $x<i> : x<j> : x<k> : \dots : x<n>$.
- If $integer_list$ consists of just one integer i , $x<i>$ is defined to be:
 - If x is a bitstring, '0' if bit i of x is a zero and '1' if bit i of x is a one.
 - If x is an integer, and y is the unique integer in the range 0 to $2^{i+1}-1$ that is congruent to x modulo 2^{i+1} . Then $x<i>$ is '0' if $y < 2^i$ and '1' if $y \geq 2^i$.

Loosely, this definition treats an integer as equivalent to a sufficiently long two's complement representation of it as a bitstring.

The notation for a range expression is $i:j$ with $i \geq j$ is shorthand for the integers in order from i down to j , with both end values included. For example, $instr<31:28>$ represents $instr<31, 30, 29, 28>$.

$x<integer_list>$ is assignable provided x is an assignable bitstring and no integer appears more than once in $<integer_list>$. In particular, $x<i>$ is assignable if x is an assignable bitstring and $0 \leq i < \text{Len}(x)$.

Encoding diagrams for registers frequently show named bits or multi-bit fields. For example, the encoding diagram for the APSR shows its bit<31> as N. In such cases, the syntax APSR.N is used as a more readable synonym for APSR<31> as named bits can be referred to with the same syntax as referring to members of a struct. A comma-separated list of named bits enclosed in angle brackets following the register name allows multiple bits to be addressed simultaneously. For example, APSR.<N, C, Q> is synonymous with APSR <31, 29, 27>.

K10.4.4 Arithmetic operators

Most pseudocode arithmetic is performed on integer or real values, with operands obtained by conversions from bitstrings and results converted back to bitstrings. As these data types are the unbounded mathematical types, no issues arise about overflow or similar errors.

Unary plus and minus

If x is an integer or real, then $+x$ is x unchanged, $-x$ is x with its sign reversed. Both are of the same type as x .

Addition and subtraction

If x and y are integers or reals, $x+y$ and $x-y$ are their sum and difference. Both are of type integer if x and y are both of type integer, and real otherwise.

There are two cases where the types of x and y can be different. A bitstring and an integer can be added together to allow the operation $PC + 4$. An integer can be subtracted from a bitstring to allow the operation $PC - 2$.

If x and y are bitstrings of the same length N , so that $N = \text{Len}(x) = \text{Len}(y)$, then $x+y$ and $x-y$ are the least significant N bits of the results of converting x and y to integers and adding or subtracting them. Signed and unsigned conversions produce the same result:

$$\begin{aligned}x+y &= (\text{SInt}(x) + \text{SInt}(y))\langle N-1:0 \rangle \\ &= (\text{UInt}(x) + \text{UInt}(y))\langle N-1:0 \rangle \\ x-y &= (\text{SInt}(x) - \text{SInt}(y))\langle N-1:0 \rangle \\ &= (\text{UInt}(x) - \text{UInt}(y))\langle N-1:0 \rangle\end{aligned}$$

If x is a bitstring of length N and y is an integer, $x+y$ and $x-y$ are the bitstrings of length N defined by $x+y = x + y\langle N-1:0 \rangle$ and $x-y = x - y\langle N-1:0 \rangle$. Similarly, if x is an integer and y is a bitstring of length M , $x+y$ and $x-y$ are the bitstrings of length M defined by $x+y = x\langle M-1:0 \rangle + y$ and $x-y = x\langle M-1:0 \rangle - y$.

Multiplication

If x and y are integers or reals, then $x * y$ is the product of x and y . It is of type integer if x and y are both of type integer, and real otherwise.

Division and modulo

If x and y are reals, then x/y is the result of dividing x by y , and is always of type real.

If x and y are integers, then $x \text{ DIV } y$ and $x \text{ MOD } y$ are defined by:

$$\begin{aligned}x \text{ DIV } y &= \text{RoundDown}(x/y) \\ x \text{ MOD } y &= x - y * (x \text{ DIV } y)\end{aligned}$$

It is a pseudocode error to use any of x/y , $x \text{ MOD } y$, or $x \text{ DIV } y$ in any context where y can be zero.

Scaling

If x and n are of type integer, then:

- $x \ll n = \text{RoundDown}(x * 2^n)$.
- $x \gg n = \text{RoundDown}(x * 2^{(-n)})$.

Raising to a power

If x is an integer or a real and n is an integer then x^n is the result of raising x to the power of n , and:

- If x is of type integer then x^n is of type integer.
- If x is of type real then x^n is of type real.

K10.4.5 The assignment operator

The assignment operator is the $=$ character, which assigns the value of the right-hand side to the left-hand side. An assignment statement takes the form:

```
<assignable_expression> = <expression>;
```

This following subsection defines valid expression syntax.

General expression syntax

An expression is one of the following:

- A literal.
- A variable, optionally preceded by a data type name to declare its type.
- The word UNKNOWN preceded by a data type name to declare its type.
- The result of applying a language-defined operator to other expressions.
- The result of applying a function to other expressions.

Variable names normally consist of alphanumeric and underscore characters, starting with an alphabetic or underscore character.

Each register defined in an ARM architecture specification defines a correspondingly named pseudocode bitstring variable, and that variable has the stated behavior of the register. For example, if a bit of a register is defined as RAZ/WI, then the corresponding bit of its variable reads as '0' and ignore writes.

An expression like `bits(32) UNKNOWN` indicates that the result of the expression is a value of the given type, but the architecture does not specify what value it is and software must not rely on such values. The value produced must not:

- Return information that cannot be accessed at the current or a lower level of privilege using instructions that are not UNPREDICTABLE or CONSTRAINED UNPREDICTABLE and do not return UNKNOWN values,
- Be promoted as providing any useful information to software.

———— Note ————

UNKNOWN values are similar to the definition of UNPREDICTABLE, but do not indicate that the entire architectural state becomes unspecified.

Only the following expressions are assignable. This means that these are the only expressions that can be placed on the left-hand side of an assignment.

- Variables.
- The results of applying some operators to other expressions.
The description of each language-defined operator that can generate an assignable expression specifies the circumstances under which it does so. For example, those circumstances might require that one or more of the expressions the operator operates on is an assignable expression.
- The results of applying array-like functions to other expressions. The description of an array-like function specifies the circumstances under which it can generate an assignable expression.

———— Note ————

If the right-hand side in an assignment is a function returning a tuple, an item in the assignment destination can be written as `-` to indicate that the corresponding item of the assigned tuple value is discarded. For example:

```
(shifted, -) = LSL_C(operand, amount);
```

The expression on the right-hand side itself can be a tuple. For example:

```
(x, y) = (function_1(), function_2());
```

Every expression has a data type.

- For a literal, this data type is determined by the syntax of the literal.
- For a variable, there are the following possible sources for the data type
 - An optional preceding data type name.
 - A data type the variable was given earlier in the pseudocode by recursive application of this rule.

- A data type the variable is being given by assignment, either by direct assignment to the variable, or by assignment to a list of which the variable is a member.

It is a pseudocode error if none of these data type sources exists for a variable, or if more than one of them exists and they do not agree about the type.

- For a language-defined operator, the definition of the operator determines the data type.
- For a function, the definition of the function determines the data type.

K10.4.6 Precedence rules

The precedence rules for expressions are:

1. Literals, variables and function invocations are evaluated with higher priority than any operators using their results, but see [Boolean operators on page K10-6262](#).
2. Operators on integers follow the normal operator precedence rules of *exponentiation before multiply/divide before add/subtract*, with sequences of multiply/divides or add/subtracts evaluated left-to-right.
3. Other expressions must be parenthesized to indicate operator precedence if ambiguity is possible, but need not be if all permitted precedence orders under the type rules necessarily lead to the same result. For example, if *i*, *j* and *k* are integer variables, *i* > 0 && *j* > 0 && *k* > 0 is acceptable, but *i* > 0 && *j* > 0 || *k* > 0 is not.

K10.4.7 Conditional expressions

If *x* and *y* are two values of the same type and *t* is a value of type `boolean`, then `if t then x else y` is an expression of the same type as *x* and *y* that produces *x* if *t* is `TRUE` and *y* if *t* is `FALSE`.

K10.4.8 Operator polymorphism

Operators in pseudocode can be polymorphic, with different functionality when applied to different data types. Each resulting form of an operator has a different prototype definition. For example, the operator `+` has forms that act on various combinations of integers, reals and bitstrings.

[Table K10-1](#) summarizes the operand types valid for each unary operator and the result type. [Table K10-2](#) summarizes the operand types valid for each binary operator and the result type.

Table K10-1 Result and operand types permitted for unary operators

Operator	Operand Type	Result Type
-	integer	integer
	real	real
NOT	bits(N)	bits(N)
!	boolean	boolean

Table K10-2 Result and operand types permitted for binary operators

Operator	First operand type	Second operand type	Result type
==	bits(N)	integer	boolean
		bits(N)	
==	integer	integer	boolean
	real	real	
==	enumeration	enumeration	boolean
	boolean	boolean	

Table K10-2 Result and operand types permitted for binary operators (continued)

Operator	First operand type	Second operand type	Result type
!=	bits(N)	bits(N)	
	integer	integer	boolean
	real	real	
<, >	integer	integer	boolean
	<=, >=	real	
+, -	integer	integer	integer
	real	real	real
	bits(N)	bits(N) integer	bits(N)
<<, >>	integer	integer	integer
	integer	integer	integer
*	real	real	real
	bits(N)	bits(N)	bits(N)
/	real	real	real
DIV	integer	integer	integer
MOD	integer	integer	integer
	bits(N)	integer	
&&,	boolean	boolean	boolean
AND, OR, EOR	bits(N)	bits(N)	bits(N)
^	integer	integer	integer
	real	integer	real

K10.5 Statements and control structures

This section describes the statements and program structures available in the pseudocode:

- [Statements and Indentation](#).
- [Function and procedure calls](#).
- [Conditional control structures](#) on page K10-6270.
- [Loop control structures](#) on page K10-6271.
- [Special statements](#) on page K10-6272.
- [Comments](#) on page K10-6272.

K10.5.1 Statements and Indentation

A simple statement is either an assignment, a function call, or a procedure call. Each statement must be terminated with a semicolon.

Indentation normally indicates the structure in compound statements. The statements contained in structures such as `if ... then ... else ...` or procedure and function definitions are indented more deeply than the statement structure itself. The end of a compound statement structure and their end is indicated by returning to the original indentation level or less.

Indentation is normally done by four spaces for each level. Standard indentation uses four spaces for each level of indent.

K10.5.2 Function and procedure calls

This section describes how functions and procedures are defined and called in the pseudocode.

Procedure and function definitions

A procedure definition has the form:

```
<procedure name>(<argument prototypes>)
  <statement 1>;
  <statement 2>;
  ...
  <statement n>;
```

where <argument prototypes> consists of zero or more argument definitions, separated by commas. Each argument definition consists of a type name followed by the name of the argument.

Note

This first definition line is not terminated by a semicolon. This distinguishes it from a procedure call.

A function definition is similar, but also declares the return type of the function:

```
<return type> <function name>(<argument prototypes>)
  <statement 1>;
  <statement 2>;
  ...
  <statement n>;
```

Note

A function or procedure name can include a ".". This is a convention used for functions that have similar but different behaviors in AArch32 and AArch64 states.

Array-like functions are similar, but are written with square brackets and have two forms. These two forms exist because reading from and writing to an array element require different functions. They are frequently used in memory operations. An array-like function definition with a return type is equivalent to reading from an array. For example:

```
<return type> <function name>[<argument prototypes>]
  <statement 1>;
  <statement 2>;
  ...
  <statement n>;
```

Its related function definition with no return type is equivalent to writing to an array. For example:

```
<function name>[<argument prototypes>] = <value prototype>
  <statement 1>;
  <statement 2>;
  ...
  <statement n>;
```

The value prototype determines what data type can be written to the array. The two related functions must share the same name, but the value prototype and return type can be different.

Procedure calls

A procedure call has the form:

```
<procedure_name>(<arguments>);
```

Return statements

A procedure return has the form:

```
return;
```

A function return has the form:

```
return <expression>;
```

where <expression> is of the type declared in the function prototype line.

K10.5.3 Conditional control structures

This section describes how conditional control structures are used in the pseudocode.

if ... then ... else ...

In addition to being a ternary operator, a multi-line if ... then ... else ... structure can act as a control structure and has the form:

```
if <boolean_expression> then
    <statement 1>;
    <statement 2>;
    ...
    <statement n>;

elsif <boolean_expression> then
    <statement a>;
    <statement b>;
    ...
    <statement z>;
else
    <statement A>;
    <statement B>;
    ...
    <statement Z>;
```

The block of lines consisting of `elsif` and its indented statements is optional, and multiple `elsif` blocks can be used.

The block of lines consisting of `else` and its indented statements is optional.

Abbreviated one-line forms can be used when the `then` part, and in the `else` part if it is present, contain only simple statements such as:

```
if <boolean_expression> then <statement 1>;
if <boolean_expression> then <statement 1>; else <statement A>;
if <boolean_expression> then <statement 1>; <statement 2>; else <statement A>;
```

————— **Note** —————

In these forms, <statement 1>, <statement 2> and <statement A> must be terminated by semicolons. This and the fact that the `else` part is optional distinguish its use as a control structure from its use as a ternary operator.

case ... of ...

A case ... of ... structure has the form:

```
case <expression> of
    when <literal values1>
        <statement 1>;
        <statement 2>;
        ...
        <statement n>;

    when <literal values2>
        <statement 1>;
        <statement 2>;
        ...
        <statement n>;

    ... more "when" groups if required ...
```

```

otherwise
  <statement A>;
  <statement B>;
  ...
  <statement Z>;

```

In this structure, <literal values1> and <literal values2> consist of literal values of the same type as <expression>, separated by commas. There can be additional when groups in the structure. Abbreviated one line forms of when and otherwise parts can be used when they contain only simple statements.

If <expression> has a bitstring type, the literal values can also include bitstring literals containing 'x' bits, known as bitmasks. For details see [Equality and non-equality on page K10-6262](#).

K10.5.4 Loop control structures

This section describes the three loop control structures used in the pseudocode.

repeat ... until ...

A repeat ... until ... structure has the form:

```

repeat
  <statement 1>;
  <statement 2>;
  ...
  <statement n>;
until <boolean_expression>;

```

It executes the statement block at least once, and the loop repeats until <boolean expression> evaluates to TRUE. Variables explicitly declared inside the loop body have scope local to that loop and might not be accessed outside the loop body.

while ... do

A while ... do structure has the form:

```

while <boolean_expression> do
  <statement 1>;
  <statement 2>;
  ...
  <statement n>;

```

It begins executing the statement block only if the Boolean expression is true. The loop then runs until the expression is false.

for ...

A for ... structure has the form:

```

for <assignable_expression> = <integer_expr1> to <integer_expr2>
  <statement 1>;
  <statement 2>;
  ...
  <statement n>;

```

The <assignable_expression> is initialized to <integer_expr1> and compared to <integer_expr2>. If <integer_expr1> is less than <integer_expr2>, the loop body is executed and the <assignable_expression> incremented by one. This repeats until <assignable expression> is more than or equal to <integer_expr2>.

There is an alternate form:

```

for <assignable_expression> = <integer_expr1> downto <integer_expr2>

```

where <integer_expr1> is decremented after the loop body executes and continues until <assignable expression> is less than or equal than <integer_expr2>.

K10.5.5 Special statements

This section describes statements with particular architecturally-defined behaviors.

UNDEFINED

This subsection describes the statement:

```
UNDEFINED;
```

This statement indicates a special case that replaces the behavior defined by the current pseudocode, apart from behavior required to determine that the special case applies. The replacement behavior is that the Undefined Instruction exception is taken.

UNPREDICTABLE

This subsection describes the statement:

```
UNPREDICTABLE;
```

This statement indicates a special case that replaces the behavior defined by the current pseudocode, apart from behavior required to determine that the special case applies. The replacement behavior is UNPREDICTABLE.

SEE...

This subsection describes the statement:

```
SEE <reference>;
```

This statement indicates a special case that replaces the behavior defined by the current pseudocode, apart from behavior required to determine that the special case applies. The replacement behavior is that nothing occurs as a result of the current pseudocode because some other piece of pseudocode defines the required behavior. The <reference> indicates where that other pseudocode can be found.

It usually refers to another instruction, but can also refer to another encoding or note of the same instruction.

IMPLEMENTATION_DEFINED

This subsection describes the statement:

```
IMPLEMENTATION_DEFINED {"<text>"};
```

This statement indicates a special case that replaces the behavior defined by the current pseudocode, apart from behavior required to determine that the special case applies. The replacement behavior is IMPLEMENTATION_DEFINED. An optional <text> field can give more information.

K10.5.6 Comments

The pseudocode supports two styles of comments:

- `//` starts a comment that is terminated by the end of the line.
- `/*` starts a comment that is terminated by `*/`.

`/**/` statements might not be nested, and the first `*/` ends the comment.

———— **Note** —————

Comment lines do not require a terminating semicolon.

K10.6 Built-in functions

This section describes:

- [Bitstring manipulation functions](#).
- [Arithmetic functions](#) on page K10-6274.

K10.6.1 Bitstring manipulation functions

The following bitstring manipulation functions are defined:

Bitstring length and most significant bit

If x is a bitstring:

- The bitstring length function $\text{Len}(x)$ returns the length of x as an integer.

Bitstring concatenation and replication

If x is a bitstring and n is an integer with $n \geq 0$:

- $\text{Replicate}(x, n)$ is the bitstring of length $n \cdot \text{Len}(x)$ consisting of n copies of x concatenated together.
- $\text{Zeros}(n) = \text{Replicate}('0', n)$.
- $\text{Ones}(n) = \text{Replicate}('1', n)$.

Bitstring count

If x is a bitstring, $\text{BitCount}(x)$ is an integer result equal to the number of bits of x that are ones.

Testing a bitstring for being all zero or all ones

If x is a bitstring:

- $\text{IsZero}(x)$ produces TRUE if all of the bits of x are zeros and FALSE if any of them are ones
- $\text{IsZeroBit}(x)$ produces '1' if all of the bits of x are zeros and '0' if any of them are ones.

$\text{IsOnes}(x)$ and $\text{IsOnesBit}(x)$ work in the corresponding ways. This means:

```
IsZero(x)    = (BitCount(x) == 0)
IsOnes(x)    = (BitCount(x) == Len(x))
IsZeroBit(x) = if IsZero(x) then '1' else '0'
IsOnesBit(x) = if IsOnes(x) then '1' else '0'
```

Lowest and highest set bits of a bitstring

If x is a bitstring, and $N = \text{Len}(x)$:

- $\text{LowestSetBit}(x)$ is the minimum bit number of any of the bits of x that are ones. If all of its bits are zeros, $\text{LowestSetBit}(x) = N$.
- $\text{HighestSetBit}(x)$ is the maximum bit number of any of the bits of x that are ones. If all of its bits are zeros, $\text{HighestSetBit}(x) = -1$.
- $\text{CountLeadingZeroBits}(x)$ is the number of zero bits at the left end of x , in the range 0 to N . This means:
 $\text{CountLeadingZeroBits}(x) = N - 1 - \text{HighestSetBit}(x)$.
- $\text{CountLeadingSignBits}(x)$ is the number of copies of the sign bit of x at the left end of x , excluding the sign bit itself, and is in the range 0 to $N-1$. This means:
 $\text{CountLeadingSignBits}(x) = \text{CountLeadingZeroBits}(x \ll N-1 : 1 \gg \text{EOR } x \ll N-2 : 0 \gg)$.

Zero-extension and sign-extension of bitstrings

If x is a bitstring and i is an integer, then $\text{ZeroExtend}(x, i)$ is x extended to a length of i bits, by adding sufficient zero bits to its left. That is, if $i = \text{Len}(x)$, then $\text{ZeroExtend}(x, i) = x$, and if $i > \text{Len}(x)$, then:

```
ZeroExtend(x, i) = Replicate('0', i-Len(x)) : x
```

If x is a bitstring and i is an integer, then $\text{SignExtend}(x, i)$ is x extended to a length of i bits, by adding sufficient copies of its leftmost bit to its left. That is, if $i = \text{Len}(x)$, then $\text{SignExtend}(x, i) = x$, and if $i > \text{Len}(x)$, then:

```
SignExtend(x, i) = Replicate(TopBit(x), i-Len(x)) : x
```

It is a pseudocode error to use either $\text{ZeroExtend}(x, i)$ or $\text{SignExtend}(x, i)$ in a context where it is possible that $i < \text{Len}(x)$.

Converting bitstrings to integers

If x is a bitstring, $\text{SInt}()$ is the integer whose two's complement representation is x .

$\text{UInt}()$ is the integer whose unsigned representation is x .

$\text{Int}(x, \text{unsigned})$ returns either $\text{SInt}(x)$ or $\text{UInt}(x)$ depending on the value of its second argument.

K10.6.2 Arithmetic functions

This section defines built-in arithmetic functions.

Absolute value

If x is either of type real or integer, $\text{Abs}(x)$ returns the absolute value of x . The result is the same type as x .

Rounding and aligning

If x is a real:

- $\text{RoundDown}(x)$ produces the largest integer n such that $n \leq x$.
- $\text{RoundUp}(x)$ produces the smallest integer n such that $n \geq x$.
- $\text{RoundTowardsZero}(x)$ produces:
 - $\text{RoundDown}(x)$ if $x > 0.0$.
 - 0 if $x == 0.0$.
 - $\text{RoundUp}(x)$ if $x < 0.0$.

If x and y are both of type integer, $\text{Align}(x, y) = y * (x \text{ DIV } y)$, and is of type integer.

If x is of type bitstring and y is of type integer, $\text{Align}(x, y) = (\text{Align}(\text{UInt}(x), y)) \langle \text{Len}(x) - 1 : 0 \rangle$, and is a bitstring of the same length as x .

It is a pseudocode error to use either form of $\text{Align}(x, y)$ in any context where y can be 0. In practice, $\text{Align}(x, y)$ is only used with y a constant power of two, and the bitstring form used with $y = 2^n$ has the effect of producing its argument with its n low-order bits forced to zero.

Maximum and minimum

If x and y are integers or reals, then $\text{Max}(x, y)$ and $\text{Min}(x, y)$ are their maximum and minimum respectively. x and y must both be of type integer or of type real. The function returns a value of the same type as its operands.

K10.7 Miscellaneous helper procedures and functions

This section lists the prototypes of miscellaneous *helper* procedures and functions used by the pseudocode, together with a brief description of the effect of the procedure or function. The pseudocode does not define the operation of these helper procedures and functions.

———— **Note** —————

[Chapter J1 ARMv8 Pseudocode](#) also has an entry for each of these functions, but currently these entries do not say anything about the effect of the function. When this information is added in [Chapter J1](#) this section will be removed from the manual.

K10.7.1 EndOfInstruction()

This procedure terminates processing of the current instruction.

```
EndOfInstruction();
```

K10.7.2 Hint_Debug()

This procedure supplies a hint to the debug system.

```
Hint_Debug(bits(4) option);
```

K10.7.3 Hint_PreloadData()

This procedure performs a *preload data* hint.

```
Hint_PreloadData(bits(32) address);
```

K10.7.4 Hint_PreloadDataForWrite()

This procedure performs a *preload data* hint with a probability that the use will be for a write.

```
Hint_PreloadDataForWrite(bits(32) address);
```

K10.7.5 Hint_PreloadInstr()

This procedure performs a *preload instructions* hint.

```
Hint_PreloadInstr(bits(32) address);
```

K10.7.6 Hint_Yield()

This procedure performs a *yield* hint.

```
Hint_Yield();
```

K10.7.7 IsExternalAbort()

This function returns TRUE if the abort currently being processed is an external abort and FALSE otherwise. It is used only in exception entry pseudocode.

```
boolean IsExternalAbort(Fault type)  
    assert type != Fault_None;
```

```
boolean IsExternalAbort(FaultRecord fault);
```

K10.7.8 IsAsyncAbort()

This function returns TRUE if the abort currently being processed is an asynchronous abort, and FALSE otherwise. It is used only in exception entry pseudocode.

```
boolean IsAsyncAbort(Fault type)
    assert type != Fault_None;

boolean IsAsyncAbort(FaultRecord fault);
```

K10.7.9 LSInstructionSyndrome()

This function returns the extended syndrome information for a fault reported in the [HSR](#).

```
bits(11) LSInstructionSyndrome();
```

K10.7.10 ProcessorID()

This function returns an integer that uniquely identifies the executing PE in the system.

```
integer ProcessorID();
```

K10.7.11 RemapRegsHaveResetValues()

This function returns TRUE if the remap registers PRRR and NMRR have their IMPLEMENTATION DEFINED reset values, and FALSE otherwise.

```
boolean RemapRegsHaveResetValues();
```

K10.7.12 ResetControlRegisters()

This function resets the System registers and memory-mapped control registers that have architecturally-defined reset values to those values. For more information about the affected registers see:

- [PE state on reset to AArch64 state on page D1-1796.](#)
- [PE state on reset into AArch32 state on page G1-4400.](#)

```
AArch64.ResetControlRegisters(boolean ResetIsCold)
AArch32.ResetControlRegisters(boolean ResetIsCold)
```

K10.7.13 ThisInstr()

This function returns the bitstring encoding of the currently-executing instruction.

```
bits(32) ThisInstr();
```

———— **Note** —————

Currently, this function is used only on 32-bit instruction encodings.

K10.7.14 ThisInstrLength()

This function returns the length, in bits, of the current instruction. This means it returns 32 or 16:

```
integer ThisInstrLength();
```

K10.8 ARM pseudocode definition index

This section contains the following tables:

- [Table K10-3](#) which contains the pseudocode data types.
- [Table K10-4](#) which contains the pseudocode operators.
- [Table K10-5 on page K10-6279](#) which contains the pseudocode keywords and control structures.
- [Table K10-6 on page K10-6280](#) which contains the statements with special behaviors.

Table K10-3 Index of pseudocode data types

Keyword	Meaning
array	Type name for the array type
bit	Keyword equivalent to bits(1)
bits(N)	Type name for the bitstring of length N data type
boolean	Type name for the Boolean data type
enumeration	Keyword to define a new enumeration type
integer	Type name for the integer data type
real	Type name for the real data type
type	Keyword to define a new structure

Table K10-4 Index of pseudocode operators

Operator	Meaning
-	Unary minus on integers or reals
	Subtraction of integers, reals and bitstrings
	Used in the left-hand side of an assignment or a tuple to discard the result
+	Unary plus on integers or reals
	Addition of integers, reals and bitstrings
.	Extract named member from a list
	Extract named bit or field from a register
:	Bitstring concatenation
	Integer range in bitstring extraction operator
!	Boolean NOT
!=	Comparison for inequality
(...)	Around arguments of procedure or function
[...]	Around array index
	Around arguments of array-like function
*	Multiplication of integers, reals, and bitstrings
/	Division of reals

Table K10-4 Index of pseudocode operators (continued)

Operator	Meaning
&&	Boolean AND
<	<i>Less than</i> comparison of integers and reals
<...>	Slicing of specified bits of bitstring or integer
<<	Multiply integer by power of 2
<=	<i>Less than or equal</i> comparison of integers and reals
=	Assignment operator
==	Comparison for equality
>	<i>Greater than</i> comparison of integers and reals
>=	<i>Greater than or equal</i> comparison of integers and reals
>>	Divide integer by power of 2
	Boolean OR
^	Exponential operator
AND	Bitwise AND of bitstrings
DIV	Quotient from integer division
EOR	Bitwise EOR of bitstrings
IN	Tests membership of a certain expression in a set of values
MOD	Remainder from integer division
NOT	Bitwise inversion of bitstrings
OR	Bitwise OR of bitstrings

Table K10-5 Index of pseudocode keywords and control structures

Operator	Meaning
/*...*/	Comment delimiters
//	Introduces comment terminated by end of line
case ... of ...	Control structure for the
FALSE	One of two values a Boolean can take (other than TRUE)
for ... = ...to ...	Loop control structure, counting up from the initial value to the upper limit
for ... = ... downto ...	Loop control structure, counting down from the initial value to the lower limit
if ... then ... else ...	Condition expression selecting between two values
if ... then ... else ...	Conditional control structure
otherwise	Introduces default case in case ... of ... control structure

Table K10-5 Index of pseudocode keywords and control structures (continued)

Operator	Meaning
repeat ... until ...	Loop control structure that runs at least once until the termination condition is satisfied
return	Procedure or function return
TRUE	One of two values a Boolean can take (other than FALSE)
when	Introduces specific case in case ... of ... control structure
while ... do ...	Loop control structure that runs until the termination condition is satisfied

Table K10-6 Index of special statements

Keyword	Meaning
IMPLEMENTATION_DEFINED	Describes IMPLEMENTATION_DEFINED behavior
SEE	Points to other pseudocode to use instead
UNDEFINED	Cause Undefined Instruction exception
UNKNOWN	Unspecified value
UNPREDICTABLE	Unspecified behavior

Appendix K11

Registers Index

This appendix provides indexes to the register descriptions in this manual. It contains the following sections:

- *Introduction and register disambiguation* on page K11-6282.
- *Alphabetical index of AArch64 registers and system instructions* on page K11-6287.
- *Functional index of AArch64 registers and system instructions* on page K11-6296.
- *Alphabetical index of AArch32 registers and system instructions* on page K11-6306.
- *Functional index of AArch32 registers and system instructions* on page K11-6314.
- *Alphabetical index of memory-mapped registers* on page K11-6324.
- *Functional index of memory-mapped registers* on page K11-6329.

K11.1 Introduction and register disambiguation

In some sections of this manual, registers are referred to by a *general name*, where the description applies to more than one context. Generally, this is one of the following:

- The description applies to both AArch32 state and AArch64 state, and therefore the register names could apply to either AArch32 System registers or AArch64 System registers.
- The description applies to multiple Exception levels, and therefore at a particular Exception level the register names need to take the appropriate Exception. level suffix, `_EL0`, `_EL1`, `_EL2`, or `_EL3`.

The following sections disambiguate the general register names:

- [Register name disambiguation by Execution state.](#)
- [Register name disambiguation by Exception level on page K11-6285.](#)

K11.1.1 Register name disambiguation by Execution state

[Table K11-1](#) disambiguates the general names of the registers by Execution state.

Table K11-1 Disambiguation of general names of registers by Execution state

General name	Short description	AArch64 register	AArch32 register
CONTEXTIDR	Context ID	CONTEXTIDR_EL1	CONTEXTIDR
DBGBCR	Debug Breakpoint Control Registers	DBGBCR<n>_EL1	DBGBCR<n>

VTTBR	<i>VTTBR, Virtualization Translation Table Base Register on page G6-5236</i>

K11.5 Functional index of AArch32 registers and system instructions

This section is an index of the AArch32 registers and system instructions, divided by functional group. Each of the following sections lists the registers for a functional group:

- [Special-purpose registers](#).
- [VMSA-specific registers](#) on page K11-6315.
- [ID registers](#) on page K11-6315.
- [Performance monitors registers](#) on page K11-6317.
- [Debug registers](#) on page K11-6317.
- [Generic timer registers](#) on page K11-6319.
- [Cache maintenance system instructions](#) on page K11-6319.
- [Address translation system instructions](#) on page K11-6320.
- [TLB maintenance system instructions](#) on page K11-6320.
- [Legacy feature registers and system instructions](#) on page K11-6322.
- [Base system registers](#) on page K11-6322.

K11.5.1 Special-purpose registers

This section is an index to the registers in the Processor state registers functional group.

Table K11-17 Special-purpose registers

Register	Description, see
DLR	DLR
DSPSR	DSPSR
ELR_hyp	ELR_hyp
FPSCR	FPSCR
SPSR	SPSR
SPSR_abt	SPSR_abt
SPSR_fiq	SPSR_fiq
SPSR_hyp	SPSR_hyp
SPSR_irq	SPSR_irq
SPSR_mon	SPSR_mon
SPSR_svc	SPSR_svc
SPSR_und	SPSR_und

K11.5.2 VMSA-specific registers

This section is an index to the registers in the Virtual memory control registers functional group.

Table K11-18 VMSA-specific registers

Register	Description, see
AMAIRO	AMAIRO
AMAIR1	AMAIR1
CONTEXTIDR	CONTEXTIDR
DACR	DACR
HAMAIRO	HAMAIRO
HMAIR1	HMAIR1
HMAIRO	HMAIRO
HMAIR1	HMAIR1
HTCR	HTCR
HTTBR	HTTBR
MAIRO	MAIRO
MAIR1	MAIR1
NMRR	NMRR
PRRR	PRRR
TTBCR	TTBCR
TTBCR2	TTBCR2
TTBR0	TTBR0
TTBR1	TTBR1
VTCR	VTCR
VTBR	VTBR

K11.5.3 ID registers

This section is an index to the registers in the Identification registers functional group.

Table K11-19 ID registers

Register	Description, see
AIDR	AIDR
CCSIDR	CCSIDR
CLIDR	CLIDR
CSSELR	CSSELR
CTR	CTR

Table K11-19 ID registers (continued)

Register	Description, see
FPSID	FPSID
ID_AFR0	ID_AFR0
ID_DFR0	ID_DFR0
ID_ISAR0	ID_ISAR0
ID_ISAR1	ID_ISAR1
ID_ISAR2	ID_ISAR2
ID_ISAR3	ID_ISAR3
ID_ISAR4	ID_ISAR4
ID_ISAR5	ID_ISAR5
ID_MMFR0	ID_MMFR0
ID_MMFR1	ID_MMFR1
ID_MMFR2	ID_MMFR2
ID_MMFR3	ID_MMFR3
ID_MMFR4	ID_MMFR4
ID_PFR0	ID_PFR0
ID_PFR1	ID_PFR1
MIDR	MIDR
MPIDR	MPIDR
MVFR0	MVFR0
MVFR1	MVFR1
MVFR2	MVFR2
REVIDR	REVIDR
TCMTR	TCMTR
TLBTR	TLBTR
VMPIDR	VMPIDR
VPIDR	VPIDR

K11.5.4 Performance monitors registers

This section is an index to the registers in the Performance Monitors registers functional group.

Table K11-20 Performance monitors registers

Register	Description, see
PMCCFILTR	PMCCFILTR
PMCCNTR	PMCCNTR
PMCEID0	PMCEID0
PMCEID1	PMCEID1
PMCEID2	PMCEID2
PMCEID3	PMCEID3
PMCNTENCLR	PMCNTENCLR
PMCNTENSET	PMCNTENSET
PMCR	PMCR
PMEVCNTR<n>	PMEVCNTR<n>
PMEVTYPER<n>	PMEVTYPER<n>
PMINTENCLR	PMINTENCLR
PMINTENSET	PMINTENSET
PMOVSRR	PMOVSRR
PMOVSSET	PMOVSSET
PMSELR	PMSELR
PMSWINC	PMSWINC
PMUSERENR	PMUSERENR
PMXVCNTR	PMXVCNTR
PMXEVTYPER	PMXEVTYPER

K11.5.5 Debug registers

This section is an index to the registers in the Debug registers functional group.

Table K11-21 Debug registers

Register	Description, see
DBGAUTHSTATUS	DBGAUTHSTATUS
DBGBCR<n>	DBGBCR<n>
DBGBVR<n>	DBGBVR<n>
DBGBXVR<n>	DBGBXVR<n>
DBGCLAIMCLR	DBGCLAIMCLR

Table K11-21 Debug registers (continued)

Register	Description, see
DBGCLAIMSET	DBGCLAIMSET
DBGDCCINT	DBGDCCINT
DBGDEVID	DBGDEVID

Glossary

- A32 instruction** A word that specifies an operation to be performed by a PE that is executing in an Exception level that is using AArch32 and is in A32 state. A32 instructions must be word-aligned.
- A32 instructions were previously called ARM instructions.
- See also* [A32 state](#), [A64 instruction](#), [T32 instruction](#).
- A32 state** The AArch32 Instruction set state in which the PE executes A32 instructions.
- A32 state was previously called ARM state.
- See also* [T32 instruction](#), [T32 state](#).
- A64 instruction** A word that specifies an operation to be performed by a PE that is executing in an Exception level that is using AArch64. A64 instructions must be word-aligned.
- See also* [A32 instruction](#), [T32 instruction](#).
- AArch32** The 32-bit Execution state. In AArch32 state, addresses are held in 32-bit registers, and instructions in the base instruction sets use 32-bit registers for their processing. AArch32 state supports the T32 and A32 instruction sets
- See also* [AArch64](#), [A32 instruction](#), [T32 instruction](#).
- AArch64** The 64-bit Execution state. In AArch64 state, addresses are held in 64-bit registers, and instructions in the base instruction set can use 64-bit registers for their processing. AArch64 state supports the A64 instruction set.
- See also* [AArch32](#), [A64 instruction](#).
- Abort** An exception caused by an illegal memory access. Aborts can be caused by the external memory system or the MMU.
- Addressing mode** Means a method for generating the memory address used by a load/store instruction.
- Advanced SIMD** A feature of the ARM architecture that provides SIMD operations on a register file of SIMD and floating-point registers. Where an implementation supports both Advanced SIMD and floating-point instructions, these instructions operate on the same register file.

- Aligned** A data item stored at an address that is exactly divisible by the highest power of 2 that divides exactly into its size in bytes. Aligned halfwords, words and doublewords therefore have addresses that are divisible by 2, 4 and 8 respectively.
- An aligned access is one where the address of the access is aligned to the size of each element of the access.
- Architecturally executed** An instruction is architecturally executed only if it would be executed in a simple sequential execution of the program. When such an instruction has been executed and retired it has been *architecturally executed*. Any instruction that, in a simple sequential execution of a program, is treated as a NOP because it fails its condition code check, is an architecturally executed instruction.
- In a PE that performs speculative execution, an instruction is not architecturally executed if the PE discards the results of a speculative execution.
- See also [Condition code check](#), [Simple sequential execution](#).
- Architecturally mapped** Where this manual describes a register as being *architecturally mapped* to another register, this indicates that, in an implementation that supports both of the registers, the two registers access the same state.
- Architecturally UNKNOWN** An architecturally UNKNOWN value is a value that is not defined by the architecture but must meet the requirements of the definition of [UNKNOWN](#). Implementations can define the value of the field, but are not required to do so.
- See also [IMPLEMENTATION DEFINED](#).
- ARM core registers** Some older documentation uses *ARM core registers* to refer to the following set of registers for execution in AArch32 state:
- The 13 general-purpose registers, R0-R12, that software can use for processing.
 - SP, the *stack pointer*, that can also be referred to as R13.
 - LR, the *link register*, that can also be referred to as R14.
 - PC, the *program counter*, that can also be referred to as R15.
- See also [General-purpose registers](#).
- ARM instruction** See [A32 instruction](#).
- Associativity** See [Cache associativity](#).
- Atomicity** Describes either single-copy atomicity or multi-copy atomicity. [Atomicity in the ARM architecture on page B2-82](#) defines these forms of atomicity for the ARM architecture.
- See also [Multi-copy atomicity](#), [Single-copy atomicity](#).
- Banked register** A register that has multiple instances, with the instance that is in use depending on the PE mode, Security state, or other PE state.
- Base register** A register specified by a load/store instruction that is used as the base value for the address calculation for the instruction. Depending on the instruction and its addressing mode, an offset can be added to or subtracted from the base register value to form the virtual address that is sent to memory.
- Base register writeback** Describes writing back a modified value to the base register used in an address calculation.
- Behaves as if** Where this manual indicates that a PE *behaves as if* a certain condition applies, all descriptions of the operation of the PE must be re-evaluated taking account of that condition, together with any other conditions that affect operation.

Big-endian memory

Means that, for example:

- A byte or halfword at a word-aligned address is the most significant byte or halfword in the word at that address.
- A byte at a halfword-aligned address is the most significant byte in the halfword at that address.

See also [Endianness](#), [Little-endian memory](#).

Blocking

Describes an operation that does not permit following instructions to be executed before the operation completes.

A non-blocking operation can permit following instructions to be executed before the operation completes, and in the event of encountering an exception does not signal an exception to the PE. This enables implementations to retire following instructions while the non-blocking operation is executing, without the need to retain precise PE state.

Branch prediction

Is where a PE selects a future execution path to fetch along. For example, after a branch instruction, the PE can choose to speculatively fetch either the instruction following the branch or the instruction at the branch target.

See also [Prefetching](#).

Breakpoint

A debug event triggered by the execution of a particular instruction, specified by one or both of the address of the instruction and the state of the PE when the instruction is executed.

Byte

An 8-bit data item.

Cache associativity

The number of locations in a cache set to which an address can be assigned. Each location is identified by its *way* value.

Cache level

The position of a cache in the cache hierarchy. In the ARM architecture, the lower numbered levels are those closest to the PE. For more information, see [Terms used in describing the cache maintenance instructions on page D3-1981](#).

Cache line

The basic unit of storage in a cache. Its size in words is always a power of two, usually 4 or 8 words. A cache line must be aligned to a suitable memory boundary. A *memory cache line* is a block of memory locations with the same size and alignment as a cache line. Memory cache lines are sometimes loosely called cache lines.

Cache lockdown

Enables critical software and data to be loaded into the cache so that the cache lines containing them are not subsequently reallocated. It alleviates the delays caused by accessing a cache in a worst-case situation. This ensures that all subsequent accesses to the software and data concerned are cache hits and so complete quickly.

Cache miss

A memory access that cannot be processed at high speed because the data it addresses is not in the cache.

Cache sets

Areas of a cache, divided up to simplify and speed up the process of determining whether a cache hit occurs. The number of cache sets is always a power of two.

Cache way

A cache way consists of one cache line from each cache set. The cache ways are indexed from 0 to (Associativity-1). Each cache line in a cache way is chosen to have the same index as the cache way. For example, cache way *n* consists of the cache line with index *n* from each cache set.

Coherence order

See [Coherent](#).

Coherent

Data accesses from a set of observers to a byte in memory are coherent if accesses to that byte in memory by the members of that set of observers are consistent with there being a single total order of all writes to that byte in memory by all members of the set of observers. This single total order of all to writes to that memory location is the *coherence order* for that byte in memory.

Condition code check

The process of determining whether a conditional instruction executes normally or is treated as a NOP. For an instruction that includes a condition code field, that field is compared with the condition flags to determine whether the instruction is executed normally. For a T32 instruction in an IT block, the value of [PSTATE.IT](#) determines whether the instruction is executed normally.

See also [Condition code field](#), [Condition flags](#), [Conditional execution](#).

Condition code field

A 4-bit field in an instruction that specifies the condition under which the instruction executes.

See also [Condition code check](#).

Condition flags

The N, Z, C, and V bits of PSTATE, an SPSR, or FPSCR. See the register descriptions for more information.

See also [Condition code check](#), [PSTATE](#).

Conditional execution

When a conditional instruction starts executing, if the condition code check returns TRUE, the instruction executes normally. Otherwise, it is treated as a NOP.

See also [Condition code check](#).

CONSTRAINED UNPREDICTABLE

Where an instruction can result in UNPREDICTABLE behavior, the ARMv8 architecture specifies a narrow range of permitted behaviors. This range is the range of CONSTRAINED UNPREDICTABLE behavior. All implementations that are compliant with the architecture must follow the CONSTRAINED UNPREDICTABLE behavior.

Execution at Non-secure EL1 or EL0 of an instruction that is CONSTRAINED UNPREDICTABLE can be implemented as generating a trap exception that is taken to EL2, provided that at least one instruction that is not UNPREDICTABLE and is not CONSTRAINED UNPREDICTABLE causes a trap exception that is taken to EL2.

In body text, the term CONSTRAINED UNPREDICTABLE is shown in SMALL CAPITALS.

See also [UNPREDICTABLE](#).

Context switch

The saving and restoring of computational state when switching between different threads or processes. In this manual, the term context switch describes any situation where the context is switched by an operating system and might or might not include changes to the address space.

Context synchronization event

One of:

- Performing an ISB operation. An ISB operation is performed when an ISB instruction is executed and does not fail its condition code check.
- Taking an exception.
- Returning from an exception.
- Exit from Debug state.
- Executing a DCPS instruction.
- Executing a DRPS instruction.

The effects of a Context synchronization event are:

- All unmasked interrupts that are pending at the time of the Context synchronization event are taken before the first instruction after the Context synchronization event.
- If halting is allowed, all Halting debug events that are pending at the time of the Context synchronization event are taken before the first instruction after the Context synchronization event.
- No instructions appearing in program order after an instruction that causes a Context synchronization event will have performed any part of their functionality until the Context synchronization event has occurred.
- All direct and indirect writes to System registers that are made before the Context synchronization event affect any instruction, including a direct read, that appears in program order after the instruction causing the Context synchronization event.
- All invalidations of TLBs, instruction caches, and, in AArch32 state, branch predictors, that are completed before the Context synchronization event affect all instructions that appear in program order after an instruction causing a Context synchronization event.
- In AArch32 state, all Non-cacheable writes that are completed before the Context synchronization event affect all instructions that appear in program order after an instruction causing a Context synchronization event.

- Changes to the Debug external authentication interfaces that are made before the Context synchronization event affect any instruction that appears in program order after the instruction causing the Context synchronization event.

Note

The architecture requires that instructions that generate Context synchronization events do not appear to be executed speculatively, except that it is permissible that the performance counters can reveal such speculation.

Note

Context synchronization events were previously described as *context synchronization operations*.

Debugger	<p>In most of this manual, <i>debugger</i> refers to any agent that is performing debug. However, some chapters or parts of this manual require a more rigorous definition, and define debugger locally. See:</p> <ul style="list-style-type: none"> • Definition of a debugger in the context of self-hosted debug on page D2-1906. • Definition of a debugger in the context of self-hosted debug on page G2-4454. • Definition of a debugger in the context of external debug on page H1-5430.
Deprecated	<p>Something that is present in the ARM architecture for backwards compatibility. Whenever possible software must avoid using deprecated features. Features that are deprecated but are not optional are present in current implementations of the ARM architecture, but might not be present, or might be deprecated and OPTIONAL, in future versions of the ARM architecture.</p> <p>See also OPTIONAL.</p>
Digital signal processing (DSP)	<p>Algorithms for processing signals that have been sampled and converted to digital form. DSP algorithms often use saturated arithmetic.</p>
Direct Memory Access (DMA)	<p>An operation that accesses main memory directly, without the PE performing any accesses to the data concerned.</p>
Direct read	<p>A direct read of a System register is a read performed by a System register access instruction.</p> <p>For more information, see Direct read on page D7-2193.</p> <p>See also Direct write, Indirect read, Indirect write.</p>
Direct write	<p>A direct write of a System register is a write performed by a System register access instruction.</p> <p>For more information, see Direct write on page D7-2193.</p> <p>See also Direct read, Indirect read, Indirect write.</p>
DMA	<p>See Direct Memory Access (DMA).</p>
DNM	<p>See Do-Not-Modify (DNM).</p>
Domain	<p>In the ARM architecture, <i>domain</i> is used in the following contexts.</p> <p>Shareability domain Defines a set of observers for which the shareability attributes make the data or unified caches transparent for data accesses.</p> <p>Power domain Defines a block of logic with a single, common, power supply.</p> <p>Memory regions domain</p> <p>When using the Short-descriptor translation table format, defines a collection of Sections, Large pages and Small pages of memory, that can have their access permissions switched rapidly by writing to the <i>Domain Access Control Register (DACR)</i>. ARM deprecates any use of memory regions domains.</p>

Do-Not-Modify (DNM)

Means the value must not be altered by software. DNM fields read as UNKNOWN values, and must only be written with the value read from the same field on the same PE.

Double-precision value

Consists of two consecutive 32-bit words that are interpreted as a basic double-precision floating-point number according to the *IEEE Standard for Floating-point Arithmetic*.

Doubleword

A 64-bit data item. Doublewords are normally at least word-aligned in ARM systems.

Doubleword-aligned

Means that the address is divisible by 8.

DSP

See [Digital signal processing \(DSP\)](#).

Effective value

A register control field, meaning a field in a register that controls some aspect of the behavior, can be described as having an Effective value:

- In some cases, the description of a control *a* specifies that when control *a* is active it causes a register control field *b* to be treated as having a fixed value for all purposes other than direct reads, or direct reads and direct writes, of the register containing control field *b*. When control *a* is active that fixed value is described as the *Effective value* of register control field *b*. For example, when the value of HCR.DC is 1, the *Effective value* of HCR.VM is 1, regardless of its actual value.

In other cases, in some contexts a register control field *b* is not implemented or is not accessible, but behavior of the PE is as if control field *b* was implemented and accessible, and had a particular value. In this case, that value is the *Effective value* of register control field *b*.

———— **Note** —————

Where a register control field is introduced in a particular version of the architecture, and is not implemented in an earlier version of the architecture, typically it will have an Effective value in that earlier version of the architecture.

- Otherwise, the *Effective value* of a register control field is the value of that field.

Endianness

An aspect of the system memory mapping.

See also [Big-endian memory](#) and [Little-endian memory](#).

Exception

Handles an event. For example, an exception could handle an external interrupt or an undefined instruction.

Exception vector

A fixed address that contains the address of the first instruction of the corresponding exception handler.

Execution stream

The stream of instructions that would have been executed by sequential execution of the program.

Explicit access

A read from memory, or a write to memory, generated by a load or store instruction executed by the PE. Reads and writes generated by hardware translation table accesses are not explicit accesses.

External abort

An abort that is generated by the external memory system.

Fast Context Switch Extension (FCSE)

Modifies the behavior of an ARM memory system to enable multiple programs running on the ARM PE to use identical address ranges, while ensuring that the addresses they present to the rest of the memory system differ. From ARMv6, ARM deprecates any use of the FCSE. The FCSE is:

- Optional in an ARMv7 implementation that does not include the Multiprocessing Extensions.
- Obsolete from the introduction of the Multiprocessing Extensions.

FCSE

See [Fast Context Switch Extension \(FCSE\)](#).

Flat address mapping

Is where the physical address for every access is equal to its virtual address.

Flush-to-zero mode

A processing mode that optimizes the performance of some floating-point algorithms by replacing the denormalized operands and intermediate results with zeros, without significantly affecting the accuracy of their final results.

General-purpose registers

The registers that the base instructions use for processing:

- In AArch32 state the general-purpose registers are R0-R14, that can also be described as R0-R12, SP, LR.

———— **Note** —————

Older documentation defines the AArch32 general-purpose registers as R0-R12, and the ARM core registers as R0-R12, SP, LR, and PC.

- In AArch64 state the general-purpose registers are:
 - W0-W30 when accessed as 32-bit registers.
 - X0-X30 when accessed as 64-bit registers.

See also [High registers](#), [Low registers](#).

Halfword

A 16-bit data item. Halfwords are normally halfword-aligned in ARM systems.

Halfword-aligned

Means that the address is divisible by 2.

High registers

In AArch32 state, the general-purpose registers R8-R14. Most 16-bit T32 instructions cannot access the high registers.

———— **Note** —————

In some contexts, *high registers* refers to R8-R15, meaning R8-R14 and the PC.

See also [General-purpose registers](#), [Low registers](#).

High vectors

An alternative location for the exception vectors. The high vector address range is near the top of the address space, rather than at the bottom.

IGNORED

Indicates that the architecture guarantees that the bit or field is not interpreted or modified by hardware.

In body text, the term IGNORED is shown in SMALL CAPITALS.

Immediate and offset fields

Are unsigned unless otherwise stated.

Immediate value

A value that is encoded directly in the instruction and used as numeric data when the instruction is executed. Many A64, A32, and T32 instructions can be used with an immediate argument.

IMP

An abbreviation used in diagrams to indicate that one or more bits have IMPLEMENTATION DEFINED behavior.

IMPLEMENTATION DEFINED

Means that the behavior is not architecturally defined, but must be defined and documented by individual implementations.

In body text, the term IMPLEMENTATION DEFINED is shown in SMALL CAPITALS.

Index register

A register specified in some load and store instructions. The value of this register is used as an offset to be added to or subtracted from the base register value to form the virtual address that is sent to memory. Some instruction forms permit the index register value to be shifted before the addition or subtraction.

Indirect read

When an instruction uses a System register value to establish operating conditions, that use of the System register is an indirect read of the System register.

For more information, including additional examples of indirect reads, see [Indirect read on page D7-2194](#).

See also [Direct read](#), [Direct write](#), [Indirect write](#).

Indirect write	<p>An indirect write of a System register occurs when the contents of a register are updated by some mechanism other than a <i>Direct write</i> to that register. For example, an indirect write to a register might occur as a side-effect of executing an instruction that does not perform a direct write to the register, or because of some operation performed by an external agent.</p> <p>For more information, see Indirect write on page D7-2194.</p> <p>See also Direct read, Direct write, Indirect read.</p>
Inline literals	<p>These are constant addresses and other data items held in the same area as the software itself. They are automatically generated by compilers, and can also appear in assembler code.</p>
Intermediate physical address (IPA)	<p>An implementation of virtualization, the address to which a Guest OS maps a VA. A hypervisor might then map the IPA to a PA. Typically, the Guest OS is unaware of the translation from IPA to PA.</p> <p>See also Physical address (PA), Virtual address (VA).</p>
Interworking	<p>A method of working that permits branches between software using the A32 and T32 instruction sets.</p>
IPA	<p>See Intermediate physical address (IPA).</p>
Level	<p>See Cache level.</p>
Level of Coherence (LoC)	<p>The last level of cache that must be cleaned or invalidated when cleaning or invalidating to the point of coherency. For more information, see Terms used in describing the cache maintenance instructions on page D3-1981.</p> <p>See also Cache level, Point of coherency (PoC).</p>
Level of Unification, Inner Shareable (LoUIS)	<p>The last level of cache that must be cleaned or invalidated when cleaning or invalidating to the point of unification for the Inner Shareable shareability domain. For more information, see Terms used in describing the cache maintenance instructions on page D3-1981.</p> <p>See also Cache level, Point of unification (PoU).</p>
Level of Unification, uniprocessor (LoUU)	<p>For a PE, the last level of cache that must be cleaned or invalidated when cleaning or invalidating to the point of unification for that PE. For more information, see Terms used in describing the cache maintenance instructions on page D3-1981.</p> <p>See also Cache level, Point of unification (PoU).</p>
Line	<p>See Cache line.</p>
Little-endian memory	<p>Means that, for example:</p> <ul style="list-style-type: none"> • A byte or halfword at a word-aligned address is the least significant byte or halfword in the word at that address. • A byte at a halfword-aligned address is the least significant byte in the halfword at that address. <p>See also Big-endian memory, Endianness.</p>
Load/Store architecture	<p>An architecture where data-processing operations only operate on register contents, not directly on memory contents.</p>
LoC	<p>See Level of Coherence (LoC).</p>
LoUIS	<p>See Level of Unification, Inner Shareable (LoUIS).</p>
LoUU	<p>See Level of Unification, uniprocessor (LoUU).</p>
Lockdown	<p>See Cache lockdown.</p>

- Low registers** In AArch32 state, general-purpose registers R0-R7. Unlike the high registers, all T32 instructions can access the Low registers.
 See also [General-purpose registers](#), [High registers](#).
- Memory barrier** See [Memory barriers on page B2-92](#).
- Memory coherency**
 The problem of ensuring that when a memory location is read, either by a data read or an instruction fetch, the value actually obtained is always the value that was most recently written to the location. This can be difficult when there are multiple possible physical locations, such as main memory and at least one of a write buffer and one or more levels of cache.
- Memory Management Unit (MMU)**
 Provides detailed control of the part of a memory system that provides a single stage of address translation. Most of the control is provided using translation tables that are held in memory, and define the attributes of different regions of the physical memory map.
- Memory Protection Unit (MPU)**
 A hardware unit whose registers provide simple control of a limited number of protection regions in memory.
- Miss** See [Cache miss](#).
- MMU** See [Memory Management Unit \(MMU\)](#).
- MPU** See [Memory Protection Unit \(MPU\)](#).
- Multi-copy atomicity**
 The form of atomicity described in [Requirements for multi-copy atomicity on page B2-83](#).
 See also [Atomicity](#), [Single-copy atomicity](#).
- NaN** Not a Number. A floating-point value that can be used when neither a numeric value nor an infinity is appropriate. A NaN can be a *quiet* NaN, that propagate through most floating-point operations, or a *signaling* NaN, that causes an Invalid Operation floating-point exception when used. For more information, see the *IEEE Standard for Floating-point Arithmetic*.
 See also [Quiet NaN](#), [Signaling NaN](#).
- Natural eviction** A natural eviction is an eviction that occurs in the course of the normal operation of the memory system, rather than because of an operation that explicitly causes an eviction from the cache, such as the execution of a cache maintenance instruction. Typically, a natural eviction occurs when the caching algorithm requires data to be cached but the cache does not have room for that data.
- Observer** A PE or mechanism in the system, such as a peripheral device, that can generate reads from or writes to memory.
- Obsolete** Obsolete indicates something that is no longer supported by ARM. When an architectural feature is described as obsolete, this indicates that the architecture has no support for that feature, although an earlier version of the architecture did support it.
- Offset addressing** Means that the memory address is formed by adding or subtracting an offset to or from the base register value.
- OPTIONAL** When applied to a feature of the architecture, OPTIONAL indicates a feature that is not required in an implementation of the ARM architecture:
- If a feature is OPTIONAL and deprecated, this indicates that the feature is being phased out of the architecture. ARM expects such a features to be included in a new implementation only if there is a known backwards-compatibility reason for the inclusion of the feature.
 A feature that is OPTIONAL and deprecated might not be present in future versions of the architecture.
 - A feature that is OPTIONAL but not deprecated is, typically, a feature added to a version of the ARM architecture after the initial release of that version of the architecture. ARM recommends that such features are included in all new implementations of the architecture.
- In body text, these meanings of the term OPTIONAL are shown in SMALL CAPITALS.

Note

Do not confuse these ARM-specific uses of **OPTIONAL** with other uses of *optional*, where it has its usual meaning. These include:

- Optional arguments in the syntax of many instructions.
- Behavior determined by an implementation choice, for example the optional byte order reversal in an ARMv7-R implementation, where the **SCTLR.IE** bit indicates the implemented option.

See also [Deprecated](#).

PA See [Physical address \(PA\)](#).

PE See [Processing element \(PE\)](#).

Physical address (PA)

An address that identifies a location in the physical memory map.

See also [Intermediate physical address \(IPA\)](#), [Virtual address \(VA\)](#).

PoC See [Point of coherency \(PoC\)](#).

PoU See [Point of unification \(PoU\)](#).

Point of coherency (PoC)

For a particular VA, the point at which all agents that can access memory are guaranteed to see the same copy of a memory location. For more information, see [Terms used in describing the cache maintenance instructions on page D3-1981](#).

Point of unification (PoU)

For a particular PE, the point by which the instruction and data caches and the translation table walks of that PE are guaranteed to see the same copy of a memory location. For more information, see [Terms used in describing the cache maintenance instructions on page D3-1981](#).

Post-indexed addressing

Means that the memory address is the base register value, but an offset is added to or subtracted from the base register value and the result is written back to the base register.

Prefetching

Prefetching refers to speculatively fetching instructions or data from the memory system. In particular, instruction prefetching is the process of fetching instructions from memory before the instructions that precede them, in simple sequential execution of the program, have finished executing. Prefetching an instruction does not mean that the instruction has to be executed.

In this manual, references to instruction or data fetching apply also to prefetching, unless the context explicitly indicates otherwise.

Note

The Prefetch Abort exception can be generated on any instruction fetch, and is not limited to speculative instruction fetches.

See also [Simple sequential execution](#).

Pre-indexed addressing

Means that the memory address is formed in the same way as for offset addressing, but the memory address is also written back to the base register.

Processing element (PE)

The abstract machine defined in the ARM architecture, as documented in an ARM Architecture Reference Manual. A PE implementation compliant with the ARM architecture must conform with the behaviors described in the corresponding ARM Architecture Reference Manual.

Protection region

A memory region whose position, size, and other properties are defined by Memory Protection Unit registers.

Protection Unit See [Memory Protection Unit \(MPU\)](#).

Pseudo-instruction

UAL assembler syntax that assembles to an instruction encoding that is expected to disassemble to a different assembler syntax, and is described in this manual under that other syntax. For example, `MOV <Rd>, <Rm>, LSL #<n>` is a pseudo-instruction that is expected to disassemble as `LSL <Rd>, <Rm>, #<n>`.

PSTATE An abstraction of process state information. All of the instruction sets provide instructions that operate on elements of PSTATE.

See also [Condition flags](#).

Quadword A 128-bit data item. Quadwords are normally at least word-aligned in ARM systems.

Quadword-aligned

Means that the address is divisible by 16.

Quiet NaN A NaN that propagates unchanged through most floating-point operations.

See also [NaN](#), [Signaling NaN](#).

RAO See [Read-As-One \(RAO\)](#).

RAZ See [Read-As-Zero \(RAZ\)](#).

RAO/SBOP In versions of the ARM architecture before ARMv8, Read-As-One, Should-Be-One-or-Preserved on writes. In ARMv8, RES1 replaces this description.

See also [UNK/SBOP](#), [Read-As-One \(RAO\)](#), [RES1](#), [Should-Be-One-or-Preserved \(SBOP\)](#).

RAO/WI Read-As-One, Writes Ignored.

Hardware must implement the field as Read-as-One, and must ignore writes to the field.

Software can rely on the field reading as all 1s, and on writes being ignored.

This description can apply to a single bit that reads as 1, or to a field that reads as all 1s.

See also [Read-As-One \(RAO\)](#).

RAZ/SBZP In versions of the ARM architecture before ARMv8, Read-As-Zero, Should-Be-Zero-or-Preserved on writes. In ARMv8, RES0 replaces this description.

See also [UNK/SBZP](#), [Read-As-Zero \(RAZ\)](#), [RES0](#), [Should-Be-Zero-or-Preserved \(SBZP\)](#).

RAZ/WI Read-As-Zero, Writes Ignored.

Hardware must implement the field as Read-as-Zero, and must ignore writes to the field.

Software can rely on the field reading as all 0s, and on writes being ignored.

This description can apply to a single bit that reads as 0, or to a field that reads as all 0s.

See also [Read-As-Zero \(RAZ\)](#).

Read-allocate cache

A cache in which a cache miss on reading data causes a cache line to be allocated into the cache.

Read-As-One (RAO)

Hardware must implement the field as reading as all 1s.

Software:

- Can rely on the field reading as all 1s.
- Must use a [SBOP](#) policy to write to the field.

This description can apply to a single bit that reads as 1, or to a field that reads as all 1s.

See also [RAO/SBOP](#), [RAO/WI](#), [RES1](#).

Read-As-Zero (RAZ)

Hardware must implement the field as reading as all 0s.

Software:

- Can rely on the field reading as all 0s
- Must use a [SBZP](#) policy to write to the field.

This description can apply to a single bit that reads as 0, or to a field that reads as all 0s.

See also [RAZ/SBZP](#), [RAZ/WI](#), [RES0](#).

Read, modify, write

In a read, modify, write instruction sequence, a value is read to a general-purpose register, the relevant fields updated in that register, and the new value written back.

RES0

A reserved bit. Used for fields in register descriptions, and for fields in architecturally-defined data structures that are held in memory, for example in translation table descriptors.

Within the architecture, there are some cases where a register bit or field:

- Is RES0 in some defined architectural context.
- Has different defined behavior in a different architectural context.

Note

- RES0 is not used in descriptions of instruction encodings.
 - Where an AArch32 System register is *Architecturally mapped* to an AArch64 System register, and a bit or field in that register is RES0 in one Execution state and has defined behavior in the other Execution state, this is an example of a bit or field with behavior that depends on the architectural context.
-

This means the definition of RES0 for fields in read/write registers is:

If a bit is RES0 in all contexts

For a bit in a read/write register, it is IMPLEMENTATION DEFINED whether:

1. The bit is hardwired to 0. In this case:
 - Reads of the bit always return 0.
 - Writes to the bit are ignored.
2. The bit can be written. In this case:
 - An indirect write to the register sets the bit to 0.
 - A read of the bit returns the last value successfully written, by either a direct or an indirect write, to the bit.
If the bit has not been successfully written since reset, then the read of the bit returns the reset value if there is one, or otherwise returns an UNKNOWN value.
 - A direct write to the bit must update a storage location associated with the bit.
 - The value of the bit must have no effect on the operation of the PE, other than determining the value read back from the bit, unless this Manual explicitly defines additional properties for the bit.

Whether RES0 bits or fields follow behavior 1 or behavior 2 is IMPLEMENTATION DEFINED on a field-by-field basis.

If a bit is RES0 only in some contexts

For a bit in a read/write register, when the bit is described as RES0:

- An indirect write to the register sets the bit to 0.
- A read of the bit must return the value last successfully written to the bit, by either a direct or an indirect write, regardless of the use of the register when the bit was written.
If the bit has not been successfully written since reset, then the read of the bit returns the reset value if there is one, or otherwise returns an UNKNOWN value.

- A direct write to the bit must update a storage location associated with the bit.
- While the use of the register is such that the bit is described as RES0, the value of the bit must have no effect on the operation of the PE, other than determining the value read back from that bit, unless this Manual explicitly defines additional properties for the bit.

Considering only contexts that apply to a particular implementation, if there is a context in which a bit is defined as RES0, another context in which the same bit is defined as RES1, and no context in which the bit is defined as a functional bit, then it is IMPLEMENTATION DEFINED whether:

- Writes to the bit are ignored, and reads of the bit return an UNKNOWN value.
- The value of the bit can be written, and a read returns the last value written to the bit.

The RES0 description can apply to bits or fields that are read-only, or are write-only:

- For a read-only bit, RES0 indicates that the bit reads as 0, but software must treat the bit as UNKNOWN.
- For a write-only bit, RES0 indicates that software must treat the bit as SBZ.

A bit that is RES0 in a context is reserved for possible future use in that context. To preserve forward compatibility, software:

- Must not rely on the bit reading as 0.
- Must use an SBZP policy to write to the bit.

This RES0 description can apply to a single bit, or to a field for which each bit of the field must be treated as RES0.

In body text, the term RES0 is shown in SMALL CAPITALS.

See also [Read-As-Zero \(RAZ\)](#), [RES1](#), [Should-Be-Zero-or-Preserved \(SBZP\)](#), [UNKNOWN](#).

RES1

A reserved bit. Used for fields in register descriptions, and for fields in architecturally-defined data structures that are held in memory, for example in translation table descriptors.

Within the architecture, there are some cases where a register bit or field:

- Is RES1 in some defined architectural context.
- Has different defined behavior in a different architectural context.

————— Note —————

- RES1 is not used in descriptions of instruction encodings.
- Where an AArch32 System register is *Architecturally mapped* to an AArch64 System register, and a bit or field in that register is RES1 in one Execution state and has defined behavior in the other Execution state, this is an example of a bit or field with behavior that depends on the architectural context.

This means the definition of RES1 for fields in read/write registers is:

If a bit is RES1 in all contexts

For a bit in a read/write register, it is IMPLEMENTATION DEFINED whether:

1. The bit is hardwired to 1. In this case:
 - Reads of the bit always return 1.
 - Writes to the bit are ignored.
2. The bit can be written. In this case:
 - An indirect write to the register sets the bit to 1.
 - A read of the bit returns the last value successfully written, by either a direct or an indirect write, to the bit.
If the bit has not been successfully written since reset, then the read of the bit returns the reset value if there is one, or otherwise returns an UNKNOWN value.
 - A direct write to the bit must update a storage location associated with the bit.
 - The value of the bit must have no effect on the operation of the PE, other than determining the value read back from the bit, unless this Manual explicitly defines additional properties for the bit.

Whether RES1 bits or fields follow behavior 1 or behavior 2 is IMPLEMENTATION DEFINED on a field-by-field basis.

If a bit is RES1 only in some contexts

For a bit in a read/write register, when the bit is described as RES1:

- An indirect write to the register sets the bit to 1.
- A read of the bit must return the value last successfully written to the bit, regardless of the use of the register when the bit was written.

————— Note —————

As indicated in this list, this value might be written by an indirect write to the register.

If the bit has not been successfully written since reset, then the read of the bit returns the reset value if there is one, or otherwise returns an UNKNOWN value.

- A direct write to the bit must update a storage location associated with the bit.
- While the use of the register is such that the bit is described as RES1, the value of the bit must have no effect on the operation of the PE, other than determining the value read back from that bit, unless this Manual explicitly defines additional properties for the bit.

Considering only contexts that apply to a particular implementation, if there is a context in which a bit is defined as RES0, another context in which the same bit is defined as RES1, and no context in which the bit is defined as a functional bit, then it is IMPLEMENTATION DEFINED whether:

- Writes to the bit are ignored, and reads of the bit return an UNKNOWN value.
- The value of the bit can be written, and a read returns the last value written to the bit.

The RES1 description can apply to bits or fields that are read-only, or are write-only:

- For a read-only bit, RES1 indicates that the bit reads as 1, but software must treat the bit as UNKNOWN.
- For a write-only bit, RES1 indicates that software must treat the bit as SBO.

A bit that is RES1 in a context is reserved for possible future use in that context. To preserve forward compatibility, software:

- Must not rely on the bit reading as 1.
- Must use an SBOP policy to write to the bit.

This RES1 description can apply to a single bit, or to a field for which each bit of the field must be treated as RES1.

In body text, the term RES1 is shown in SMALL CAPITALS.

See also [Read-As-One \(RAO\)](#), [RES0](#), [Should-Be-One-or-Preserved \(SBOP\)](#), [UNKNOWN](#).

Reserved

Unless otherwise stated:

- Instructions that are reserved or that access reserved registers have UNPREDICTABLE or CONSTRAINED UNPREDICTABLE behavior.
- Bit positions described as reserved are:
 - In an RW or WO register, RES0.
 - In an RO register, UNK.

See also [CONSTRAINED UNPREDICTABLE](#), [RES0](#), [RES1](#), [UNDEFINED](#), [UNK](#), [UNPREDICTABLE](#).

RISC

Reduced Instruction Set Computer.

Rounding error

The value of the rounded result of an arithmetic operation minus the exact result of the operation.

Rounding mode

Specifies how the exact result of a floating-point operation is rounded to a value that is representable in the destination format. The rounding modes are defined by the *IEEE Standard for Floating-point Arithmetic*, see [Floating-point standards, and terminology on page A1-49](#).

Saturated arithmetic

Integer arithmetic in which a result that would be greater than the largest representable number is set to the largest representable number, and a result that would be less than the smallest representable number is set to the smallest representable number. Signed saturated arithmetic is often used in DSP algorithms. It contrasts with the normal signed integer arithmetic used in ARM processors, in which overflowing results wrap around from $+2^{31}-1$ to -2^{31} or vice versa.

SBO See [Should-Be-One \(SBO\)](#).

SBOP See [Should-Be-One-or-Preserved \(SBOP\)](#).

SBZ See [Should-Be-Zero \(SBZ\)](#).

SBZP See [Should-Be-Zero-or-Preserved \(SBZP\)](#).

Security hole

A mechanism by which execution at the current level of privilege can achieve an outcome that cannot be achieved at the current or a lower level of privilege using instructions that are not UNPREDICTABLE and are not CONSTRAINED UNPREDICTABLE. The ARM architecture forbids security holes.

See also [CONSTRAINED UNPREDICTABLE](#), [UNPREDICTABLE](#).

Self-modifying code

Code that writes one or more instructions to memory and then executes them. When using self-modifying code, you must use cache maintenance and barrier instructions to ensure synchronization. For more information, see [Caches and memory hierarchy on page B2-97](#).

Set See [Cache sets](#).

Should-Be-One (SBO)

Hardware must ignore writes to the field.

ARM strongly recommends that software writes the field as all 1s. If software writes a value that is not all 1s, it must expect an UNPREDICTABLE or CONSTRAINED UNPREDICTABLE result.

This description can apply to a single bit that should be written as 1, or to a field that should be written as all 1s.

See also [CONSTRAINED UNPREDICTABLE](#), [UNPREDICTABLE](#).

Should-Be-One-or-Preserved (SBOP)

From the introduction of the ARMv8 architecture, the description *Should-Be-One-or-Preserved (SBOP)* is superseded by [RESI](#).

Note

The ARMv7 Large Physical Address Extension modified the definition of SBOP for register bits that are SBOP in some but not all contexts. The behavior of these bits is covered by the [RESI](#) definition, but not by the generic definition of SBOP given here.

Hardware must ignore writes to the field.

When writing this field, software must either write all 1s to this field or, if the register is being restored from a previously read state, write the previously read value to this field. If this is not done, then the result is UNPREDICTABLE.

This description can apply to a single bit that should be written as its preserved value or as 1, or to a field that should be written as its preserved value or as all 1s.

See also [CONSTRAINED UNPREDICTABLE](#), [UNPREDICTABLE](#).

Should-Be-Zero (SBZ)

Hardware must ignore writes to the field.

ARM strongly recommends that software writes the field as all 0s. If software writes a value that is not all 0s, it must expect an UNPREDICTABLE or CONSTRAINED UNPREDICTABLE result.

This description can apply to a single bit that should be written as 0, or to a field that should be written as all 0s.

See also [CONSTRAINED UNPREDICTABLE](#), [UNPREDICTABLE](#).

Should-Be-Zero-or-Preserved (SBZP)

From the introduction of the ARMv8 architecture, the description *Should-Be-Zero-or-Preserved (SBZP)* is superseded by [RES0](#).

Note

The ARMv7 Large Physical Address Extension modified the definition of SBZP for register bits that are SBZP in some but not all contexts. The behavior of these bits is covered by the [RES0](#) definition, but not by the generic definition of SBZP given here.

Hardware must ignore writes to the field.

When writing this field, software must either write all 0s to this field or, if the register is being restored from a previously read state, write the previously read value to this field. If this is not done, then the result is UNPREDICTABLE.

This description can apply to a single bit that should be written as its preserved value or as 0, or to a field that should be written as its preserved value or as all 0s.

See also [CONSTRAINED UNPREDICTABLE](#), [UNPREDICTABLE](#).

Signaling NaN

An Invalid Operation floating-point exception occurs whenever any floating-point operation receives a signaling NaN as an operand. Signaling NaNs can be used in debugging, to track down some uses of uninitialized variables.

See also [NaN](#), [Quiet NaN](#).

Signed immediate and offset fields

Are encoded in two's complement notation unless otherwise stated.

SIMD

Single-Instruction, Multiple-Data.

The SIMD instructions in AArch32 state are:

- The instructions summarized in [Parallel addition and subtraction instructions on page F1-2818](#).
- The Advanced SIMD instructions summarized in [Advanced SIMD and floating-point instructions on page E1-2740](#), when operating on vectors.

Note

In ARMv7, some VFP instructions can operate on vectors. However, ARM deprecates those instruction uses, and strongly recommends that Advanced SIMD instructions are always used for vector operations.

Simple sequential execution

The behavior of an implementation that fetches, decodes and completely executes each instruction before proceeding to the next instruction. Such an implementation performs no speculative accesses to memory, including to instruction memory. The implementation does not pipeline any phase of execution. In practice, this is the theoretical execution model that the architecture is based on, and ARM does not expect this model to correspond to a realistic implementation of the architecture.

Single-copy atomicity

The form of atomicity described in [Properties of single-copy atomic accesses on page B2-83](#).

See also [Atomicity](#), [Multi-copy atomicity](#).

Single-precision value

A 32-bit word that is interpreted as a basic single-precision floating-point number according to the *IEEE Standard for Floating-point Arithmetic*.

Spatial locality

The observed effect that after a program has accessed a memory location, it is likely to also access nearby memory locations in the near future. Caches with multi-word cache lines exploit this effect to improve performance.

Speculative

Speculative operations are:

- Operations that are generated by instructions that appear in the Execution stream after a branch that is not architecturally resolved.
- Operations that are generated by instructions that appear in the Execution stream after an instruction where a synchronous exception condition has not been architecturally resolved.
- Operations that are generated by conditional instructions for which the conditions for the instruction have not been architecturally resolved.
- Operations that are generated by instructions that appear in the Execution stream after the point at which a precise asynchronous exception will be taken.
- Reads or writes generated by load or store instructions for which the data being written or the address being accessed comes from a register that has not been architecturally resolved.
- Operations generated by the hardware that are not directly generated by any instructions appearing in the Execution stream.

See also [Execution stream](#).

Special-purpose register

One of a specified set of registers for which all direct and indirect reads and writes to the register appear to occur in program order relative to other instructions, without the need for any explicit synchronization:

- [Special-purpose registers on page C5-336](#) specifies the AArch64 Special-purpose registers.
- [AArch32 Special-purpose registers on page G1-4328](#) lists the AArch32 Special-purpose registers.

T32 instruction

One or two halfwords that specify an operation to be performed by a PE that is executing in an Exception level that is using AArch32 and is in T32 state. T32 instructions must be halfword-aligned.

T32 instructions were previously called Thumb instructions.

See also [A32 instruction](#), [A64 instruction](#), [T32 state](#).

T32 state

The AArch32 Instruction set state in which the PE executes T32 instructions.

T32 state was previously called Thumb state.

See also [A32 state](#), [T32 instruction](#).

Taken locally

An exception that is taken locally means an exception that is taken to the default Exception level, and is not routed to another Exception level.

Temporal locality

The observed effect that after a program has accesses a memory location, it is likely to access the same memory location again in the near future. Caches exploit this effect to improve performance.

Thumb instruction

See [T32 instruction](#).

TLB

See [Translation Lookaside Buffer \(TLB\)](#).

TLB lockdown

A way to prevent specific translation table walk results being accessed. This ensures that accesses to the associated memory areas never cause a translation table walk.

Translation Lookaside Buffer (TLB)

A memory structure containing the results of translation table walks. They help to reduce the average cost of a memory access. Usually, there is a TLB for each memory interface of the ARM implementation.

Translation table

A table held in memory that defines the properties of memory areas of various sizes from 1KB to 1MB.

Translation table walk

The process of doing a full translation table lookup. It is performed automatically by hardware.

Trap enable bits

In VFPv2, VFPv3U, and VFPv4U, determine whether trapped or untrapped exception handling is selected. If trapped exception handling is selected, the way it is carried out is IMPLEMENTATION DEFINED.

Unaligned

An unaligned access is an access where the address of the access is not aligned to the size of an element of the access.

Unaligned memory accesses

Are memory accesses that are not, or might not be, appropriately halfword-aligned, word-aligned, or doubleword-aligned.

Unallocated

Except where otherwise stated in this manual, an instruction encoding is unallocated if the architecture does not assign a specific function to the entire bit pattern of the instruction, but instead describes it as CONSTRAINED UNPREDICTABLE, UNDEFINED, UNPREDICTABLE, or as an unallocated hint instruction.

A bit in a register is unallocated if the architecture does not assign a function to that bit.

See also [CONSTRAINED UNPREDICTABLE](#), [UNDEFINED](#), [UNPREDICTABLE](#).

UNDEFINED

Indicates cases where an attempt to execute a particular encoding bit pattern generates an exception, that is taken to the current Exception level, or to the default Exception level for taking exceptions if the UNDEFINED encoding was executed at EL0. This applies to:

- Any encoding that is not allocated to any instruction.
- Any encoding that is defined as never accessible at the current Exception level.
- Some cases where an enable, disable, or trap control means an encoding is not accessible at the current Exception level.

If the generated exception is taken to an Exception level that is using AArch32 then it is taken as an Undefined Instruction exception.

———— **Note** —————

On reset, the default Exception level for taking exceptions from EL0 is EL1. However, an implementation might include controls that can change this, effectively making EL1 inactive. See the description of the Exception model for more information

In body text, the term UNDEFINED is shown in SMALL CAPITALS.

See also [Undefined Instruction exception on page G1-4376](#).

Unified cache

Is a cache used for both processing instruction fetches and processing data loads and stores.

Unindexed addressing

Means addressing in which the base register value is used directly as the virtual address to send to memory, without adding or subtracting an offset. In most types of load/store instruction, unindexed addressing is performed by using offset addressing with an immediate offset of 0.

In ARMv7 and earlier versions of the ARM architecture, and in the M-profile, the LDC, LDC2, STC, and STC2 instructions have an explicit unindexed addressing mode that permits the offset field in the instruction to specify additional coprocessor options.

UNK

An abbreviation indicating that software must treat a field as containing an UNKNOWN value.

Hardware must implement the bit as read as 0, or all 0s for a multi-bit field. Software must not rely on the field reading as zero.

See also [UNKNOWN](#).

UNK/SBOP

Hardware must implement the field as Read-As-One, and must ignore writes to the field.

Software must not rely on the field reading as all 1s, and except for writing back to the register it must treat the value as if it is UNKNOWN. Software must use an SBOP policy to write to the field.

This description can apply to a single bit that should be written as its preserved value or as 1, or to a field that should be written as its preserved value or as all 1s.

See also [Read-As-One \(RAO\)](#), [Should-Be-One-or-Preserved \(SBOP\)](#), [UNKNOWN](#).

UNK/SBZP

Hardware must implement the bit as Read-As-Zero, and must ignore writes to the field.

Software must not rely on the field reading as all 0s, and except for writing back to the register must treat the value as if it is UNKNOWN. Software must use an SBZP policy to write to the field.

This description can apply to a single bit that should be written as its preserved value or as 0, or to a field that should be written as its preserved value or as all 0s.

See also [Read-As-Zero \(RAZ\)](#), [Should-Be-Zero-or-Preserved \(SBZP\)](#), [UNKNOWN](#).

UNKNOWN

An UNKNOWN value does not contain valid data, and can vary from moment to moment, instruction to instruction, and implementation to implementation. An UNKNOWN value must not return information that cannot be accessed at the current or a lower level of privilege using instructions that are not UNPREDICTABLE, are not CONSTRAINED UNPREDICTABLE, and do not return UNKNOWN values.

An UNKNOWN value must not be documented or promoted as having a defined value or effect.

In body text, the term UNKNOWN is shown in SMALL CAPITALS.

See also [CONSTRAINED UNPREDICTABLE](#), [UNDEFINED](#), [UNK](#), [UNPREDICTABLE](#).

UNPREDICTABLE

Means the behavior cannot be relied upon. UNPREDICTABLE behavior must not perform any function that cannot be performed at the current or a lower level of privilege using instructions that are not UNPREDICTABLE.

UNPREDICTABLE behavior must not be documented or promoted as having a defined effect.

An instruction that is UNPREDICTABLE can be implemented as UNDEFINED.

Execution at Non-secure EL1 or EL0 of an instruction that is UNPREDICTABLE can be implemented as generating a trap exception that is taken to EL2, provided that at least one instruction that is not UNPREDICTABLE and is not CONSTRAINED UNPREDICTABLE causes a trap exception that is taken to EL2.

In body text, the term UNPREDICTABLE is shown in SMALL CAPITALS.

See also [CONSTRAINED UNPREDICTABLE](#), [UNDEFINED](#).

VA

See [Virtual address \(VA\)](#).

VFP

In ARMv7, an extension to the ARM architecture, that provides single-precision and double-precision floating-point arithmetic.

Virtual address (VA)

An address generated by an ARM PE. This means it is an address that might be held in the program counter of the PE. For a PMSA implementation, the virtual address is identical to the physical address.

See also [Intermediate physical address \(IPA\)](#), [Physical address \(PA\)](#).

Watchpoint

A debug event triggered by an access to memory, specified in terms of the address of the location in memory being accessed.

Way

See [Cache way](#).

WI

Writes Ignored. In a register that software can write to, a WI attribute applied to a bit or field indicates that the bit or field ignores the value written by software and retains the value it had before that write.

See also [RAO/WI](#), [RAZ/WI](#), [RES0](#), [RES1](#).

Word

A 32-bit data item. Words are normally word-aligned in ARM systems.

Word-aligned

Means that the address is divisible by 4.

Write-allocate cache

A cache in which a cache miss on storing data causes a cache line to be allocated into the cache.

Write-back cache

A cache in which when a cache hit occurs on a store access, the data is only written to the cache. Data in the cache can therefore be more up-to-date than data in main memory. Any such data is written back to main memory when the cache line is cleaned or reallocated. Another common term for a write-back cache is a *copy-back cache*.

Write-through cache

A cache in which when a cache hit occurs on a store access, the data is written both to the cache and to main memory. This is normally done via a write buffer, to avoid slowing down the PE.

Write buffer

A block of high-speed memory that optimizes stores to main memory.
